THE early collapse of the summer occupants and the dry time experienced of late has been very favourable for the work of clearing and replanting the beds. It should be remembered that many of the summer bedding plants, as well as the hardy Wallflowers, Forget-me-nots, Silenes, and Saponarias, greatly impoverish the soil, and unless the beds are dressed with fairly rich compost or short manure at least every second year, it soon becomes too poor to cause a healthy growth. In many instances this can better be done now than in the spring or early summer months when so many other matters require attention. The best material for improving the fertility of the soil, and also to otherwise benefit it, will be found in a well-decayed heap of leaves, garden refuse, edgings of turf and lawn grass, which ought to be taken good care of in all gardens. Failing this, substitute either old hotbed manure and soil, or good leaf soil, the last-named being freely used on heavy soils. In refilling the beds, all the plants, shrubs, and Conifers used should be moved as carefully as possible, preserving a good ball of soil about the roots in every case. In order to be effective they ought to nearly or quite touch each other, as few of the plants used make any progress before the spring or flowering time. All should be firmly planted, or otherwise a moderately severe frost will upheave the greater portion of them. Owing to the comparative dryness of the season it may be necessary to water many of the plants and shrubs a few hours prior to removing them, and again after they are replanted.

Many bulbs are available for the decoration of borders and flower beds, and seeing that these can be bought at a cheap rate, and in most instances flower when the ordinary winter bedding plants are still flowerless, no good reason exists for so few, comparatively speaking, being planted. The present is a good time to purchase and plant the majority of those included in the advertised collections, and many beautiful species may also be ordered separately. Whether they shall be planted in beds or in borders where they may remain undisturbed for years, must depend upon circumstances, and no one need hesitate to commence their culture under the impression they are at all difficult to manage and flower.

ANEMONES.

The single varieties sold especially for bedding purposes, notably the showy and early-flowering *Anemone fulgens* and the Peacock Anemones, are frequently planted in masses or single lines, and are very effective early in the spring. They ought to be covered with about 3 inches of soil, taking care to plant them eyes upwards, and they may be about 6 inches apart each way. Such choice double varieties as the French Chrysanthemum-flowered and the ordinary Double French, as well as numerous choice varieties, ought to be planted as much as possible where they will not be disturbed. They are very suitable for associating with alpine plants in prominent positions, and they are also very serviceable when extensively grown in fruit borders. All merit a rich loamy soil, and if the tubers are planted not less than 3 inches deep and about 9 inches apart each way, they will gradually cover the whole of the ground. Single patches may also be planted and not again disturbed. The tuberous Anemones are all very beautiful in a cut state, and are frequently available when other flowers are scarce.

ALSTROEMERIAS.

It is useless to plant these in cold damp positions; they succeed best in the comparatively hot and dry borders at the foot of sunny dwelling-house walls. They also thrive admirably on poor well-drained borders, where they spread and flower abundantly. It is necessary to plant them not less than 8 inches deep, and if the position prove favourable—that is to say, is sufficiently dry, no further pains need be taken with them. Simply let them alone.

CHIONODOXA LUCILÆ.

This charming bulb is more popularly known as the Glory of the Snow, and is closely allied to the Scilla family. Home-grown bulbs are the best, and these may be planted in patches along the front of mixed borders, and are especially attractive among low rockwork plants. No special soil is needed, and they should be planted 4 inches deep and that distance apart, and not to be disturbed for many years.

CROCUSES.

These are suitable for the front lines of flower beds or for mixed borders. If put out 4 inches deep and 3 inches apart in fairly rich soil and not disturbed for several years the bulbs increase rapidly, gradually finding their way nearer to the surface, and every spring present a grand mass of colour. They also succeed fairly well when lifted after the leaves have died, being returned to the ground in the autumn.

CYCLAMEN.

The *Europæum* and *Coum* varieties are fairly hardy, but as a rule they are most effective when treated as alpine plants, sheltered rockwork better suiting them than damp and cold flower beds. When in good health both the foliage and flowers are beautiful. Plenty of sharp sand should be mixed with the peaty soil intended for their reception, and a rather shady position best suits them.

ERYTHRONIUM OR DOG'S-TOOTH VIOLET.

This little gem ought to be permanently planted in peaty soil, or in a mixture of fresh loam and leaf soil. They ought to be planted rather thickly, and not less than 2 inches deep, along the fronts of mixed borders, beds, or shrubberies, where they will spread, first the flowers and then the foliage being attractive.

FRITILLARIAS.

The Imperial section are tall growers, and their proper place is near the back of mixed borders. The varieties of *F. Meleagris* attain a height of 1½ foot, and *F. præcox* is still more dwarf. A deep rich soil and rather shady position suits them. They are best moved with a little soil about the bulbs, and if about six of these are grouped together a fine mass results in the course of a few years.

HYACINTHS.

These are fine for either flower beds or mixed borders, no class of bulbs being more showy early in the spring. They are most effective when massed in mixed colours, and clumps of one colour are also attractive. A deep and fairly rich loamy soil suits them, and they ought to be covered with 4 inches of soil. If dotted among carpeting plants they may be placed out 12 inches apart, but if massed they ought to be about 8 inches apart each way. The Grape, Feather, and Musk Hyacinths are most effective in clumps along the fronts of mixed borders and ought not often to be disturbed. All are very pretty and worthy of cultivation.

IRISES.

The bulbous rooted Irises are very beautiful, and are suitable either for beds or borders. If planted in patches of about five bulbs and duly marked either winter or summer bedding plants may carpet the ground, and the Irises will be improved by being undisturbed. They require a good loamy soil, and should be planted 4 inches below the surface. The English varieties are the earliest, and the Spanish form a good succession.

NARCISSI AND DAFFODILS.

The choicest of these ought to be planted in patches of three or more bulbs where they will not be disturbed for some time, and every season the clumps will improve in value. Plant not less than 4 inches deep in fairly good soil. Those bedded out may be treated similarly to the Hyacinths.

TULIPS.

The sooner these are planted the better. They require to be treated similarly to Hyacinths, but should be planted more thickly, or from 4 inches to 6 inches apart, according to the variety, the Van Thols being the smallest.

VARIOUS BULBS.

Snowdrops, Leucojums, Scillas, Zephyranthes candida, Winter Aconite, and Triteleia uniflora to be treated similarly to Crocuses, patches in front rows of shrubberies and flower borders being very effective. Snowdrops succeeded admirably planted on lawns, where they spread rapidly. Ornithogalum arabicum should be planted in a sheltered spot, Jonquils treated somewhat similarly to Narcissi, and Hyacinthus candicans be planted in mixed borders and not disturbed. Tigridias to be kept out of the ground till the spring unless a warm dry position can be assigned it. Plant Ranunculus in November and December, and Liliums candidum, auran-

tiacum, and tigrinum at once in good well worked soil, and do not disturb them for several years. Freesias, Ixias, and Sparaxis are suitable for pot culture only.—CULTIVATOR.

PEACH CULTURE.

In your issue of the 11th inst. you publish a paper by that authority, Mr. T. F. Rivers, on the Peach, and all who are engaged in Peach culture will esteem the valuable information given, but in two sentences I received the impression that the author cast a douche of cold water on the practice of growing Peaches on the open wall.

I admit that where capital can be spent for houses it will prove the most satisfactory. The paper was addressed more to the trade than to private gardens I presume, in its spirit at least, but knowing that many are influenced who may not have sufficient practical knowledge, I would like to say a word in favour of the Peach on the open wall.

Here we have more than 350 feet length of wall, 12 to 14 feet high, covered with Peach trees, and there is no intention of reducing their number. Even in this exceptionally cold season the trees have produced a full crop of useful, but not large, well coloured fruits of good flavour, which have been in constant demand at the table up to this 23rd of October, when the last of the mid-season varieties were gathered. Dr. Hogg is a fine variety with dark green leaves, vigorous, free-bearing, with dark coloured fruits. Royal George is one of the best in every respect; Bellegarde, rather earlier than the above but not so fruitful. Stirling Castle is the largest named, but not so fruitful as the two first. One tree, more than fifty years old, has produced about 200 fruits and did the same last year.

The earliest varieties are not grown here, as the fruit would be ripe before wanted. The latest varieties will not ripen this year, and never do thoroughly, but we grow some of them, as I find Peaches can be grown with more certainty here than almost any other wall fruit, except Apricots, which seldom fail. Sea Eagle is a great bearer in a young state, but should be in a house to finish it; also Prince of Wales, but it is only second rate in flavour.

A portion of the border has been cropped ten months in the year for ten years up to 2½ feet from the wall, and yet gives good crops with heavy manuring. The largest portion of the border is covered with grass within a foot of the wall and 6 feet from it, but we could produce finer fruits if neither crops nor grass were on the borders 8 feet from the wall. I am convinced that large borders are not necessary for growing Peaches. We have a dry bottom on sand and gravel, altitude 180 to 200 feet three miles from the North Sea; mildew is unknown on the Peach trees; large quantities of liquid manure from the midden and guano and soot are applied. Half the wall is protected in the spring with double fishing net when the trees begin to bloom, and kept on to the 20th of May, and for greater security against frost a flued portion is covered with frigi domo in the shape of curtains, and withdrawn by day; but in ordinary seasons the net protection is equal to the latter. Under the above we do not experience blister in the leaves in spring.

A considerable amount of labour is necessary to keep the trees in a healthy condition, especially in the spring, before the fruit is fairly set, so that water can be freely applied. This is a critical time where many trees are ruined. I have often found that the longest is the best way in dealing with that pest the green fly, by washing the young shoots with tobacco liquor or other insecticide with the hand. Cold water must be applied during the summer frequently to keep down insects, and the trees and wall should have a thorough washing with strong insecticide after the leaves have fallen. Rivers' Orange and Pine Apple Nectarines colour beautifully, but Elruge is not sufficiently fruitful. Lord Napier is on trial.—GEORGE HARRIS, *Alwicks Castle Gardens*.

NOTES FROM A HERTS GARDEN.

NOTHING except the uncleared, blackened, or dried remnants remain of summer vegetables. Peas, Dwarf and Runner Beans, with Vegetable Marrows, all tender plants succumbed to the early October frosts. There is not, however, as last year, scarcity of winter edibles. Michaelmas Cauliflower—viz., Walcheren and Veitch's Autumn Giant, are particularly good, and Snow's Winter Broccoli is just beginning to "button." Gilbert's Universal Savoy, which has the quality of spring Cabbage and the flavour of Savoy with a "smack" of Cauliflower thrown in, is superb for table or any purpose, and Drumhead Savoy is valued for size and quality. We have as usual a good batch of Cabbage sprouts. The spring or early summer-cut plants allowed to remain branch and form little Cabbages for late summer and autumn use,

besides a quantity of Coleworts. I like to retain some of Ellam's Early Dwarf and Hill's Incomparable of the late autumn or early spring planting for this purpose, as they form heads better the larger sorts. There is, of course, a large breadth of Brussels Sprouts, Exhibition for early use and Paragon, both of Veitch's strain, the first having large heads and the other small, so that quantity and quality tastes are met. Then there are Spinach and roots, which last of all sorts are plentiful and good. Of Celery Sandringham and Early Rose are fine, the former short and thick, the latter twice as long and large—an excellent sort, an early form of Major Clarke's Solid Red with all its good properties, a shy "bolter;" indeed, we have not found one out of some hundred plants of a sowing made early in February, but most unaccountably some of Sandringham have gone astray. Generalities, however, have nothing of special interest, therefore I will particularise.

VEGETABLE MARROWS.—Young small Marrows, about the size of a tennis-ball, under rather than over, are in daily request, a dozen or more at a time, which I have not found any other variety meet so well as Pen-y-byd. This year we have a plant, a natural hybrid perhaps, between it and Moore's Cream, sturdier and hardier, the female Pen-y-byd, with fruits quite as numerous, swelling to double the size in half the time, the male Moore's Cream. Short-jointed Long White resisted the cold and wet well, and when put to straits we substituted it for the small sorts, with the result that it took immensely. Custard did not fruit, and Moore's Cream was most unsatisfactory.

TOMATOES.—Last year, and in most years previously, we had so many fruits from unheated houses and outdoors that we resolved not to waste a heated house over them after June, as we had a supply fully ten months out of the twelve, and much as Tomatoes and Cucumbers at dead winter are talked and written about we never had a house of either that paid a fraction of the "candle." Now we are content to insert cuttings in 4-inch pots in September, strike in heat, and keep close to the glass in a house with a temperature of 55° to 65°, with advance of 10° to 15° from sun heat. We shift the plants into 10-inch pots in December or early January, crocked, a little rough compost is placed over them, and then the plants, one in each pot, placing soil around, rough stuff, with a sprinkling of soot to take off the sickly colour Tomato plants are apt to assume in winter. They are stood at the sides of a small span-roof about 18 inches apart, and are starved—i.e., the atmosphere is kept rather dry, water given only to prevent flagging, and not top-dressed until the first trusses flower. Then soil is added with a little more soot and some manure, and they are no further trouble. Of course, the plants have all laterals removed, the leaflets shortened back, as we want fruit not leaves, and give water as required. We have ripe fruit in April. They fruit until those from seed sown early in the year and treated similarly take up the running and continue it until the others planted out in unheated houses come in, when we clear out and plant with late Melons. The plants in cool houses have grown strongly and fruited insignificantly. They are a failure. Happily we had outdoor plants. We grow Hackwood Park, Acme, Excelsior, and Surpasse. A notable feature of these plants was their extreme vigour. I never saw such stems, leaves, and trusses, the latter resembled ropes of Onions—i.e., those that set fruit. The difficulty was the cold dull weather that prevailed in June, July, and August. The leaves were remarkably fleshy, and as the plants were not allowed to produce laterals they pushed viviparous plants from the upper surface at the joints of the foliage, several on a leaf.

Ridge Cucumbers failed to fruit, though we specially threw some Oak and Beech leaves into a ridge quite 20 yards long, 6 yards wide, and 2 yards high for their particular benefit.

BEANS.—Broad Beans did well; Early Mazagan, as usual, stood best, and came in soonest. The small Beans always meet acceptance, whatever may be said of this Bean in other respects. There was unusual luxuriance in the Longpod and Windsor section, and they corned well Veitch's Improved Longpod proved a long way ahead of those in the Longpod section, it being remarkably prolific, and quite as early as the Early Longpod. Improved Windsor is large and fine, none better of its class.

Dwarf or French Beans make a sorry growth. It looked in June as if there were to be no pods, but they came after all by mid-July. Ne Plus Ultra cropped famously; it is the sort both for indoors and outdoors where but one kind is wanted, indeed it has no equal for productiveness and quality. It is also early. As variety tells for something, Negro Mammoth Longpodded may be named as excellent, also Canadian Wonder, both being very prolific and good for general crop.

Of Runner Beans we only had Scarlet Champion, as the giants and Mammoths must, if they are used at all, be sent in small, for cooks have

prejudices as well as other folk. We, however, had a 20 yards row of Chelsea Giant White, which produced truly gigantic pods, thick, fleshy, and best of all of capital table quality. The enormous size of the handsome pods render them very striking on the plant, and still more so when selected for exhibition. I have a fancy for trying things differently at every opportunity, and this year the Runner rows were placed exactly where the Celery rows had been the year before. There were others on ground we manured and dug. Comparison of the two is out of the question, suffice it we had more than double the crop on the well stirred soil of the past Celery trenches as on the dug ground, though we mulched both so as to give an equal chance. Then we had staked and unstaked rows, with the result that for one of the unstaked we have four of the staked—*i.e.*, pods, dishes, or pecks, whichever way it may be put.

ASPARAGUS.—Our soil is strong with a clay subsoil, which is not suitable for Asparagus. Still we have some fairly good beds, and have some better covering on the ridge system, but then it does no more in two seasons than I have had it do in one on sandy soil, deep and rich. To make Asparagus thrive in heavy soil, I find nothing better than the rubbish heap *débris*, with the woody portion charred, the potting bench refuse, including corks, helping to make the soil more porous, and leaf soil a foot thick worked in does wonders. Yet it costs more to make the land than will ever be seen again in profit of Asparagus. Growing for home consumption is "a leaf out of another book."

CAULIFLOWERS.—Only twice have I sown Autumn Giant in August, and had a very large per-centage of blind plants each time. They were blind (*i.e.*, lost their centres of growing point) in the frame into which they were pricked, and when transplanted in spring to the flowering quarter many more followed suit. From a spring sowing out of the same packet of seed not one in a hundred was blind, but of the August sown fully 50 per cent. went wrong. I don't pretend to be capable of giving an explanation, but it is clear it does not like checks. Nor am I going to complain, as Autumn Giant is the best of all Cauliflowers for autumn use, not autumn sowing. There is another reason. Out of the blind ones I had a plant that made ample amends by the shortness of its stem, the sturdiness of its habit, the distinctness of its leaves, and the size of its head. Believing in selection, I had it lifted and potted, and it is now going to flower in good earnest. Cauliflowers have been and are first rate. Erfurt Mammoth, Early London, and Walcheren are our sorts for autumn sowing, and for spring also, Walcheren being still a splendid all-round sort, surpassed by none except Veitch's Pearl, which is a great improvement on this popular variety, and from which it is very distinct, with quality of the finest. Grubs at the root and caterpillars have not troubled Cauliflowers, or indeed any of the Brassicas this season.

CABBAGES.—July twelvemonth I sowed Veitch's Earliest of All with Ellam's Early Spring, planted at equal breadth, with the result that Earliest of All nearly all bolted, but not one of Ellam's. It was difficult to tell which feeling was ascendant, that of mortification at Earliest of All, or the satisfaction that it was nowhere beside my favourite Ellam's, the best of all spring Cabbage. The reason I have not mentioned it sooner was through my finding the vendors did not put it forward as a spring but as a summer Cabbage, otherwise my pen was ready dipped in poison for the onslaught, and I do not care for summer Cabbages. Hill's Incomparable follows Ellam's, and they are thoroughly reliable and well flavoured as summer Cabbages, which surpass Nonpareil Improved. Of course I have not seen Earliest of All, which may be first rate in its proper season, that certainly not being its characteristic for spring use, besides it is too tender, being much cut by frost, but then I took particular pains with it—*viz.*, gave the ground a good dressing of fowl manure, had splendid plants, which were cut off by frost, and what remained our poultryman had for the fowls.—**UTILITARIAN.**

CANKER IN FRUIT TREES.

I HAVE read with interest Mr. Tonks' paper on the above subject, especially as I have for some time been of opinion that canker is due to lack of some needed plant food in the soil, or to a superabundance of some injurious mineral, as I mentioned in the *Journal*, vol. ii, p. 588, when there was a discussion on the same subject. I think if we were all to contribute what we know on this question we should sooner arrive at an answer to it, and find out exactly what is needed.

I hardly think it can be necessary to supply as a remedy all the ingredients mentioned in Mr. Tonks' formula, because many varieties of fruit trees on my soil are subject to canker, and yet we have sufficient of all he names except soda, and therefore I am

inclined to think that if any mineral is required it is this, and it can be supplied very cheaply by an annual dressing of 2 cwt. of salt per acre.

Dr. Voelcker's analysis of my soil, before applying a large quantity of dung, which I had subsequently done, shows that it contains:—

Oxide of Iron.	Carbonate of Lime.	Sulphate of Lime.	Magnesia.	Soda.	Potash.	Phosphoric Acid.	Organic Matter.
3.38	3.91	0.26	0.67	0.07	0.51	0.24	3.64

He remarks that the soil contains a considerable proportion of lime, and will not need an application of this at all, and the quantities of phosphoric acid and potash are also fully up to the average of good fruit-growing sorts.

As the fruit of the Apple contains a large proportion of soda, and our soil contains a great deficiency of this, and has sufficient of other minerals, it points to the conclusion that if canker is due to the lack of any particular mineral, in all probability it is soda that is required, besides keeping up the general fertility of the soil by means of dung or other fertiliser. The fruit of the Strawberry also contains a large amount of soda. I have grown a large quantity of Strawberries for market, and my neighbours have told me that the fruit has been exceptionally fine, and have been surprised at my crop compared with theirs. I believe it is largely due to supplying the plants with soda, besides nitrogen and phosphoric acid by means of bone dust. I see Mr. Tonks mentions superphosphate in his formula. For my part I do not like to put superphosphate on the ground because of the acid it contains, and I use bone dust instead.

Mr. Tonks thinks it is wise to apply iron in case it is required. The quantity of iron present in our soil I think disproves this, and indeed I suspect iron is a cause of canker, for the more the subsoil here is red with iron, the more the trees suffer from canker, and I apply such manures as I think tend to dissolve this iron.

Very likely if trees have a sufficiency of soda and other necessary minerals they might be able to withstand the iron. I hope other contributors will give their experience.—**WALTER KRUSE, Maidstone.**

I READ with much interest the valuable paper on canker by Mr. Tonks reproduced in last week's *Journal*, the conclusion he arrives at being that the secret of the matter lies in some deficiency of the mineral elements the soil should contain to enable the trees to grow healthily and vigorously. It is very noticeable that this gentleman makes no reference to the relation of acari to this malady, on which Mr. Hiam and others have laid so much stress. As you may remember, though I could not accept the view that an attack of acari originated the canker complaint, I was fully convinced by observation that the insects often seriously aggravated the mischief, hence the advisableness of dealing with them. I think it is in evidence that certain varieties—of the Apple obviously, probably also of the Pear—are specially liable to canker. I do not know in what relation this fact stands to Mr. Tonks' theory.

During the year 1884, and 1885 also, I think, you had complaints concerning a large aphid of a black hue, which infested *Chrysanthemums* in some districts, and which, if rarely numerous enough to prevent flowering, was decidedly a source of harm to the plants. Have you heard of any recent appearances of this? It was presumed to be exotic, and therefore might die out, particularly as, like others of the aphid group, it would very likely migrate in spring or autumn, and might fail to find a change of food suitable to its habits were it a foreigner.—**J. R. S. C.**

ROMAN HYACINTHS.

IN my opinion Roman Hyacinths are not so much grown as they merit, more especially for flowering at Christmas. Those who grow many *Chrysanthemums* may find them attractive in November and the early part of December, but by the middle of the latter month their beauty has departed. Such pure fragrant flowers as those of the Roman Hyacinth are then simply invaluable. We have tried to force many bulbs into flower at that time and failed, and I hold that all who have only moderate means of forcing will be unable, as a rule, to flower any of them by Christmas excepting the Roman Hyacinth. With it, however, there is no difficulty, and this is why it should be forced more generally than any other; indeed it flowers so freely about midwinter as hardly to deserve being termed a forced plant, and no one ought to have the idea that it is expensive to secure it in bloom when the bulbs are potted in October. If kept under ashes the greater part of November, or until the growths have become 2 inches or so in length, it is afterwards a difficult matter to prevent it flowering. We require our earliest flowers of it about the middle of December, and the

last about the middle of January, and we are afraid to pot the last bulbs until the middle of November, as by merely keeping them in a temperature that excludes frost it is a difficult matter to prevent them flowering before they are wanted. One year we purchased cheap bulbs and thought we had secured a bargain, but many of them failed to produce a flower. Since then we have had the best obtainable, and the majority of them produce two, and many of them three spikes.

The largest flowering Hyacinths have a fine appearance when potted singly in 5 or 6-inch pots, but the small Romans are not so massive, and single plants do not look well even in small pots. They appear best in little groups, and if six or eight bulbs are placed in a 6 or 7-inch pot they will give much satisfaction. We find them grow most freely in a somewhat light rich soil. The pot is drained and filled with soil, and then the bulbs are pushed into it, the soil being pressed hard down afterwards, and only the crowns are visible when potting is completed. They are then placed as close as they will stand in a cold frame, and are covered with ashes to the depth of 8 or 10 inches. The lights are arranged over them to prevent the soil being saturated with rain, and they are left undisturbed for three or four weeks. At the end of that time it is always found that the roots have penetrated the soil freely and the tops have attained a height of several inches, then they are ready for taking from the ashes and placing in a temperature of 60° or a little more to induce them to flower. If one, two, or three hundred are potted and plunged at once, and only half this number are required to form the first, place those not immediately forced in a cold frame, and keep them there for a fortnight or so, when if placed in a little more heat they will succeed the others. As the tops expand more water is required, but the spikes do not require staking, and by the time they are in flower they will be surrounded by a quantity of green foliage, which has a very cheerful appearance. Once in flower they may be placed in the greenhouse or conservatory or out for the rooms.—M. M.

GRAPES SCALDING.

Mr. RIDING, at page 333, appeared to consider that the ideas I advanced on this subject are mere theory, but I can assure him such is not the case. My ideas are entirely based upon facts and close personal observations, and I can give him a case in point. Upon taking charge of a garden a few years back in the month of November, I found a quantity of whiting remaining on the vineries, three in number, and I was informed it was used to prevent scalding. The two earliest houses were constructed of iron rafters and copper bars, with sliding lights, but each alternate light was fixed, so that only half of them opened at the top. The varieties of Grapes in the earliest house were Black Hamburgh and Buckland Sweetwater, in the second house Muscats chiefly, also in the late house which was constructed of wood for rafters and bars, with continuous opening lights top and bottom; the two early houses had also continuous opening lights in front]. The varieties were eight of the most popular late Grapes, including three Vines of Lady Downe's at the warmest end, and I was informed that they were all scalded more or less; but the Lady Downe's Vine at the end (west) was the one that suffered most, more than its two neighbours, and I had ocular proof of the fact; but the other varieties were not so conspicuous in that respect, the Muscat of Alexandria next to the Lady Downe's appeared to be the worst. The following season, as the Vines came on in succession, the precautions given on page 294 were faithfully carried out by the young man in charge, and the early house, which was started in January, escaped without any artificial shading, but in the Muscat house, which was started a month later, a few berries were touched, as at the time of stoning I remember it being extremely hot, and with all the ventilators and doors open the temperature was more than I desired; but that was the only season they did scald while I was there, and the late house being better constructed as regards ventilation, escaped without any of the bunches being damaged by scalding. Previous to taking charge of these gardens, I had charge of some vineries where Lady Downe's was grown, and scalding was not seen there; and I know of other places where scalding is scarcely seen, and the ventilation has been attended with the greatest care in these cases. I advocated the practice that has done me good service, and I am at a loss to understand the same practice failing with others.

In advocating fixed temperatures for the guidance of those in charge, I did not consider it necessary to add that due allowance should be made to meet exceptional circumstances, as I considered that is generally understood, as I am fully aware that it is neither necessary nor desirable that the temperature should be so exact. Though these fixed temperatures are so much condemned by your correspondents, in what way are we to communicate to the inexperienced young men the temperature desired in the various compartments under their charge better than having them attached to the thermometers? The system is carried out in some of our best establishments, both private and public. The system in itself is right enough; it is its abuse that leads to bad results, as in many other good customs. The rational system advocated by some of your correspondents may be successful in the hands of experienced men, but I consider dangerous in a high degree with the inexperienced, and likely to lead to carelessness. I am fully aware

that there are many ways and means of attaining the same end, and let each individual adhere to those he finds the most successful, but when success does not accompany our efforts, it is then time to seek a change to remedy the evil. I did intend writing more fully on the subject of scalding, but Mr. Coombe I consider has treated it more successfully than perhaps I could.—W. SIMPSON.

SATYRIUM CARNEUM.

Few members of the genus *Satyrion* are grown in collections of Orchids, yet they are interesting and in some cases beautiful.

FIG. 46.—SATYRIUM CARNEUM.

They are somewhat difficult to manage successfully, but with a little careful attention their peculiarities are soon ascertained. Cool houses or cold frames suit them best, for, like most of the terrestrial Orchids from temperate climates, they are impatient of excessive heat or undue exposure to the sun when in growth. A compost of light loam, peat, sand, and leaf soil generally gives the best results, supplying water with great care. *S. carneum* was recently shown by Mr. T. S. Ware of Tottenham before the Floral Committee of the Royal Horticultural Society, when a first class certificate was awarded for it. The flowers are borne in a stout

spike with imbricating leaves and bracts, as shown in fig. 46, the colour being a soft blush or pinkish hue. *S. aureum* is one of the finest of the genus, the flowers large, rich orange, occasionally shaded with crimson. The last named plant has been successfully grown by Mr. Wildsmith at Heckfield.

SOPHRONITIS GRANDIFLORA.

THIS bright Orchid is flowering well at the present time in the gardens of Chios House, Clapham Park, and this charming Orchid is one of many that are well grown by Mr. W. Collins, well known as the Secretary of the United Horticultural Benefit and Provident Society. That Mr. Collins' zeal on behalf of the Society does not cause him to neglect his professional duties is evident from the condition of the plants under his charge, a somewhat extensive collection, testifying by their healthy appearance to his skill as a cultivator.

CYPRIPEDIUM ELLIOTTIANUM.

A NEW *Cypripedium* has recently been imported from the Philippine Islands, and has received the above name. A flower which expanded on the plants while in the cases has been forwarded to us with a leaf. It is evidently a strong grower, and is said to be very free, having been found with five flowers on a spike. The flower sent reminds us of *C. Stonei* in shape, the lip veined and flushed with rosy purple, the dorsal sepals white with strongly marked longitudinal deep purplish crimson lines, the petals narrow, drooping, and dotted with a similar colour to the lip on a white ground. The flower in question is no doubt much below its full size, but it is $3\frac{1}{2}$ inches in depth from tip to tip of the sepals, and the petals are about the same length each.

ORCHID PROTECTOR.

ENCLOSED please find model of a contrivance for protecting the young growths of *Lapagerias*, Orchids, &c., from the attacks of slugs, mice, woodlice, &c. As you will see, the protector is made so that the growth to be protected comes through the central tube, the space between the tube and outer rim being filled with water or chemicals distasteful to slugs and other vermin. It is made in various sizes, and we intend to have it made in pottery ware from about 3 to 5½ inches in diameter. We have it in zinc with three prongs at the bottom to fix it firmly in the soil. It is the invention of H. R. Bridson, Esq., and is provisionally patented. Will you kindly give me, through the Journal, your opinion of it, whether there is likely to be a demand for it sufficiently large to make it worth while to complete the patent and advertise it in the gardening papers? At present I am unable to say at what price it will be sold.—T. ARROWSMITH.

[The contrivance appears to be a simple and useful one that could no doubt be produced at a cheap price, and in that case would probably command a ready sale if well advertised. It consists of a funnel into which is soldered a cylinder at the lower end, thus leaving a space to be filled by a liquid between the expanded portion of the funnel and the cylinder. There might in some instances be a little difficulty in fixing it over Orchid spikes, but the three prongs mentioned would facilitate this considerably.]

ORCHID FLOWER HOLDER.

MR. ALFRED OUTRAM, 7, Moore Park Road, Fulham, sends us a specimen of a contrivance for holding Orchid flowers when cut from the plants, a patented invention by Captain Maxwell, Terregles, Dumfries. Mr. Outram observes, "It is a fact well known to all Orchid growers that valuable plants are frequently much reduced in vigour and health through their flowers being left on them too long after they have reached maturity. The object of this simple contrivance is to enable growers to relieve their plants by cutting off the spikes, putting them in the tubes filled with water, and inserting the flower-holder in a natural position in the pots. The wire being pliable, the tubes can be placed in any convenient position, so that a natural effect can be gained by showing the spikes in conjunction with the plants, at the same time relieving the latter of the heavy strain upon them. Floral decorators will find the Orchid Flower-holder most useful, inasmuch as being made of any length it will enable them to arrange for the distribution of flowers in positions that without it cannot now be utilised." The holder consists of a simple narrow cylinder, closed at the lower end, and fixed to the upper portion of a stout wire, which can be inserted in a pot in any desired position.

PLANTING FLOWER BEDS FOR SPRING.

I NOTICE in the Journal of October 11th a few words on this subject by Mr. Ward, and now is the time when the subject should be brought prominently forward, for our ordinary summer gardening has this season been very unsatisfactory. The best bed I had amongst others was one of a silver-leaf *Pelargonium* and *Viola Countess of Kintore*, and I have

seen how well *Violas* have flowered in Mr. Dean's nursery at Solihull, which is near to our gardens, so that I have determined to use them more extensively another year. I know also that Mr. Brown at Elmdon Hall, one of the best known gardens in the Birmingham district, intends discontinuing to some extent the usual bedding plants and using *Violas* much more than he has done. *Violas* work in so well with Tulips, Narcissus, and other plants, and with these bulbs keep up a succession of bloom from the end of March to as late as wanted—that is for spring bedding; then the *Violas* can be taken up in June, cut back, and laid in on a shady border for autumn. *Violas* for planting in May and June should be removed with balls of wet earth or from pots, but as I have grown *Violas* now as decorative plants for a few years, I strongly advise planting in October or November for a spring and summer display. The selection I have made this year for adding to mine are:—In yellows, Golden Prince Improved is the best and most lasting deep yellow, and Ardwell Gem, pale yellow, and both of a dwarf compact habit. In whites, Countess of Hopetown supersedes so many others, dwarf and compact, of good constitution, and a wonderful bloomer; and Mrs. Grey is a very free bloomer, but is tinted with lilac in hot weather, but it has the merit of being very sweet scented. In blues nothing equals Dean's True Blue, perfect in habit and an excellent bloomer. Queen of Lilacs and Archie Grant are two other first rate varieties. Holyrood was always a favourite with me, and it has done well this year. There are others of great merit, and many of the new ones of great beauty. Elegans, for instance, a pretty lavender, and makes rather long growth, but is a great bloomer, and fine mixed with yellow *Calceolarias* or white variegated *Pelargoniums*. I have seen the *Violas* about here, masses of flower which the continued wet weather did not seriously affect, whilst beds of *Pelargoniums*, &c., had a sad washed-out appearance. The *Violas* were bright, for although heavy rains caused a little hanging of their heads, an hour's sunshine brightened them again. I find, however, that the flowers of the purple varieties will not stand so much wet as the others do, but damp off, and I find that of the purples Unique did the best. The *Auhrietia* I find to be most useful for spring work, and the *Silene* where it will stand, but in the midlands I find a difficulty in keeping it from damping unless in a mild dry time.—W. C.

NOTES ON PLANTING.

THE time has now arrived when rosarians should be busy in making arrangements for planting, for forming new beds, ordering new Roses, and moving plants of their own. November is generally considered the best month for planting, but probably a good many plants, all those which have ceased to grow, might now be moved with safety; and the sooner the better, as the fact that Roses do make fresh roots during the winter months was, if I recollect right, fairly established in the Journal some years ago. Any time during the winter will do for planting when the weather is open and fairly dry, though that combination is not always easy to find after Christmas; in fact, in the disastrous year of 1879 I successfully moved some outdoor standard Roses from a place two or three counties away on May 10th, and they grew and did well. Still, it is best to plant early, not only for the sake of the well-doing of the plants, but also because we have now a better chance of obtaining good plants from the nurseries than when their stores are running low. And on this subject I am glad to think that amateurs may congratulate one another upon the fact that Roses are now "cheaper than ever."

The main points in Rose-planting are pretty generally understood, and need not be enlarged on. They are:—Do not unpack in severe frost; lay in the roots, and perhaps wet the tops till the actual time of planting; never expose the roots to the air longer than necessary; have some fine fairly dry soil under cover to place against the roots if your soil is very heavy, or if you are obliged to plant at a wet time; do not plant deeply, but with dwarf huddled plants just bury the union of stock and scion; cut cleanly off all bruised portions of roots before planting; let all the manure you use be well rotted, and let none of it actually touch the roots; plant firmly, carefully, and evenly.

All these points are to be found mentioned in any work on Roses or calendar of operations; but in the excellent instructions issued with Mr. Frank Cant's catalogue I find two points which are not often alluded to. The first relates to Rose plants, which, owing to delay in transit, arrive in a shrivelled state. I cannot answer for the treatment recommended, but can quite believe that it would be effectual. It is simply to bury them completely, roots, tops, and leaves, about 6 inches deep for three days, soaking the whole, when buried, thoroughly with water. I have never had occasion to try this myself. There must be, I should think, very unreasonable delay in carriage, or considerable want of care in packing, to cause sound wood to arrive in a shrivelled state anywhere within the British Isles; but I imagine it might well happen with exported or imported plants, and if anyone on receiving Roses in such a state should be inclined to throw them away it would be well to remember and try this plan.

The second point is the arrangement of the roots in planting. This

is very important, and indeed is the very essence itself of successful planting. Each root should be laid out separately and carefully; and in doing this remember that the bark, so to speak, of the roots is easily rubbed off, and any such wound causes injury. In handling each root "use him as if you loved him," as old Isaac Walton said of the worm as he passed the fish-hook through him. Share the whole room at disposal equally and fairly among the roots, keeping them from touching each other. If it seems impossible to prevent their crossing raise one and lower the other, and put some fine soil between them. If circumstances compel you to fit the roots to the place instead of the place to the roots choose rather to cut a root off cleanly than to coil it round. We will not now raise again the question of last year as to whether it is desirable or not to retain the tap roots of Roses worked on the Briar seedling; but remember that the minutes spent in planting are all-important to the spring growth, and that it is little use wasting much time in careful pruning of the branches in March if the roots are packed in anyhow in November. A careful amateur, even if he is unable to assist in it himself, will not delegate the work of planting in his absence to anyone whom he has not carefully proved by experience. And, lastly, remember that it is very difficult for one man to manage anything but the smallest plants alone; and in all cases two men will do the work quicker and much more efficiently.

I always move a few newly budded stocks every year. Care in planting is everything in this case, and a certain proportion will do as well as if they had not been moved. In April, 1887, I found a budded Briar cutting in a secluded part of the garden which had been accidentally dropped the November before, and had lain on the ground all the winter; it did fairly well on being planted carefully. I rescued another from the rubbish heap last winter, just in time to prevent its being burnt, and that, too, made fair growth; but, as a rule, it is better to leave the budded stocks where they are, if possible, for one year.

Now is the time also to prepare Briar cuttings for striking; a far larger proportion will grow, if put in now, than if inserted later. Make the cuttings about 10 inches long; be very careful to cut out all the eyes except the two top ones. Choose well-ripened small wood in preference to sappy thick shoots, and insert them up to the bottom bud in not too heavy soil. It must be a clean piece of soil, too, or the cuttings must be set well apart, for it is a difficult crop to keep free from weeds. If exposed to a severe winter it will be well to go over them in the spring, and push down again to the bottom of their holes any which have been raised by the frost.

The severe frosts which we have already had have cut off all our tender flowers, and at the same time I am glad to say have put a stop to the earwigs for this season. From the end of May to October 1st we destroyed on an average 400 a day, but they completely disappeared with the first frost, and the only one I have seen since was a lively specimen which arrived by post last week inside my copy of the Journal, so there are some in Fleet Street still.

ROSE STOCKS.

I do not think "Duckwing" would find any of the H.P. Roses better than the common Briar as stocks. The advantage of the latter is that, either as cutting or seedling, it forms very strong roots the second year, which the H.P. Roses do not do by themselves. It would not be much in favour of John Hopper as a stock that it does not generally make base shoots, for it certainly would, when cut back after budding, if the eyes had not been originally taken out. Some of the Gloire de Dijon race of Teas form pretty good stocks for strong-growing Teas or for Maréchal Niel. I have now a capital strong plant of William A. Richardson, which I budded on a cutting of Madame Berard. It seems a fair question as to whether Tea Roses should still be allowed to be shown among the H.P.'s. Personally I should much deprecate their exclusion; and it must be remembered we have as yet no yellow H.P.

It is well known that what Mr. Murphy calls "manufacturing yearly Roses" is a process almost necessary for exhibitors, because some of the best Show varieties are seldom found to perfection except on yearling plants. This entails a double amount of space, and a fresh supply of stocks every season. Some years ago I "had an idea," as the French say, by which I hoped to obviate this necessity. Weakly sorts, and those of bad constitution, do best the year after budding, because they are so strongly supported by the abundant roots called forth by the wild top growth of the year before. They fail, comparatively speaking, the next year, because their over-weak growth, which alone has been permitted, has starved the roots and rendered them weaker. My idea was—and I only thought of standards at that time—not to bud on the top lateral, but on one below it, and in the following spring in cutting the top lateral away, not utterly to destroy it, but allow room for one wild bud at least to perish. This wild shoot to be pinched back and ripened as much as possible without actual destruction during the time of growth and flowering of the Rose; but, as soon as the two or three blooms had been taken, to be allowed to grow again as much as it liked during the rest of the year. I fancied this would restore and keep up the strength of the roots. The following March the wild shoot and the Rose to be pruned back to one bud each, and the Briar shoot to be pinched back during the spring as before; and the idea was that the plants would thus, during the months of August and September, yearly renew their youth. They would not look very nice during the autumn months, but would not be worse in appearance than budded stocks usually are, and the plan was only meant for those sorts which exhibitors consider it necessary to bud each year, and which are not suited for general garden decoration, such

as Horace Vernet (especially), Harrison Weir, Louis Van Houtte, Xavier Olibo, and perhaps Monsieur Noman.

I did make a trial with a small row of standards budded with Horace Vernet, but happened to leave my then residence before the experiment was complete, and have never had any standards since. It has now, however, occurred to me that the same thing might be carried out with Briar cutting, and even with Manetti, though not very well with Briar seedling; and I mean to try it.—W. R. RAILLEM.

ROSE CULTURE.

[By Mr. T. Bones, gardener, Tower House, Chiswick, winner of first prize for an essay on some gardening subject. Prizes offered by Mrs. S. A. Lee, 4, Arlington Park Villas, Chiswick, for competition by members of the Chiswick Gardeners' Mutual Improvement Association, under the age of thirty.]

(Continued from page 390.)

FORCING.

ROSES can be had early in the year (and what is more acceptable than blooms of this charming plant in spring time?) by placing them in gentle heat. Of course, they must be previously prepared for this work, and none but well-established plants should be forced. The wood should be well ripened up by the autumn, and pruning should be done when the plants are at rest. Much time is lost if this is deferred till the buds begin to burst—not only time, but it tends to weaken the plants, because the young wood swells, and that at the base remains dormant, as one cuts away the growth that has already been made. On the other hand, if the pruning had been done early, all the energy would have gone to produce flower shoots. As soon as the plants are placed in heat they should be kept syringed and placed near the glass to get all the light and air possible. They should never know the want of water. When the buds are beginning to swell they should be supplied with stimulants. Soot water or Clay's fertiliser will be found beneficial, and may be given as required. If convenient the pots should be plunged in leaves, as this tends to keep them moist. If mildew makes its appearance give a dusting of flowers of sulphur. Green fly should be destroyed by fumigating with tobacco.

Select plants for forcing that are of a free-growing nature and dwarf habit, care being taken not to let any cutting wind come directly on the plants, as this is injurious to the young growth. As soon as the plants have done flowering, and the weather is favourable, they should be placed out of doors, and kept syringed once or twice daily. This keeps down red spider and other insects. Watering should be well attended to when making their growth; the pots may be plunged in ashes. About July the plants that require it should be repotted, but care must be taken not to overpot them. Use a compost of fibrous loam, cow manure, and a little peat or leaf soil and sand for Teas, but for Hybrid Perpetuals and all other strong-growing sorts the compost should be more of a stiff nature; pot firmly. Those that do not require potting should be top-dressed, taking off a portion of the old soil and replacing with new, making it quite firm.

SELECT LIST OF VARIETIES.

The following serviceable sorts I would recommend for general purposes—namely, Teas:—Anna Olivier, flesh colour, large; Catherine Mermet, delicate flesh colour; Devoniensis, creamy white; Gloire de Dijon, buff, orange centre; Isabella Sprunt, sulphur-yellow, very free; Niphetos, white; Perle des Jardins, deep straw colour; and Souvenir d'un Ami, salmon-rose.

Céline Forestier, bright yellow; Rêve d'Or, yellow; Maréchal Niel (everybody's favourite), bright yellow; and W. A. Richardson, deep orange-yellow, are all good Noisettes.

Abel Carrière, velvety maroon; Alfred Colomb, carmine-red; A. K. Williams (a grand sort), crimson; Beauty of Waltham, light crimson; Boule de Neige, white; Baroness Rothschild, pink; Charles Lefebvre, velvety crimson; Captain Christy, flesh colour; Dr. Andry, red; Fisher Holmes, scarlet-red; Général Jacqueminot, brilliant red; John Stuart Mill, clear red; John Hopper, rosy crimson; La France, lilac-rose; Prince Camille de Rohan, dark crimson; and Star of Waltham, bright crimson, are very select H.P.'s.

In conclusion, let me observe that whatever the would-be Rose cultivator takes in hand with regard to the national favourite flower, let it be done thoroughly, for, as Dean Hole has so well written in his delightful book on the Rose, "He who would have beautiful Roses in his garden must have beautiful Roses in his heart!"

LONDON'S LESSER OPEN SPACES—THEIR TREES AND PLANTS.

NEW SERIES.—No. 10.

No one can stroll about the districts of western London which it is the fashion to call Tyburnia and Westburnia, comprising portions of what is otherwise known as Paddington and Bayswater, without seeing many proofs in gardens and windows that the inhabitants are fond of flowers, a fact which is of advantage to the florists of the Uxbridge and Edgware Roads. Paddington is not one of those suburbs which in the olden time were notable for their gardens, orchards, and parks. The greater part of the moist meadows into which it was divided were devoted to pasturage till some fifty or sixty years ago. On its east, however, there was woodland, for St. John's Wood was not merely a name, it had a fine growth of

timber trees when it was the property of the Knights of St. John, and a few of its old Elms remained after the other trees fell before the axe. In Marylebone Park adjoining, and of greater extent, the English kings hunted deer, but this was disparked and the ground cleared, fortunately not to be covered with houses, so that eventually another park, the Regent's Park, arose, preserving this large open space as one of the lungs of London. This, however, belongs not to my present subject, and I only name it in passing, because its central ground, now the garden of the Royal Botanic Society, was formerly a much-visited nursery belonging to Mr. Jenkins, and from which were distributed many of the trees or shrubs we now see in North-west London. His nursery was noted for forced flowers, the demand being sometimes very large in the early months of the year.

Marylebone Road is one of those semi-suburban roads, which, even when the growth of streets in all directions about them is altering their neighbourhood, still manage to retain the aspect they bore during the old coaching. The houses lie back with long gardens fronting the road, shaded with occasional Planes, Poplars, and Limes, and their walls are thick with creepers, such as Clematis and Jessamine, and I observed a few covered with Vines, but they have probably ceased to bear fruit. The gardens have also many of the old-fashioned flowers and shrubs; amongst the latter I noticed sundry instances of what are not unfrequent about London, both evergreen and deciduous species which have been suffered to grow to their own liking, untouched by the shears. These bushes become a dense mass of twigs, a joy to the cockney sparrow at this season, as he can retreat within them and bid defiance to prowling cats. The burial ground of Marylebone church in this road is now open to the public, a space of about an acre; its few trees are not aged except two or three of the Elders which our ancestors loved to plant in such spots, and no attempt has been made to cultivate flowers here, but the two principal beds contain—the one Lilacs and Thuias in circles, chiefly the former arranged in circles, the other Privet bushes in rows—the effect being somewhat singular. We come upon a different scene in the Paddington Street extra ground of three acres, for this is gay with October flowers, the yellow hue predominating. A variety of Dahlias, single and double, plentiful Marigolds, appropriate to a place once dedicated to St. Mary; Eschscholtzias also, Helichrysums of two colours relieved by Phloxes, and a few late Antirrhinums. Tender perennials had been planted out singly in the borders, such as Pelargoniums and Fuchsias, but the cold nights were touching these. The older trees in the ground were Birches, Poplars, and Willows, and some twisted Hawthorns, with lines of young Planes and Limes. Altogether it is a pleasant garden, a boon to young and old in that district.

Going northward to St. John's Wood we pass Park Crescent and Park Square, private grounds for the residents, containing together about 11 acres. They are well timbered, in fact the numerous trees do not much favour the cultivation of flowers or the growth of grass, yet it would be a pity to remove any, and vacant spaces here and there in the centre are filled during summer with choice flowers, now just housed for the winter. Sunflowers had been largely sown in the spring, and within Park Crescent the long lines of these tall plants had an odd appearance. An inspection of the mode of growth of the flower-stalks when a number are looked at dispels the theory that this species has any partiality for opening its flowers towards the south. Round this Crescent there is a hedge of Hornbeam, which is not often seen in London squares, but it has not the advantages of other species planted for hedges which are thorny or of denser growth. On the west of Regent's Park, in St. John's Wood Road, are three open spaces contiguous to each other. Farthest west is the well-known cricket ground, Lord's, at one time a nursery, or part of it was at least, not now accessible to the public; next it the mansion and garden of the Clergy Orphan Asylum, and across Wellington Road is St. John's Wood Chapel burial ground, a space of seven acres, open to all. The old tombstones have been left intact, which is just as well, for had the ground been cleared of these to lay out flower beds, many of the trees must have been also removed. By these the walks are made shady yet cheerful, hence the place is much liked by quiet strollers. Doubtless the trees have each their history could we trace it out. The varieties are numerous, the largest being Scotch Elms, Willows, and Black Poplars. The Willows are, as usual *Salix alba*. It is surprising that the devouring caterpillar of the goat moth has suffered some of them to reach their present size; this insect is also an unsparing enemy to the Elm, the Scolytus beetle completing the damage begun by the caterpillar, but I think this attacks the English in preference to the Scotch species. Here are good examples of the Weeping or Babylonian Willow, of the Weeping Ash, and the Beech, a tree, however, which does not seem to flourish in London suburbs. An avenue of Horse Chestnuts still retained many of its leaves,

though a row of Limes close by was almost bare. Some remarkably fine Portugal Laurels were noticeable, and examples of the Sumach and purple Barberries, rich in leaf, near melancholy looking Guelder Roses—how fond Londoners were of this species, I suppose because it flowered early when it inclined to bloom at all, for this is of uncertain appearance in the town smoke. I am surprised the Mezereon has not had more patronage, as it does not object to the London air, and, like the *Jasminum nudiflorum*, clothes its twigs with blossoms at the dawn of spring. A few large Hollies and Box trees look as if they had been planted when the ground was first enclosed, but the Larches and Firs have been a failure, the clay soil does not suit them at all. An appearance of antiquity has been given to the chapel by Ivy planted all round the walls, which has made rapid growth and festooned itself over windows, turrets, and buttresses. The most singular tree in the ground was a Plane, which was about 20 feet high, and had thrown out branches forming circlelets one above another, unlike its wonted mode of growth.

Paddington Green, in the Harrow Road, has no trees; it is cut into four divisions by railings, and retains its grassy greenness, but flower beds have been made amongst the turf, and these are filled during the summer with bedding plants. In most cases one kind is predominant, and beds of *Calceolarias*, *Lobelias*, and *Pelargoniums* were putting forth late flowers, where they are edged with Golden Feather, this is allowed to remain, and it keeps up a semblance of green in the winter, till spring bulbs are introduced. Near to this is Paddington churchyard, of 3 acres, which offers no points of special interest. On my visit to this part of London in the middle of October an aphid migration was going on to a small extent. This would represent the customary autumn migration of winged types of these insects, but it was decidedly late. Aphides generally have been far from abundant this autumn owing to the heavy rains, the exceptions are those species that live either in circled up leaves and buds, or upon the roots of plants.—J. R. S. C.

THE SHOWS.

THE Chrysanthemum Shows commence with Southampton to-day (Thursday), to be followed next week by Kingston, on Tuesday, November 6th; the National Chrysanthemum Society at the Royal Aquarium, Westminster, on Wednesday and Thursday, November 7th and 8th; Tooting on the same days; Portsmouth on November 7th, 8th, and 9th; Teddington on Thursday, November 8th, and the Crystal Palace on Friday and Saturday, November 9th and 10th.

We are requested to state that the Bedford Chrysanthemum Show will be held on November 14th and 15th, when, as several open classes are provided, it is hoped that the metropolitan exhibitors may be induced to compete. The Hon. Secretary is Mr. J. Sanders Clarke, 49, Linden Road, Bedford.

NATIONAL CHRYSANTHEMUM SOCIETY.

A FULLY attended meeting of the Committee was held at "Anderson's Hotel," Fleet Street, E.C., on Wednesday evening last, Mr. E. Sanderson, the President, in the chair. The Eastbourne Chrysanthemum Society was affiliated, and eight new members were enrolled, bringing the total up to 581. The Hon. Secretary reported in reference to the coming provincial show at Sheffield that everything connected with it was quite favourable, and a great deal of interest has been taken in it by the inhabitants. It is hoped that one of the Ladies Fitzwilliam will attend and open the exhibition. The Hon. Secretary reported that the British Fruit Growers' Association had applied to hold a meeting at St. Stephen's Hall on the second day of the November Show—the 8th—and that the authorities at the Aquarium had consented; also that he had sold 150 copies of the new catalogue issued by the Society, that ten or twelve dozen copies were out on sale or return, and that an application had been received from Mr. E. H. Libbey of the American Garden, New York, for two dozen copies. Next came the presentation by the President to Messrs. Lewis Castle, Harman Payne, and G. Gordon, of the silver medals of the Society, voted to them for their services as revisers and editors of the new catalogue. The Hon. Secretary also reported that he had paid the sum of £52 10s. for medals applied for by affiliated societies. By way of extending the usefulness of the Society, Mr. C. Harman Payne was appointed to act as Foreign Corresponding Secretary, as a good deal of correspondence with the Society came from abroad. It was resolved that the Judges of fruit and vegetables at the November Show should examine all new vegetables sent for certificates, and award the same to those subjects deemed worthy. It was unanimously resolved that the annual dinner of the Society should take place on Saturday, December 15th, at "Anderson's Hotel." It was also resolved

that Sir Guyer Hunter, M.P. he requested to open the Exhibition at the Royal Aquarium, on Wednesday, November 7th. A cordial vote of thanks to the Chairman brought the proceedings to a close.

LADY SELBORNE.

THIS variety has again this season maintained its reputation as a capital producer of white flowers at a time when Madame Desgranges and its relatives are past, and before Elaine comes in, which is an advantage, because the plants can be cleared out to make more room for the general collection. Two plants in a 10-inch pot will produce ten or twelve good sized pure white blooms if the plants were topped when 4 inches high, afterwards selecting that number of shoots, removing all side growths and retaining one bud on each stem.

SCEUR MELANIE.

We have had abundance of flowers on dwarf plants of this variety in small pots. Plants that were topped once at 4 inches high, allowed to retain all their branches afterwards, are now 2 feet 6 inches high from the top of the pot, which need not be more than 7 inches across, are now developing a fine show of blooms of a delicate pink shade of colour which will change to pure white as they expand. The great character of this variety is the manner in which it blooms simultaneously, rendering the branches so useful for cutting with long stems without sacrificing many buds and partly unexpanded blossoms. More than this, it carries its foliage so well. This being of a deep dark colour at once renders it valuable to edge the fronts of groups. Soil of a good quality should be provided, and where pots of the size named are employed abundance of water will be needed several times a day to keep the foliage fresh and develop the blooms in the best possible manner.

TEMPERATURE FOR DEVELOPING THE BLOOMS.

Inexperienced growers of Chrysanthemums are often at a loss to know the temperature required for the plants at a time when the blooms are developing. I find there is a prevailing opinion that a fixed temperature is necessary at that time of the year. Circumstances must guide the cultivator in this, such as how the blooms are expanding according to the date at which they are required. The weather must be taken into account in admitting air to the plants. During bright sunny weather, if the plants are sufficiently forward for the date required, abundance of air should be admitted to dry the atmosphere, which is of great assistance in preventing the florets damping, causing disfigurement of the blooms, also reducing their size considerably. If wet or foggy the amount of air should be reduced and the pipes warmed. Blooms requiring this treatment should be partly expanded, say one-quarter developed if the show is in about three weeks' time. If the buds have not yet shown colour the plants must be kept closer, making use of sun heat early so as to avoid forcing the plants by fire heat later on. Chrysanthemums will bear a temperature of 60° during the night by fire heat, but a better development is effected in a temperature 10° lower if possible. In all cases where forcing the plants into bloom with fire heat is necessary a small portion of air should be admitted to the plants always; this prevents the petals damping somewhat, which is a serious hindrance to the proper development of the blooms.—E. MOLYNEUX.

CHRYSANTHEMUMS IN IRELAND.

SINCE my notes of last week I have a bad report to give of prospects of growers in this neighbourhood. The damp which made its appearance during the bright dry weather in the middle of this month increased rapidly since the present muggy weather has set in. Fine blooms, half expanded, which appear all right to-day get touched all over by to-morrow. The collections which have been best grown seem to have suffered most. It is very disheartening to see plants which have had the most careful attention since December last from the most experienced growers in Ireland now going to the bad, and apparently nothing can be done to save them. The plants looked splendid when being housed, having foliage down to the pots, and well set plump buds of great promise. Plants grown with a quantity of bloom for decoration, such as the Rundles, have escaped up to this. The varieties most affected are Ed. Audiguer, Madame Audiguer, J. Délaux, Jeanne d'Arc, Belle Paule, Fair Maid of Guernsey, the Empresses, and Blush Queen, &c. Some sorts, such as Comte de Germiny, Elaine, &c., are keeping well. I can only account for this result by thinking the cool wet summer prevented the foliage and wood ripening sufficiently, and the plants are now overcharged with sap. I shall be glad to learn the opinions of more experienced growers at your side of the water.—THOMAS PHELAN, Clonmel.

CHRYSANTHEMUMS AT SOUTHWARK PARK, S.E.

WE are desired to announce that to-day (Thursday) an exhibition of Chrysanthemums at the above park will be opened for the first time in the new house recently erected by the Board of Works. The public will be admitted free of charge from 10.30 till dusk daily. This is another addition to the free public exhibitions of Chrysanthemums in the metropolis, and the second provided by the Metropolitan Board of Works.

AT FOREST HILL.

MESSRS. J. LAING & SONS have their annual display of Chrysanthemums in one of the long span-roofed houses at the Stanstead Park Nurseries, which a few weeks ago were filled with brilliant Tuberous Begonias. Now, though with less brightness of colour to attract, there is equally as much to interest in the large collection of varieties, both

old and new. Last year Messrs. Laing's plants were distinguished by their dwarfness, and good quality blooms were obtained from specimens that for grouping purposes were invaluable. This season, although there are sufficient dwarf plants for the margins of groups, the general stock has been allowed a little more extension, and a few experiments have been tried in another direction. Much smaller pots have been used for many of the plants than are usually recommended, and by restricting the blooms proportionately very satisfactory results have been obtained. Thus specimens in 48-size pots, both of incurved and Japanese, are in several cases bearing from two to three blooms of exhibition size and quality, and few would expect to secure such returns from plants in pots so small as that. Possibly the experiments may be extended in this direction another season. The plants are all in capital health, and notwithstanding the fact that in common with many others they were partially caught by the early frosts in October, they look very promising, the buds fine, mostly expanding freely, and apparently likely to come in well for the show time.

The collection comprises some hundreds of varieties, but we need only mention a few of the recent introductions or the present year's novelties. Foremost amongst these is Stanstead Surprise, the Japanese variety certificated at the last meeting of the National Chrysanthemum Society. It is a seedling of last year raised from imported seed, and is distinguished by its bold handsome blooms, with long, drooping, and curled florets, rich rosy crimson at first, slowly fading to pink, with a silvery reverse. Most of the blooms have been taken from crown buds; several others are advancing on the terminal buds that indicate similar characters, and which will come at the right time. One merit the blooms evidently possess—namely, good keeping properties, for some have been expanded two or three weeks, and do not seem much the worse now. Another seedling Mr. W. H. Burbridge raised a year or two before is coming in better condition this season than we have yet seen it. The blooms are of the Japanese reflexed type, with white fluted recurving florets, pure, full, and deep. A new Japanese from Délaux, named Madame Louise Leroy, is likely to be a good addition to the white varieties, the florets very pure, broad, and slightly fluted. It is considered as one of the best of the continental novelties sent out this year. There is quite a family of "Japanese Laings," the sterling qualities of which will be well displayed later on judging by the substantial appearance of the buds. M. John Laing and Madame J. Laing stand most appropriately at the head of the family both for size and merit; then come M. J. A. Laing and M. H. J. Laing, which should be followed by something extremely good in honour of Madame J. A. Laing, and then we may soon expect a Madame H. J. Laing. As regards the first four members of the family we were informed by the foreman, in strict confidence, that he had given them special attention for the credit of the firm.

Amongst other varieties worthy of note the golden yellow Japanese Gorgeous is very conspicuous, and should be useful for exhibition. Anatoli Cordiaier has medium sized blooms with narrow drooping purplish florets, a rather distinct shade of colour. Album fimbriatum, Criterion, Val d'Andorre, W. Stevens, Mdle. Lacroix, T. S. Ware, Mrs. Wm. Mencke, and Sarah Owen are also noteworthy in the Japanese group, while the incurved comprise good representatives of all the well proved varieties.

RICHMOND.

IT is somewhat strange that a town like Richmond cannot support a Chrysanthemum show, yet it would seem to be the case, for this year a dog and cat show has been substituted for the autumn display of Chrysanthemums and fruit. The district has so long been noted for its summer exhibition and the strong local enthusiasm, that it is to be hoped the substitution mentioned does not indicate a decadence in horticultural interest. The contrast, to say the least, is an unpleasant one, and it might be worth the while of those who still have a preference for the Chrysanthemums to endeavour to revive the autumn show. The best plan, where two shows are managed by one Society, is to keep the funds quite distinct, having a separate account for each. This has been found satisfactory in several such cases, as those who wish to support only one of the shows can readily do so, and it will soon be ascertained which is the more popular. The private collections of Chrysanthemums in Richmond itself are not very numerous, but the district around comprises many excellent growers who might be easily induced to compete. In the nurseries the plants are chiefly grown for cutting, and for this purpose Mr. W. Brown, St. Mary's Grove Nursery, has a large stock of plants. Elaine and other white-flowered varieties, with a few bright coloured sorts, are the leading favourites. Mr. Kinghorn also has several large groups grown with the same object in view, and abundance of blooms are obtained. But in both these nurseries the Chrysanthemums do not form the principal stock. Mr. Brown has an extensive, healthy, miscellaneous collection of Ferns, Palms, stove and greenhouse flowering plants, and bedding plants; and Mr. Kinghorn has a surprising stock of vigorous young Palms, the most popular sorts, like *Latania borbonica*, *Kentia Fosteriana*, and *Cocos Weddelliana* being largely represented.

TWICKENHAM.

CAMBRIDGE HOUSE, the residence of E. J. D. Paul, Esq., is close to Richmond Bridge, on the Middlesex side of the Thames, and there amidst some good general gardening, under the superintendence of Mr. J. P. Munro, Chrysanthemums have for several years been well grown, and the present season is no exception to the rule. Visitors at the Crystal Palace Show last November will remember the six grand blooms of Belle Paule which came from this garden, and several other

fine stands of blooms gained various honours at local shows. The collection of plants is not so large as some exhibitors would consider necessary, but every one is well grown, and the blooms expanding are in many cases of exceptional quality, only needing fine weather to keep them in good condition for the shows. For instance, the best examples of Edwin Molyneux we have yet seen are developing on crown buds, grand, deep, richly coloured blooms, showing the distinct characters of this variety admirably. *Boule d'Or* is another variety in remarkably fine condition, and there, too, is *Grandiflorum* opening well on crown buds in direct opposition to the experience of some growers. Deep, clean, incurved blooms and bright substantial Japanese characterise the collection; but the other sections are also represented, and up to the present Mr. Munro has ample cause to be satisfied with his prospects.

At Poulett Lodge, Twickenham, Mr. W. Bates grows some *Chrysanthemums*, and grows them well, as indeed he does everything else in his charge. He does not pose, however, as a champion exhibitor with these plants, which are grown more for grouping or cutting. Still good blooms have been obtained that would not disgrace many exhibitions to be held this year. It is surprising that often without any special effort better results are secured than attend the more elaborate systems of culture. Not that any kind of carelessness is advisable, but sometimes growers become too anxious; they try to hurry their plants too much, or to treat them too liberally, and in such a season as the present the effects are disastrous.

TEDDINGTON.

MR. WALTER FURZE, The Roselands, Teddington, is an enthusiastic amateur admirer of the *Chrysanthemum*, and with his gardener, Mr. Coombs, has on several occasions in past years proved what a combination of skill and enthusiasm can produce in the way of exhibition blooms. Judging by the condition of the collection this season we should think they will surpass their previous record as successful competitors. The garden is situated close to the Thames, within a short distance of Teddington Lock, and consequently fogs, mists, and atmospheric moisture generally are so abundant at this time of year that it could scarcely be considered a favourable situation for *Chrysanthemums*. Notwithstanding this, however, the blooms borne by the 450 plants grown are the freshest and best we have yet seen around London. Incurved, Japanese, *Anemones*, reflexed, all are well represented both in varieties and number of plants, but there are blooms of the first two groups that for depth, solidity and cleanness are not likely to be surpassed by many in 1888. *Empress Eugénie*, *Queen of England*, *Empress of India*, and others of the *Queen* type are grand, while some blooms of *Refulgence* must be ranked amongst the finest that we have ever had the pleasure of seeing. In the Japanese also the same remarkable substance is notable, and a good example is afforded by the beautiful white variety *Florence Perey*. This was recently shown before the Floral Committee of the National *Chrysanthemum* Society, but judging by the blooms exhibited it was considered too thin to be worthy of a certificate. Had the Roselands blooms been shown there would have been no hesitation about it, for one of these is nearly 4 inches deep, a grand solid bloom of white lace-like florets, very pure and handsome. Mrs. J. Wright is also as beautiful as when shown last year, Edwin Molyneux and several other new varieties being scarcely less conspicuous. But to enumerate all of first-rate merit would include a large proportion of the collection, and we can promise that competitors in the same classes as Mr. Furze who succeed in winning the first prizes will amply deserve them.

Very near to The Roselands is Weir Bank, the residence of T. P. Chappell, Esq., and there also *Chrysanthemums* receive attention with good results. A three-quarter-span Peach house, 100 feet long, is devoted to the plants, which, though somewhat later than their neighbours, are creditable productions, good blooms being notable of most of the leading varieties. Mr. Davis evidently understands the requirements of his plants and treats them well.—L. CASTLE.

COLD FRAMES.

How few people who have a piece of ground at their command have known the delights of a cold frame. Many people have a yearning for a bit of greenhouse, and look forward to the time when they may have one, even if rude and unconventional, but a well-built cold frame, properly cared for, can discount the greenhouse in some respects both as to results and expense, for a greenhouse is expensive, that is, if you expect to keep it in proper trim during long cold winters; and unless you have plenty of leisure time there are many days when you would want to delegate your duties to someone else, and take a breathing spell. A cold frame, however, can be run with the minimum of work and the maximum of results, provided you are not too grasping, and want to grow *Orchids* and exotics in it. But half-hardy plants can be grown in a cold frame to perfection, and I hope to show how this can be done, for the benefit of those who have never attempted to manage one.

First get your cold frame. This can be done on the assumption that you want one about 18 feet long and 6 feet wide. This will require six sashes 6 by 3 feet. For location, light being the essential in winter, an exposure to the south and east is the best, the morning sun in late autumn, winter, and spring being most valuable to all plants grown in frames. A stout inch plank for the back of the frame about a foot in width, and a somewhat narrower one for the front, to provide for the necessary slope towards the south or south-east, must be placed in the position selected for the frame, and the ends of the same kind of plank

may be united to connect the two. These end planks should be cut so as to slope from the rear to the front and inside of the frame, at distances of 3 feet apart; small pieces of timber 2 to 3 inches square may be nailed to connect the rear and front planks of the frame. These serve as rests for the sashes when they are placed upon the frame, and as braces to strengthen the structure, without obstructing the light to any great degree.

The rear of the frame is thus about 4 to 5 inches higher than the front when in position, and affords a slope for the sashes, catching all the meagre sunlight of winter, and shedding the rain and melting snow which may fall upon them. Some frames may be dovetailed instead of nailed if the builder wishes to have more solidity, but this is not requisite. In the autumn another tight plank about a foot wide should be placed entirely around the frame about a foot from the inner structure, and fixed in an upright position firmly by means of short stakes driven into the ground. The space thus formed should then be packed firmly with dry leaves until entirely full.

This forms adequate protection against frost, and is absolutely essential if one desires to keep the contents of the frame in a growing condition during the winter. Six cold frame sashes can then be procured from any dealer, and in purchasing sashes it is well to see that they are strongly constructed and well glazed and painted. Cheap sashes are of little use, and the glass ought also to be of the best make to prevent unnecessary breakage and insure clear passage of the sun's rays.

Straw mats, which are used by market gardeners, are essential, and these can be made on the place. For a frame 18 feet long three mats would suffice. To protect these mats from snow and rain, six wooden shutters 3 feet wide and 6 feet long can be made out of boards and painted to prevent them from rotting; these, with the mats, ought to afford ample protection to any frame built as described from the severest frosts of winter, and if to the beginner the paraphernalia seems formidable, there is comfort in realising that it is not expensive, and ought to last several years.

With the frame constructed, and the protection of its contents provided for, the soil within it ought to be a good strong loam, well trenched or spaded, and for certain kinds of plants, like *Pansies*, it will be necessary to add well-rotted manure in liberal quantities. In subsequent comments upon the various kinds of plants which can be successfully grown and flowered in a cold frame, it will be shown which do better with or without manure.

The general idea prevails that manure is essential to all kinds of plants, but experience has shown that in instances where good loam can be provided, it is not only not essential, but an injury, notably in the case of *Violets*. This statement may be questioned by some, but close observers of the disease of spot, which has made *Violet* culture in many localities an impossibility, have found that the use of manure is one of the causes of the disease.

In a cold frame different kinds of soil may be provided for certain plants, according to their needs, but most of them are not exacting in this respect, all other essentials being provided for. In a cold frame many kinds of plants can be grown, to the delight and satisfaction of the owner. If a greenhouse cannot be had the frame affords an excellent substitute. There may be grown *Violets*, *Pansies*, hardy *Primroses* or *Polyanthus*, *Japan Primroses* or *Primula cortusoides*, one of the most beautiful plants we have, *Anemone coronaria*, a most gorgeous flower, in all shades of blue, scarlet, white, pink, &c. *Christmas Roses* or *Hellebores*, *Daisies*, tender bulbous plants, like certain kinds of *Iris*, *Triteleias*, *Ixias*, *Freesias*, &c., and many other things which, as one goes on gaining knowledge, offer themselves as delightful substitutes for the regulation greenhouse stuff which one sees on every hand. After experience with both greenhouse and cold frame, one hesitates as to which he would sooner part with, with an ultimate mental reservation in favour of the latter.

A cold frame needs attention. It must not be expected after it is constructed and planted that there is nothing more to be done. On the contrary, as soon as winter sets in it must be uncovered on all bright days, when the sun shines sufficiently to counteract the outside cold, and the sashes must be tilted a little to give air, unless the temperature is below freezing point, and in the afternoon, just before the sun leaves it if the weather is cold, the mats and shutters can be put over it, and it can be closed for the night. As the sun's heat grows and the days lengthen more exposure can be given until all danger of frost is past, when the sashes can be removed altogether. The contents of a frame, however hardy, are never improved by being frozen, so one must vigorously guard against Jack Frost.

If all this bother seems like drudgery then it had better not be attempted, but it is assumed the owner of a cold frame, who has mastered its management and achieved the best results, will feel that no effort or attention is too great for the proper care of it. Its delights and surprises are manifold, and many a toiler among commonplace surroundings and influences would find it a relief from the irksome cares which fall to the lot of most of us.—(*American Cultivator*.)

PLUMIERA BICOLOR.

At the last Floral Committee meeting of the National *Chrysanthemum* Society, Mr. H. Cannell brought up a fine example of a plant he had without a name, and after seriously puzzling the majority of those present, it was determined to be *Plumiera bicolor* (fig. 47). Though the

Plumieras are old inhabitants of our houses, they are now seldom seen, yet they are amongst the most beautiful members of the family Apocynaceæ. The flowers are large and fleshy, rather suggestive of the

admirably with the substantial flowers. *P. alba* is another species with white flowers. *P. tricolor* has its flowers deeply tinged with rosy crimson, and there are several others of various tints. All are shrubby

FIG. 47.—PLUMIERA BICOLOR.

Oleander, and in the case of the species now illustrated they are pure white with a rich orange centre, also possessing a powerful but agreeable perfume. The leaves are large, of a glossy green hue, contrasting

plants, sometimes attaining the dimensions of small trees, requiring a rich loamy compost, abundant water, and the temperature of a stove or warm conservatory.

EVENTS OF THE WEEK.—The principal Chrysanthemum Shows for the present week are the following :—Southampton to-day (Thursday); Kingston, November 6th and 7th; the National Society at Westminster, November 7th and 8th; Portsmouth, November 7th, 8th, and 9th; Teddington, November 8th, and the Crystal Palace, November 9th and 10th. Messrs. Smail & Co., 123, Fenchurch Street, E.C., announce sales of bulbs, Azaleas, &c., on November 5th, 7th, and 8th; and Messrs. Protheroe and Morris will hold a sale of nursery stock on November 6th at Mr. T. S. Ware's nursery, Tottenham. The British Fruit Growers' Association will hold a meeting in St. Stephen's Hall, Westminster, on November 8th.

— **GARDENERS' ORPHAN FUND.**—At a largely attended Committee meeting held on Friday evening last, Mr. G. Deal presiding, donations were announced of £11 8s. 8d. from the local Secretaries :—£10 from Mr. A. Dean, including proceeds of a concert at Chiswick; £7 12s. from Mr. W. Wildsmith, the results of a garden fête; £5 from the Hon. and Rev. J. T. Boscawen; and £1 from the Oxford Carnation Show, per Mr. E. S. Dodwell. Receipts were presented from the guardians of ten children for moneys received by them, and accompanying letters showed how greatly the assistance was appreciated. It was stated that Mr. O. Thomas of Chatsworth is making preparations for a floral fête in the Stevenson Memorial Hall, Chesterfield, on November 14th, for the benefit of the funds. Mr. Bishop, The Grove, Teddington, was appointed local Secretary for that district. Sub-committees were appointed to consider special matters, and general routine business was transacted.

— **MR. C. ORCHARD** writes : "Last SATURDAY IN THE ISLE OF WIGHT was like a summer's day. The hedgerows full of clusters of ripe Blackberries, and the cottage gardens were still gay with their summer occupants, mingled with autumn Roses and *Sœur Melanie* Chrysanthemum, which is now blooming profusely out of doors here. It is only in the lower gardens that the late frosts cut the Dahlias and other tender flowers down. The Myrtle trees are now beautiful with their white flowers and buds. Chrysanthemums in this neighbourhood are much better than I expected to find them, many of the Queen family being very forward." We may add that our correspondent, in addition to his present duties, has been entrusted with the management of the Bembridge Hotel, an excellent house and favourite seaside resort of visitors in the summer.

— **CHISWICK GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—At the annual general meeting of the members of this Institution held on Friday evening last, October 26th, Mr. George Gordon was unanimously elected Chairman of the meetings during the ensuing session. The following papers were promised to be read on the under-mentioned dates :—November 2nd, Opening Address by the Chairman, Mr. George Gordon; November 9th, "What Constitutes a Gardener," Mr. John Fraser; November 23rd, "Roses and their Cultivation," Mr. T. Bones; November 30th, "Economic Plants of the Order Labiatae," Mr. A. Parsons; December 7th, "An Over-supply of Gardeners—a Remedy," Mr. J. Barry.

— **SWEET-SCENTED FLOWERS.**—"W. B." at page 342 evidently thinks that other people's corn must be measured with his own bushel when he states that scentless Roses ought to be discarded. This is a common error that many people fall into, not but what I am very fond of sweet-scented flowers myself, but a gentleman I had the honour of serving would not have a strong-scented Rose or Carnation in the house, much as they were liked in the garden. Another gentleman, the owner of a very large garden, was of the same opinion. Nor are these cases exceptional. Either for a drawing-room or for the decoration of the dining table sweet-scented flowers I find are not at all appreciated. Self Carnations, like Roses of a pleasing colour, have a rich appearance by artificial light, and when so used the less scent the better.—**A DECORATOR.**

— **GARDENING CHANGES.**—We understand that Mr. John Crook has left Farnborough Grange, Hants, through the death of the late Wm. Sherwin, Esq., who was a great lover of horticulture. Mr. Crook had charge of the gardens, &c., for eleven years.

— A SLIGHT error occurs in my note on **NARROW VINE BORDERS**, page 382, twelfth line from the top of the column, which I should be glad for you to set right in your next issue. Instead of "lime and broken bricks," it should read, "mixture of loam and broken bricks."—**W. S.**

— "H. D." sends the following notes :—"During a recent visit to the well-managed gardens of the Earl of Cork, **MARSTON HOUSE, FROME**, I noticed some exceedingly fine *Bouvardias*, the plants being in 5 and 6-inch pots, and were bushy little specimens completely studded with buds, and will doubtless prove invaluable during the next few months for supplying abundance of their bright scarlet and snowy white blossoms, which are so effective when arranged with *Maidenhair* Fern fronds in the form of sprays and buttonholes. The double forms find most favour with Mr. Iggulden, who has evidently hit upon the right method for growing *Bouvardias* well.

— "IN the same garden my attention was drawn to a most useful Fern which is not so much grown as it should be. I refer to **ADIANTUM MUNDULUM**. All who have a great demand for Fern fronds in a cut state would do well to secure a stock of this variety, the fronds of which are especially suitable for making sprays and buttonholes, being of the right size for that purpose, and stiff enough to be used without wiring.

— "ON a shelf at the back of a stove was a fine healthy clean stock of **CALANTHE VEITCHI**, which had made extra strong growth, and promises in due time to yield a plentiful supply of their choice and beautiful blossoms. The plants were growing in a mixture of peat, sphagnum, and charcoal, as Mr. Iggulden finds they do not thrive in the loam he is able to procure, and although others may grow *Calanthes* equally well in loam, the condition of the plants at Marston plainly indicates that the treatment they receive suits them in every respect.

— "SOME very fine fruits of **HERO OF LOCKINGE** and **BLENHEIM ORANGE MELONS** were ripening at the time of my visit, also a large example of a variety raised by Mr. Miller of Rood Ashton Park; and although growing to a large size there is nothing coarse about it, the outline of the fruit being even and beautifully netted, and the variety will doubtless prove very useful for growing a few large fruits for special occasions.

— "TOMATOES IN PITS are trained in a simple and novel way at Marston. Common hurdles are fastened about 18 inches from the glass, over the surface of which the shoots are trained at will. Treated in this way the labour of tying and training is reduced to a minimum, the fruits can be fully exposed to the light, and no further trouble is given in supporting the heaviest fruits."

— **POTATOES AND PEAS IN 1888.**—My Potatoes were planted in the garden in the second week of April. The varieties were Webb's White Beauty, Perkins' Snowdrop, Improved Ashleaf, and Schoolmaster. The first-named turned out a splendid crop of good large tubers nearly all good. Perkins' Snowdrop were fine, but many of them were diseased. Improved Ashleaf were quite a failure both as to crop and diseased tubers. Schoolmaster, again, were not good with me, the bulk of them were bad. My soil is heavy and well manured. I planted Sutton's Fiftyfold, Beauty of Hebron, and Reading Russet in the field, and had a grand crop of each of them, but Reading Russets were three parts diseased, Beauty of Hebron was one part diseased, and Sutton's Fiftyfold were the same. The soil is light on the top of a bank, and I should have thought was well suited to them because it allowed the water to run off the rows.

— **WITH** regard to **PEAS** I grew twelve sorts—William I., Early Bird, Duke of Albany, Telephone, President Garfield, Fortyfold, American Wonder, William Hurst, Perfection, Yorkshire Hero, Wordsley Wonder, and Walker's Perpetual Bearer. The dwarf Peas with me ran up to 2 feet high, and were so thickly covered with pods, and we had such a wet season, that they never ripened, and I had to pull them up without getting a crop. All the earlier sorts were as bad; they ran up to 6 or 7 feet, and the peas I had from them were not good. This Walker's Perpetual Bearer Peas, however, made up for. I have been picking pods with nine and ten peas in for the last month, and they have been bearing and blooming after being exposed to 10° of frost.—**JOSEPH PALMER.**

— **GISHURSTINE.**—We are always reminded of the approach of "bad weather" by samples of this well proved and excellent dubbing for boots. Like the Gishurst Compound of the same inventor, it wears well and makes boots wear the longer for its application. Workers on

land and amongst manure, also young gardeners in houses whose boots are half their time wet, as well as all persons who have to pass through the slush of winter, may be reminded of the comfort and advantage they may derive by the systematic use of this cold-preventer and boot-preserver they have often seen advertised, and those of them who have not tried it are advised to do so, for it is good.

CONFERENCE PAPERS.

CANKER: ITS CAUSE AND CURE.

By MR. JAMES DOUGLAS, ILFORD, ESSEX.

THIS troublesome disease in fruit trees has very frequently been the subject of discussion in the gardening periodicals and elsewhere. Nearly every gardener has had to deal with it in his experience of the details of fruit culture, and as I had considerable experience of it some twenty-five years ago, in an old Essex garden, I may at least claim to bring it forward as a subject for discussion.

At the outset it may be taken for granted that it is absolutely necessary to ascertain the cause of a disease before any attempt can be made to find a remedy. The late Mr. Robert Thompson, author of the "Gardener's Assistant," and Superintendent of the Royal Horticultural Society's Garden at Chiswick, writes on canker with considerable diffidence. In the work above cited, page 381, he says: "The cause of canker is imperfectly understood, and so consequently is an effectual remedy."

His idea of the causes of canker, as summarised in his admirable work, are:—

- I.—Sudden checks to the vegetation of the tree, especially in spring and the early part of summer.
- II.—Derangements of the flow of sap from vicissitudes of heat and cold, as well as of moisture and dryness.
- III.—Unskilful and severe pruning.
- IV.—Vitiation of the sap by deleterious substances in the soil or subsoil.
- V.—Dryness at the root doubtless gives rise to a species of canker, which manifests itself on the younger branches and on the shoots.

Referring also to Lindley's "Theory of Horticulture," page 110, it is stated that a Mr. Reid of Balcarras had shown "that one of the causes of canker and immature fruit, even in orchards, is the coldness of the soil. He found that in a cankered orchard the roots of the trees had entered the earth to the depth of 3 feet; and he also ascertained that during the summer months the average heat of the soil at 6 inches below the surface was 61°; at 9 inches, 57°; at 18 inches, 50°; and at 3 feet, 44°. He took measures to confine the roots to the soil near the surface, and the consequence was the disappearance of canker and perfect ripening of the fruit."

Another cause has been suggested—viz., insect agency. But this view of the matter will probably not be sustained by practical gardeners generally. That insects of various kinds, including that troublesome pest American blight (*Aphis lanigera*), will penetrate into the cankered part for shelter is likely enough. Indeed I can assert they do; but they are not there as the cause of canker, but because the cankered part affords a secure resting-place, which the smoother, healthier portion of the bark does not. Indeed I can also assert that cankered trees may be found in the garden with insects upon the affected part, and others near them also cankered with no insects upon them.

My contention is that canker is caused in two ways, and affects two different parts of the trees. Perhaps the most serious disease is that which affects the trunk or larger branches of the trees. This I hold is caused by the roots pushing downwards into cold, undrained, or unsuitable soil. The other aspect of the disease is that which lays hold of the twiggy portion of the trees, for even the one-year-old shoots do not escape. The immediate cause of this is probably owing to the rupture of the sap vessels by frosts, when the sap is in an active state. But I have a firm belief that the primary cause is also to be found in the state of the roots, which being in an inactive state owing to unsuitable soil, or their penetration to a great depth, prevents the perfect ripening of the wood, or maturation of the blossom buds in the autumn.

I come now to my own experience in our old garden twenty-five years ago. There were upwards of 100 trees of various sizes, some only a few years old, others 100 years planted at least. Most of them were cankered, and in places where the old trees had been removed and young ones planted canker showed itself in a few years.

The soil was light, over a gravel subsoil, and was naturally drained; the water did not stand on the surface for any length of time, even in very wet weather. I was confident that want of drainage had nothing to do with it, and that the fault was in the cultivation. Young trees seldom do any good planted amongst old ones, even if the soil has been

well dug up and enriched with manure where the roots are to be placed. They require a wider and better field for their ramifications. I found I had to make gravel paths as well as fruit borders, and as most of the old trees were on the wane, and the young ones of but little value owing to their cankered state, it was thought best to remove them. But they were not all removed at once, as it was necessary to keep up a supply of fruit for household use. A space about 30 feet wide was lined off through the whole length of the garden, and was cleared of all trees and bushes. In the middle was a space 6 feet wide for a gravel path. The borders on each side, about 12 feet wide, were trenched where possible 2 feet deep, and we found the gravel cropped up in places within a foot of the surface. Where this was the case the gravel was taken out and used to make the path, the soil from the path being used to fill up the space from whence the gravel was removed. A good dressing of decayed farmyard manure was worked in with the operation of trenching, and as we could obtain good clayey loam a barrowload of it was spread out over 2 square yards, and 6 inches below the surface; a thin layer of decayed manure was placed on the ground before the loam. This was easily done as the work proceeded; one man could wheel in the loam and manure to two at work trenching.

When the work was finished we had a good gravel path with Box edging on each side, and the borders, through the trenching and manuring, were about 8 inches higher than the surrounding ground level. I had to plant the trees soon after the trenching was finished; they were Apples, Pears, and Plums on various stocks and in considerable variety. We planted them but 6 feet apart at first, and when they were planted a portion of good decayed turfy loam was placed round the roots. With this treatment, as might be expected, the trees made good clean growth even the first year.

As we manured rather too heavily by placing in two layers of fat stuff I thought it best to retrench the ground the next year, lifting the trees as the work proceeded. I found they had made a mass of fibrous roots into the loam, and when the trees were replanted again quite another barrowload of loam was placed round the roots, but no manure this time. However, round the roots of each tree some decayed frame manure was placed to keep the frost from them.

The trees made good clean growth again, and formed plenty of blossom buds. But I found 6 feet was too close even for Apple trees on the Paradise stock, and they had ultimately to be removed from 9 to 12 feet apart. In the course of the next ten years other borders were made, and in some cases the trees which were too close to each other were thinned out to furnish them. Many of the old cankered trees remained in proximity to the young ones for quite ten years, and with some two or three unimportant exceptions none of the young trees cankered. This shows, I think, if the disease had been caused by insects they might have travelled from the old diseased trees to the young ones. It was some seven or eight years before any canker appeared, and then only on the Dumelow's Seedling or Wellington. These trees were lifted, the canker cut out, and they were replanted again with fresh loam under and over the roots. The cut out portions soon healed over, and I saw no more of the disease.

The object I had in view was to encourage the roots up to the surface, and to keep and feed them there. The entire border quite close to the surface was full of roots, because it was not dug over, but merely scratched with a fork or hoe; and during winter and summer there was a thin layer of manure over it. Within the borders was the kitchen garden squares, well manured, to be cropped with vegetables, and the roots ran into this freely. We were well within the London fogs being less than seven miles of the Bank of England. In our new garden not much further out we had to do the same sort of work, but the soil was much better, being a medium clay of considerable depth, and nothing more was necessary than to trench the ground twice over in order to incorporate the top and bottom soil well together. We had to drain it, and find a good outfall for the water. In such a case the drains should be about 6 yards apart.

I have brought this subject forward as much in the interest of amateurs who own small gardens, and who do most of the work themselves as a relaxation from sedentary occupations, as in that of gardeners. It is quite true that some classes of soils are more suitable to fruit culture than others, but my experience is that some soils are condemned when neither the soil nor the climate, but the culture alone is to blame. Only the other day I met a person who has several hundreds of fruit trees in his garden, most of them young ones, and, a considerable proportion are showing canker on the larger branches. I examined the soil, and found that it had not been broken up more than 10 inches deep; and, further, all sorts of vegetable crops were planted

close up to the trees. This system of culture can satisfy no one, and it cannot be profitable. I fancy many good gardeners will bear me out when I say that want of preparation of the soil, and subsequent neglect of the special requirement of each class of trees, is the sole cause of canker.

Having found a cause, I would suggest the remedy. In the first place, it may be remarked that heavy clay soils nearly always require to be drained, and a free outfall provided for the water. Three feet depth of drain is sufficient, with a main drain at the lowest part of the garden 3 feet 6 inches deep.

Secondly, trenching, or at least stirring, the soil to the depth of about 2 feet is necessary. But I would not invariably throw the subsoil up to the surface, but would always stir up the bottom to the depth of 8 or 9 inches with a fork, and if the soil could be trenched twelve months before planting all the better.

In the third place, good healthy trees should be selected; they ought to be carefully lifted, and planted as soon afterwards as possible. Care must be taken to keep the roots in a moist state from the time they are lifted until they are again in the ground. Spread the roots out carefully when planting them, and work the soil well in amongst them. Trees on the free stocks should be planted the same depth as they were before. Those on the Paradise and Quince stocks, or, in fact, any dwarfing stocks, should be planted to the union of the stock and scion. It is also of great advantage to the trees to have a mulching of decayed manure around the roots after planting; and if they are exposed to high winds, they ought to have some artificial support until they are well established.

Lastly, as to the pruning and training. I seldom do any pruning in winter. It is a more pleasant occupation in summer, and is a very simple operation, merely consisting in thinning out the young wood when it is too much crowded, and pinching off the points of any vigorous young growths that are likely to run out too far for the others. If they grow too much it is easy to dig round the circumference of the roots, and to cut underneath to sever any roots that are running directly downwards. This will be enough to throw any tree into bearing. To allow a fruit tree to form a thicket of wood in the summer, and then to cut it all off in the autumn, is the right treatment for a pollard Willow, but will not do for fruit trees of any kind. There should be more reverence for life in the mind of the pruner than for such reckless pruning to be possible.

It is quite time that a better system of fruit tree culture should be adopted in small as well as in large gardens. Why should amateurs purchase fruit when they can grow it themselves, and have all the pleasure as well as the profits? It is useless to sit down and blame the climate, the soil, or anything else, when the real cause is a bad selection of varieties, or bad cultivation. Let the old worn-out cankered trees be rooted out from old gardens, and their places be filled with approved sorts likely to do well in the neighbourhood, for each district has its special varieties.

Preparation of the ground by trenching and manuring is necessary, and whether the soil is light over gravel or a clay soil over heavy clay, the results will be satisfactory, and justify all the expenditure.

CULTIVATION IN JERSEY.

By MR. CHARLES B. SAUNDERS.

THE Island of Jersey, being so noted for the growth and cultivation of fine fruit, especially Apples and Pears, I venture to offer a few remarks upon the modes of culture and the varieties cultivated, thinking they might be acceptable to the Committee, and also to the general body of horticulturists interested in the production of these health-giving and palate-pleasing fruits.

Jersey being the most southerly of the group of islands in the Bay of St. Michael's, and the slope of the land being from north to south-west, enjoys a very favourable climate; the general moisture, owing to its position and the saline air, which almost always may be felt blowing over its surface, renders it particularly adapted to the growth of Pears. The soil is a good loam upon a substratum of clay retentive of moisture, which suits the Quince stock upon which most of the Pear trees are budded or grafted. There are localities along the coasts of which the soil is much mixed with sand, owing to the continuous drift in stormy weather, whilst some parts of the western side of the island are so much exposed to the Atlantic Ocean as to be entirely unfit for fruit culture and scarcely worth cultivating, the cereals and root crops growing upon them being very often subject to serious injury from the force of the westerly gales. Now it is easy to understand why the most protected and best sheltered situations are selected for the growth of the finest and best kinds of fruit. Apples are grown on the higher and drier parts

of the island, where the land is stiff enough and the drainage good, hence the orchards, where the more ordinary kinds are grown for the manufacture of cider and general consumption, are generally surrounded by hedgerows from 5 to 8 feet high, and planted with Elm and other descriptions of forest trees. The Apple trees in these orchards are generally grafted 6 feet from the ground, and have spreading circular heads, which are perfectly beautiful when in bloom. Very many of us can recollect when the Weigelas of sorts were first introduced that their great recommendation was that they were as "beautiful as Apple blossoms." Were not Apple blossoms beautiful before then?

These orchard trees which make such a beautiful display of flowers, and produce in favourable seasons such an abundance of fruit, are much neglected, and allowed to grow in a confused mass of branches. To scientific horticulturists it seems a pity that, where Nature does so much, man should do so little in the way of pruning, so as to give the trees a more regular form and better appearance. You will, I think, gentlemen, agree with me that judicious pruning—i.e., removing weak and superfluous branches, would have the good effects of improved appearance, more healthy growth, and finer fruit. The general character of the growth is so vigorous as to render it unnecessary to prune the extremities of the shoots, except for the sake of shaping the trees and balancing the heads, but "thinning out" is the style of pruning requisite.

The finer descriptions of Apple fruit are grown in gardens sometimes against the walls, on espaliers, or on the long cordon system. The dwarf cordon is not much practised, nor is it desirable, inasmuch as the growth, in spite of the Paradise stock upon which the trees are usually worked, becomes so strong that it requires constant cutting back to keep it within the desired limits, and this constant repression of growth is not conducive to fructification.

The finest Ribston Pippin Apples are grown upon south walls in sheltered gardens, trained upon the fan system. The strong radiative shoots being selected to form the frame of the trees, and the lateral and weaker branches being pinched and pruned off, so as to get fruit spurs to form. It is an excellent system, barring the disadvantage of the early maturity of the fruit. Very few other sorts are thought worthy of wall culture. The dwarf bush, the open standards, the rider or tall standard trees are all acceptable forms of garden trees, where the space is sufficient; and such varieties as Early Stibberd, Red Astrachan, Lord Suffield, Hawthornden, Red Quarrenden, Hooper's Seedling, Downton King, Golden and Walton Pippins, Grand Alexander, Cox's Pomona and Orange Pippin, Court of Wick Pippin, English and Dutch Codlins, &c., are grown freely on Paradise as well as other stock, and take but little space. It is not unusual to see crops of fruit considerably above the weight of the trees producing them. Planting Paradise stock Apple trees in rows 6 feet apart, and the trees at 3 feet apart in the rows, suggests a system of culture which might be made remunerative, and were it not for the constant changing of tenants from one piece of land to another, might be advantageously practised. It is not so here; most of the fine fruit is produced on accidental trees, either found in gardens on taking possession, or planted by incoming tenants. Taking into consideration the time necessary to get a stock of trees into a good bearing state, few tenants would care to adopt any system of planting or training from which they would not derive some immediate advantage.

The cultivation of the Pear has been so very remunerative for years past that it has been made a subject of more general study and system. Many of the old gardens, established half a century or more ago, offer evidence of the walks having palisades on both sides, for the purpose of training Pear trees upon them, and in some cases the palisading has been double, so as to admit of trees being trained on both sides, 1 foot or less being the intervening space between the rows of palisades. Trees planted in this way are generally productive, the main lateral branches being trained and supported horizontally, a regular and continuous supply of sap is provided during the growing season for the development of the fruit. This system has and does answer well, and as long as the trees continue healthy they bear good crops of fruit, the size of which much depends upon the amount of thinning practised. Against walls, both horizontal, fan, and cordon styles of training are practised, all of which answer well in the hands of careful attendants. Dwarf bush and pyramidal trees are also grown, many acres of ground being devoted to the cultivation of the celebrated Chaumontel Pear. The great number of excellent varieties grown, and their exquisite though varied flavours, make the Pear a fruit of general acceptance, though few varieties are much grown. Citron des Carmes, Jargonelle, Williams' Bon Chrétien, Louise Bonne, Maréchal de Cour, Bcurré d'Amanlis

and Beurré Diel, Duchesse d'Angoulême, Doyenné du Comice, Cbaumontel, Glon Morceau, and Easter Beurré are more often met with than other varieties; and amongst culinary Pears the Belle de Jersey (Syn. Belle Angvine), and Catillac, or Pound Pear, are considered the best.

A rich, strong loam suits the Quince stock best, a lighter soil suits the free stock for Pears. The advantage of growing Pears on the Quince as a stock is early fructification, whereas the generally accepted axiom respecting Pears grafted on the free or Pear stock is, that—

"He who plants Pears,
Plants for his heirs."

There are but few large Pear trees on the island, occasionally one or two are met with, towering above the Apple trees in the orchards, but such trees are the exception; and land is so expensive in Jersey that no room can be spared for unproductive trees (which is the case whilst the tree is growing).

The Jersey farmer, cultivating 20 acres of land, and making a comfortable living off so small a surface, cannot afford to allow a single perch of it to remain unproductive, and every square yard is made to contribute towards the general expenses. The space allotted to kitchen gardening and fruit culture is generally near the homestead, the pathways being planted on either side by bush Apple and Pear trees, Currant and Gooseberry trees filling up the intervening spaces in the rows until the trees have grown sufficiently large to cover the whole space. These highly cultivated and richly manured pieces of ground are made to produce crop after crop in rapid succession. No sooner is one crop off the ground than another replaces it (organic, and not artificial manures being used). The trees get the benefit of these repeated dressings and the manipulation of the soil.

FRUIT CULTURE ON SMALL FARMS OR ALLOTMENTS.

BY MR. S. RAWSON.

IT is a well-known and acknowledged fact that spade culture pays, and pays well. An Italian proverb says, "The plough has a share of iron, the spade has an edge of gold." That land so cultivated is better for the digging and double digging, and more remunerative than larger holdings, which are susceptible only of the ordinary farming operations, goes without saying, as results have proved all through this country, and fact demonstrates again that hand labour is now as necessary to the tillage of the soil, at any rate in this country, as ever it was before the introduction and application of steam power to land culture, and that the profits from the cultivation of small holdings pay better than anything else, and for this reason that there is more attention paid to a small area of land of which the tenant has to take the benefit than is usually given to the large farms.

If the landlords would help their cottagers, or holders of, say from 1 to 10 acres of land, assist them by lending them their implements and tools, supplying them with seeds, and if necessary with labour, surely with the extra productiveness of the soil there would be extra profit, and it would be to the advantage of the tenant to share it with his landlord, and on the other hand to the latter a benefit to receive a consideration for the use of his money and implements, at the same time knowing that under the circumstances the value of his land was being improved.

So much for the assistance and opportunity to the small holder. Now as the disposition of his produce when grown. In this again his landlord might help him as the landlord at the same time might help himself. The landlord generally in fruit-growing districts is a man of means, able to send his produce to market either by road or rail as may be preferable to him. Not always having a full load, why could he not carry his tenants' small quantities to market if by road, or if by rail include them in the consignment of his own and save the small grower the difference in the rate of carriage between large and small consignments? There seems no reason why it should not be done, at any rate whilst railway rates are as they are. Upon an improvement in that direction the small cultivator may be able with good luck to get his goods to market at something like a reasonable tariff.

There is another way, as I have often pointed out, to enable the small growers to market their goods—i.e., by a combination among themselves to make up, say a truck load for instance, to be consigned at their joint expense to market, instead of taking them by road. I am not now speaking of growers who attend market, and who have the means of transporting goods by road, but the "small fry" who cannot afford to go to market, and there are thousands who cannot, but who would be only too glad to turn their bit of land to better account but for the trouble and expense of sending to market, and of the indifference of their larger growing neighbours to accommodate them either by carrying their parcels to market or even buying from them, the former

having too much on their own hands unsold to enable them to buy, and the disposal of their own goods occupying their whole time whilst the market is on.

In country districts, therefore, the Companies or Associations of which I have previously suggested the formation, could by their agents collect and provide the means of conveying in bulk the produce of small growers, and sending direct to the Company for sale in this manner save the cost of extra carriage. There is no need to remark upon packing in this instance, for the smaller the grower, my experience teaches me, the greater the care bestowed upon the picking and packing.

Coming to the question of collecting in country districts where the railway stations are far apart, I think the system of roadside tramways would be very useful. I remember some years ago finding one between Shipston-on-Stour and Stratford-on-Avon (Warwickshire) of great utility, and which obviated the necessity of sending by cart to a railway station about four miles distant (Moreton-in-the-Marsh). This made a vast difference to the small growers from whom a great portion of the produce was purchased, as having the means of sending the goods at a very low rate per ton, better prices could be paid for the goods if bought, or if sold on commission better returns might be made. In country districts the means of transport might be made much easier and cheaper by the adoption of a similar system at a trifling cost (in a primitive way) as that I have mentioned. For instance, nearly treble the weight of goods may be carried on tram lines by the same horse power than can possibly be done on the road by ordinary cart or waggon conveyance.

Another mode of transit is the parcels post, which certainly is a most convenient and speedy system, and especially useful to the ordinary consigner of small quantities, but the limit, 11 lbs., is too low to allow of its being generally beneficial to small growers. Taking the limit, 11 lbs. postage, 1s. 3d., and comparing it with the present rates by passenger trains, although a parcel of that weight may be sent to any place for 1s. 3d., still supposing that it has only to be sent thirty miles the railway company will take it and deliver it for 6d.; for fifty miles, 8d.; for one hundred, 1s.; for two hundred, 1s. 6d.; and for any distance above that 1s. 8d. So considering that most of the small parcels do not, as a rule, travel over the longer distances the advantages of carriage by the railway companies are eminently paramount. In considering this part of the subject I have not had regard to the "dealer's rates," which by passenger train would be about half the above-mentioned railway rates. I do not, however, see why the parcels post could not be more extensively adapted to the general requirements of the small growers. There is an existing staff, horses, vehicles, and everything to cope with the carriage of parcels of increased weight, and if the railway companies can carry 28 lbs. for 2s. 4d., why should not the parcels post, who have far greater advantages than ordinary consigners, give the public the advantage of part of the profit, and carry parcels of greater weight at reduced rates, even below those of the railway company, whose machinery they are bound to use? I may mention here once more the grievous subject of railway rates that I have recently had experience between home and continental rates of carriage. A short time ago I bought large quantities of fruit and vegetables at Lichfield, near Birmingham. I consigned 10 tons in one day, and I find that comparing the rates with those charged from Rotterdam or Antwerp for the same class of goods the carriage of one ton from either of the latter places at the same rate as charged from Lichfield to Birmingham, taking mileage into account, would amount to about £15 for fruit, and for a ton of vegetables, £8 15s. The charge from Lichfield to Birmingham per ton for fruit is 12s. 6d.; from Rotterdam, £1 12s. 6d. For vegetables, 7s. from Lichfield; from Rotterdam, 22s. Distance from Lichfield to Birmingham sixteen miles, and from Rotterdam to Birmingham about four hundred miles. This I can at once evidence by carriage notes. In noticing my small book, "The Producer and Consumer," Mr. Gladstone to whom I am much indebted for his remarks upon it at Hawarden, on the 23rd of August last, said, "That if truck hire were charged without classification at a mileage rate it would no doubt be a good thing for the growers, but that he was not aware that such a system had ever prevailed." I may say that it was certainly a custom years ago, inaugurated by my late father, in the Worcestershire district, and if again resorted to would be doing good to growers without in any way injuring the railway companies.

NOTES ON BIRDS.

IT is a long time since I sent a note to the Journal, as it is easier to read the notes of others than to take part in the work but if all acted on the same principle the interest in the Journal would be much curtailed.

I have read the notes on birds on pages 390 and 391 with much interest, and as my experience, from careful observations, differs in some respects, perhaps I may be permitted to make a few remarks on the subject. Although I have not much sympathy towards sparrows in general, it is only fair to them that they should have their due as regards the good they do. I have read very many articles on sparrows and their doings, especially in *Poultry*, some months ago. I allow a few pairs to build around my premises (four pairs have been with me last summer, and some have been allowed to take off a brood of young) for purposes of observation, which gave me an insight into the food they took to their nests. I have no hesitation in stating that they destroy an immense quantity of caterpillars, grubs, insects, moths, and cockchafers, which they strip of legs and wings to feed their young, which is varied with corn and meal, particularly from the pig trough if obtainable. I was once much interested in seeing an old hen sparrow feeding—or attempting to feed—young wrens with pig food. The sparrow had been previously robbed of her own young ones.

During the past summer, when the caterpillar plague was in full swing—at the time it was difficult to find a perfect leaf on the Apples or Oaks—I watched the sparrows very carefully, and it was interesting to see them going to and from the Oaks. The barer the Oaks the more attracting to the sparrows. I walked quietly under the trees and watched how industriously they were tearing open the curled up fragments of leaves and taking out the grubs or chrysalis, with which they either fed the chirping fledged young with them or took them off to their young in the nests, as the case might be. As the sparrows cleared one lot of trees they went further afield, and I found them in large flights at least a mile from their homes, away out in the fields in the dried up and withered-looking trees with not a leaf left on them except the fragment which enveloped the chrysalids of the beautiful little green moths.

As regards nesting, I will not allow the sparrows to take the nests from the martins. If they persist in it they are driven into Elm trees where shooting will not matter, and down they come. I have known a cock sparrow bring home hen after hen, three in a day, until he had to fall. But I give them boxes in convenient places to build in—only a few—and then they are under control, and I generally give the eggs to children and not allow them to hatch. They continue to lay all through the summer. On one occasion I placed a brood of young sparrows in a cage, and found at least a score of cockchafers dropped into the bottom of the cage for the young by the old birds, and as the young were not old enough to peek, the insects were lost as food. These I have in my possession now. It would take too much space to particularise other useful birds as caterpillar destroyers.

As regards sparrows, swallows, and martins taking bees, as mentioned by Mr. W. E. Burkitt, I am very pleased to say such is not my experience, although I have watched them many an hour. On the other hand, I can assure readers that I have scores of times seen both martins and swallows followed by bees on the wing, for what purpose I was never able to satisfy myself, without it is curiosity, as seems to be the case when bees and wasps fly round persons without attempting to sting. My stock of house martins round the premises this season has been fifteen pairs, and nearly all have reared two broods each. The last only left me on the 17th inst., and, as is their custom, disappeared at once on leaving their nest. My swallows have numbered five pairs, and each pair reared two broods of about five each.

The first fieldfare of the season was here on the 26th of October; the redwings arrived on the 8th of October. Bullfinches are now catching readily in trap-cages, and a few cages in a locality would clear them out, or nearly so.—J. HAM, *The Wren's Nest, Astwood Bank*.

LEDBURY APPLE AND PEAR EXHIBITION.

It will be in the recollection of some of your readers that a few years ago a series of Apple and Pear exhibitions were inaugurated by the Woolhope Club, ending in 1883 in the publication in 1885 of that splendid work, "*The Herefordshire Pomona*." To these the successful Exhibition, which was held in Ledbury on Thursday 25th, in a spacious tent 300 feet long, erected in the beautiful park of Mr. Michael Biddulph, M.P., may be described as an opportune sequel, and surely never more so than at the present time, when there is so manifest an awakening among our horticulturists, as the leader in last week's *Journal of Horticulture* so clearly establishes. Ledbury, according to its programme, started its exhibition with the particular object of agitating for a local market for its fruit, yet the general interest to the public cannot be over-estimated when we see so small a town can stage 3000 plates of admirable specimens of Apples and Pears, and hold a conference afterwards at which the leading specialists of the day read papers.

Fittingly, then, as the prototype of many others throughout the kingdom, might the Ledbury spirited Exhibition be expanded into a Herefordshire Pomological Society on the lines of the Herefordshire Agricul-

tural Society, and, like that flourishing Association, be peripatetic, visiting by invitation each of its leading district towns, thus diffusing its influence through fresh centres and increasing its funds. If this idea were carried out in our own county, with her 29,000 orchard acres, and adopted by other counties, each association being affiliated to the Royal Horticultural Society, it would be impossible to be too sanguine as to the beneficial results. A new industry would be created, quite on a national basis. Not only the amateur and the big nurserymen, but the small market gardener, an over-done and unprofitable speculation—in the provinces, at least—and even the small allotment owner with the vexed two acres and a cow, would then pay his way.

But I shall be reminded that I am travelling beyond the record. Peas, as may be supposed in such a season as this, were far inferior to Apples in quantity and quality, still there were some fine specimens to be seen in most of the collections. For the most level lot (open), six varieties, though wanting in size and colour, were shown from the famous cordon wall at Holme Lacey by Mr. Denning, gardener to the Earl of Chesterfield. The most notable were Pitmaston Duchess, Beurré Boussoch, Beurré Bachelier, Hacon's Incomparable, Madame Treyve, Second prize, Mr. W. Wildsmith, gardener to Viscount Eversleigh, who had fine Beurré Diel and Beurré Hardy; third, Mr. W. Child, gardener to Earl of Coventry; highly commended, Mr. Ward, gardener to Lady Emily Foley, and Messrs. Bunyard; and commended, Rev. C. H. Bulmer. The heaviest Pears were in this last collection, five Van Mons Léon Leclerc, weighing over 4 lbs. Single plates of Pears, six varieties (open), Marie Louise, first Mr. Robert Smith, second Messrs. Bunyard, third Mr. Walter Child.

Dessert Apples, not exceeding twenty-four varieties, Messrs. Bunyard first; Messrs. Cranston second; Mr. John Watkins third. In the winning stand the best were—Brownlee's Russet, Sturmer Pippin, King of the Pippins, Dutch Mignonne, and Cardinal. These were a fine collection and well coloured, but as a whole too large for dessert size. Many think differently, however.

Culinary Apples, not exceeding twenty-five.—Messrs. Cranston first; Messrs. Bunyard second; Mr. John Watkin third. This was a grand class. Among the best shown were Beauty of Kent, good colour; Lord Derby, Cox's Pomona, Mère de Ménage, New Hawthornden (exquisite colour), and Ecklinville Seedling, grand here and everywhere; Blenheim Pippin (not good).

The vintage fruit (Apples and Pears) were very large classes, and shown very clean and well and correctly named. Mr. J. H. Arkwright held an informal conference of farmers and cider merchants to agree on an outline of rules to lay before the Council of the R.A.S.E., on the subject of the prizes they propose to give for the best exhibits of cider and perry at their jubilee meeting next year at Windsor.

A conference of fruit growers was held during the afternoon, under the presidency of Mr. Michael Biddulph, M.P., when excellent papers were read by Mr. S. Rawson, fruiterer and salesman, Birmingham, on "Fruit Growing and Distribution;" Mr. D. Tallerman, on the subject, "What Ledbury Fruit Growers May Do;" and last, but not least, by Mr. W. Coleman, on "Profitable Fruit Culture in Herefordshire." All the papers were listened to with the attention their great merits deserved.

The Rev. C. H. Bulmer of Credenhill, and Mr. G. H. Piper of Ledbury, judged the cider and perry fruit; Mr. Miles (Wycombe Abbey), Mr. Coleman (Eastnor), Mr. Crump (Madresfield), and Mr. Spencer (Goodrich Court) judged the dessert and culinary fruit; and Mr. Woolway of Bristol judged the cider.

The exhibitors who were present gladly acceded to Mr. Biddulph's suggestion that a choice selection from the best exhibits should be formed, and forwarded to Balmoral for presentation to Her Majesty the Queen.—THE HEREFORDSHIRE INCUMBENT.

DEVONSHIRE POMOLOGICAL SOCIETY.

OCTOBER 25TH AND 26TH.

At one time it was very doubtful if the Society would be able to hold its annual Apple and Pear Show, many of the growers who usually compete not having fruit sufficiently good to uphold their well merited reputation as cultivators. The Committee, however, and the energetic and courteous Honorary Secretary, Mr. J. T. Pengelly, had every reason to be well satisfied with the results of their labours. At the opening of the Show Sir Thomas Ackland, Bart., spoke at some length upon the benefits conferred by such exhibitions, and dwelt upon the efforts that are now being made to popularise hardy fruit culture. Sir Stafford Northcote and other gentlemen followed in a similar strain, and in all probability a still more instructive meeting or conference will be held next autumn. On the whole the Devonians have every reason to be proud of their achievements in Apple and Pear culture, as they fairly held their own against all comers. The Kentish Apples appeared to be more fully developed than the locally grown fruit, and it was generally thought some of them were grown under glass. There was no rule to exclude such, but they ought not to be mixed with open air fruit if the selections of the latter are to be of an instructive character. There were four lots of twenty-four culinary varieties of Apples staged, and with these Messrs. G. Bunyard & Co. were well first, having remarkably fine dishes of the leading sorts. The second prize was awarded to Mr. C. G. Selater, Devon Nurseries. Mr. D. C. Powell, Powderham, took the third prize for a highly creditable collection. With twelve culinary varieties Mr. D. C. Powell was first, his well selected collection consist-

ing of Gravenstein, Ecklinville, Blenheim Pippin, Mère de Ménage, Small's Admirable, Warner's King (very fine), Golden Noble, Brabant Bellefleur, Lord Derby, and Peasgood's Nonesuch, all large, clean, and even in size. Messrs. G. Bunyard & Co. followed closely, Emperor Alexander, Lord Suffield, and The Queen being the best dishes included in a generally good collection. Mr. C. J. Selater was third, and three other creditable collections were staged. In the open class for twelve varieties of dessert Apples Mr. C. G. Selater took the lead, having capital dishes of King of the Pippins, Blenheim Orange, Worcester Pearmain, Braddick's Nonpareil, Cornish Aromatic, Beauty of Wilts, Autumn Pearmain, Bibston Pippin, Gravenstein, Court Pendu Plat, and Cornish Gilliflower. Mr. D. C. Powell had an equally good selection, and was only two or three points behind. Among his were pretty dishes of Baumann's Reinette, Gravenstein, Blenheim Pippin, and Rosemary Russet. Mr. Berwick, Sidmouth, was third, and there were three other creditable collections shown. There were seven entries in a class for twelve varieties confined to private growers. Mr. R. Yeo, gardener to R. B. James, Esq., was first, his best being pretty dishes of Counsellor, Worcester Pearmain, Ribston Pippin, and Blenheim Pippin, the rest being culinary varieties. The second prize was awarded to Mr. J. Garland, gardener to Sir T. D. Ackland, Bart., his collection including very good dishes of Striped Beefing, Winter Hawthornden, and Emperor Alexander. Mr. A. C. Williams, gardener to W. C. Sim, Esq., was a good third. For nine culinary varieties Mr. R. Yeo was first: Mr. J. T. Baker, gardener to Mrs. Rowe, second; and Mr. H. Hill third. Mr. A. C. Williams staged very good dessert Apples in nine varieties, and was first, the second prize going to Mr. H. Hill, and the third to Mr. J. Garland. The last named had a remarkably handsome dish of the American Mother. With nine mixed varieties Mr. E. Protheroe was first, his best being Bramley's Seedling, Adams' Pearmain, and Peasgood's Nonesuch. Mr. W. Mortimer, gardener to Col. White Thompson, was a good second, and Mr. T. Westlake third. Classes were provided for single dishes of Peasgood's Nonesuch, Alfriston, Blenheim Pippin, Dumelow's Seedling or Wellington, Golden Noble, Mère de Ménage, Warner's King, Adams' Pearmain, Cornish Gilliflower, Cox's Orange Pippin, King of the Pippins, Margil, Ribston Pippin, any other culinary, and any other dessert varieties, which attracted numerous entries. In these Messrs. Bunyard & Son gained three first and six second prizes, Messrs. A. Truman, A. C. Williams (who had four first and two second prizes), W. Blackmore, B. Brown, S. Hodges, and J. H. Mounsdon, gardener to F. Bradshaw, Esq., also being successful. In the class for any other dessert variety Messrs. Bunyard & Son won the first prize with a handsome dish of Washington, which proved to be very crisp, juicy, and sweet. The first prize in a corresponding class for a culinary variety, Mr. S. Hodges was first for a fine dish of Loddington. Messrs. Bunyard and Son were the only exhibitors of three dessert varieties introduced since 1876, these consisting of Wealthy, Okera, and an unnamed variety. They were also first for three culinary varieties, these consisting of Bismarck, Belle Pouloise, and Royal Jubilee, all of which were of good size and attractive in appearance.

The competition was less keen with Pears generally, but many extra fine dishes were staged. Size rather than quality appeared in several instances to have most weight with the Judges, and the awards were rather severely criticised accordingly. Messrs. G. Bunyard & Son were awarded the first prize for a collection of twelve varieties, these consisting of Pitmaston Duchess, Durondeau, Doyenné du Comice, Beurré Superfin, Beurré Hardy, Maréchal de Cour, Beurré Rance, General Todleben, Beurré Clairgeau, Catillac, Grosse Callebasse, and Vicar of Winkfield, all extra large and even in size. Mr. C. J. Selater followed, his best being Pitmaston Duchess, Beurré Diel, Louise Bonne of Jersey, and Marie Louise, while the third prize went to Mr. D. C. Powell, who had a capital selection, all well-grown dessert varieties, amongst which the most noteworthy were Pitmaston Duchess, Glou Moreceau, Marie Louise, and Beurré Bachelier. The best six dishes were staged by Mr. H. Berwick, Sidmouth. Mr. C. J. Selater was a good second, and Mr. A. Truman third. There were seven entries in the class for three varieties, and with these Mr. D. C. Powell was well first, having fine, cleanly grown well-ripened fruit of Beurré Superfin, Marie Louise, and Muir Fowl's Egg. Mr. J. Garland was second, and Mr. J. H. Mounsdon third, the last named experiencing rather hard treatment. Messrs. J. Bunyard & Co. were the only exhibitors of three varieties of stewing Pears, and were awarded the first prize for five dishes of Beurré Clairgeau, Verulam, and General Todleben. Mr. Truman was first and Mr. C. D. Powell second for Catillac; and for any other culinary variety Mr. H. Berwick was first, staging a fine highly coloured dish of Beurré Clairgeau. Messrs. Bunyard were first and Mr. D. C. Powell second for Beurré Diel, both having good fruit. Many extra good dishes of Marie Louise were shown, and with these Mr. R. Smith, gardener to Lady Frances Fletcher, was first and Mr. Powell second. Doyenné du Comice also appears to be a favourite, and was well shown. Mr. A. C. Williams was first and Mr. Keliard, gardener to W. J. Battishill, Esq., second. Messrs. Bunyard had the best dish of Josephine de Malines, Mr. J. Garland being a good second. The best dish of Louise Bonne of Jersey was staged by Mr. W. Turner, gardener to H. W. Sanders, Esq., the second prize going to Messrs. G. Bunyard and Son. Mr. J. H. Mounsdon had a first prize for a good dish of Easter Beurré. Pitmaston Duchess was numerous shown, many of the dishes being extra heavy and well ripened. Mr. R. Dark, gardener to J. M. Miller, Esq., Barnstaple, was first, and Mr. A. C. Williams second. Mr. R. Smith was first for Winter Nelis, and Mr. J. Blackmore, gardener to C. T. D. Ackland, Esq., M.P., second, both having very good dishes of this popular variety. The best dish of Beurré Superfin was

staged by Mr. R. Dark, the second prize going to Mr. D. C. Powell. In the class for any other dessert variety Mr. R. Dark was placed first for immense fruit of Souvenir du Congrès, each of which must have been upwards of 1 lb. in weight, and were said to have been grown against an open wall. Mr. R. Smith was second with good fruit of Doyenné Boussoch. Mr. D. C. Powell was first for Medlars, Messrs. Bunyard & Co. for Quinces, and Mr. B. Brown for Tomatoes.

The non-competitors' collections were numerous and extensive, and added largely to the success attending the general display. Messrs. R. Veitch & Co., Royal Nurseries, Exeter, lent a great number of decorative plants, and arranged much the finest collection of Apples and Pears. Of Apples they had about 100 varieties, among these being very good dishes of Bismarck, Lane's Prince Albert, Gravenstein, Blenheim Orange, Cellini, Peasgood's Nonesuch, Sandringham, Lady Henniker, Worcester Pearmain, Ecklinville, Winter Hawthornden, Grand Sultan, Tibbett's Incomparable, Bramley's Seedling, and Niton House. Of Pears there were fifty dishes, the best being Flemish Beauty, Brockworth Park, Marie Louise, Beurré Bachelier, Pitmaston Duchess, Glou Moreceau, Louise Bonne of Jersey, and Doyenné du Comice. Mr. D. C. Powell staged a large collection of Apples and Pears, all of which were well grown, the selection also being trustworthy. Messrs. Bunyard & Co., Mr. C. G. Selater, and Messrs. Lucombe, Pine & Co. also had good exhibitions of Apples and Pears. Local fruiterers arranged a remarkably fine display of Jersey Pears, these including numerous boxes of Glou Moreceau, Easter Beurré, Chaumontel, Belle de Jersey, and other extra large fruit. It should be added the Exhibition was held in Fore Street Market Hall, this being gaily decorated and illuminated for the occasion in a most effective manner by active members of the Committee.

HARDY FRUIT GARDEN.

WHEN TO GATHER APPLES AND PEARS.—It is unwise to have a fixed time for gathering these, as it is possible to leave the fruit of some varieties too long on the trees, or what is still more reprehensible, it may be gathered before it is fit. When left on the trees till ready to drop off at the least touch, a heavy wind may quickly clear the trees and spoil the greater portion of the fruit. Even if it is gathered only just in time, it not unfrequently happens that the quality is impaired by remaining too long on the trees, and a dry mealy fruit be the result, this being more especially the case with Pears. Should the fruit be gathered when it has to be dragged from the trees, the chances are the greater portion will become shrivelled and tough, losing greatly in value accordingly. As yet very few Pears have been gathered by experienced growers in the southern counties, and still fewer Apples. Nor should they be till it is found that the seeds are nearly or quite brown, another good test being that of raising the fruit out of its natural position. If unfit to gather they will cling to the tree, but if sufficiently ripe will part readily. The latter test is to be preferred for choice Pears, every fruit of which is of value. Severe frosts will sometimes injure the latest fruit, but these are not to be feared during October at any rate, those recently experienced, though severe, only serving to hasten ripening.

STORING PEARS.—Such comparatively early varieties as Williams' Bon Chrétien, Clapp's Favourite, Beurré Giffard, and Souvenir du Congrès, will have been gathered in most warm localities, but in all cases are not yet used up. It is a good plan to gather these or any variety that keeps badly or which it is desirable to prolong in season as much as possible at intervals of about a week, those first picked being forwarded in gentle heat. In all probability a great majority of varieties will require this assistance before they will become fit to eat, and in this case their season will be prolonged considerably. A portion of the crops of Beurré d'Amanlis, Pitmaston Duchess, Beurré Superfin, Fondante d'Automne, Autumn Bergamot, Beurré Hardy, Louise Bonne of Jersey, and Brown Beurré will in most warm localities have been fit to gather early in October, but all of these are much later than usual, and the bulk will not be stored before the end of the month. Very late also are Marie Louise, Urbaniste, Doyenné du Comice, Doyenné Boussoch, Maréchal de Cour, Beurré Diel, Gansel's Bergamot, Beurré Bose, and other varieties usually gathered at this date (October 12th), and largely used in October and November, while the later Beurré Clairgeau, Thompson's, Van Mons Léon Leclerc, Huyshe's Prince Consort, Huyshe's Prince of Wales, Chaumontel, General Todleben, and Ilacón's Incomparable still cling closely to the trees. All these promise to ripen eventually, but such extra late varieties as Glou Moreceau, Josephine de Malines, Beurré d'Arenburg, Beurré Bachelier, Winter Nelis, Beurré Sterckmans, Easter Beurré, and Nec Plus Meuris are still swelling, and it is doubtful if these will ever mature properly. Pears may either be stored in a single layer with their stalks uppermost on ordinary fruit-room shelves, or they may be carefully packed in drawers, these being left open for a few days or till such times as the fruit ceases to evaporate much moisture. Everything about them should be clean and sweet, and the fruit ought to be protected from currents of cold air and severe frosts when necessary.

APPLES.—Beauty of Bath, Irish Peach, Quarrenden, and Summer Golden Pippin remained in season much longer than usual, and on the whole were good in quality. Kerry Pippin is now available, and a few King of the Pippins have been ripened artificially. Among culinary varieties Lord Suffield, Keswick and Carlisle Codlins, and Stirling Castle have done good service, and promise to keep well. The bulk of these are now fit for storing, and the invaluable Ecklinville should also be ready to gather. All these will keep fairly well, but the Duchess of Oldenburgh, another sure cropper, loses in weight and quality by being stored. Emperor Alexander, Cox's Pomona, Lord Grosvenor, Flower of Kent, Hollandbury, Lane's Prince Albert, Blenheim Pippin, Tower of Glamis, Lemon Pippin, Alfriston, and a few other good culinary varieties will be very late this year, all at present having quite white pips or seeds. It may now be found safe in some localities to gather a portion of King of the Pippins, Cox's Orange Pippin, Adam's Pearmain, Braddick's Nonpareil, Ross Nonpareil, Margil, Claygate Pearmain, Lord Burghley, and Blenheim Pippin, but in rather late districts very few of these are yet fit to store. All may eventually be stored in thin layers on fruit-room shelves, but will keep equally well, perhaps better, when fairly large heaps are formed. The less valuable orchard-grown fruit can be kept well in large heaps in outhouses or sheds, but they must be well protected from frosts. If spare rooms are utilised for the storage of Apples these should be covered with paper, this excluding frost, which will otherwise find its way up the crevices, even better than straw, and does not taint the fruit as does the straw. Paper is also the best protective material. In any case it is very unwise to store bruised or unsound fruit, and all should therefore be handled and sorted over carefully, and those damaged in any way kept apart from the rest for immediate use.

SIMPLE AND GOOD METHOD OF STORING APPLES.—In many gardens there exists a collection of Apples, and no adequate provision made for storing the produce. Very frequently the crops are comparatively small, or, say, do not exceed a bushel of each variety. The best course to pursue with these is to gather and store each variety separately in quite clean boxes, which may be bought or made at a trifling cost. None but quite sound fruit are suitable for this method of storing Apples, and these should be carefully gathered and stored, no matter how many layers deep, direct in the boxes or barrels used as a good substitute for the latter. The lids to be then put on and all be set in a dry room or outhouse, and protected from severe frosts when necessary. Apples thus stored must not be muddled about in any way, and if left alone will keep surprisingly well, their season being prolonged longer than by any other ordinary method of storing yet tried. Large heaps of orchard-grown fruit may be formed in the open, where they will keep admirably. The only essentials are careful handling and sorting over of the fruit, a well drained position, and a good covering of clean straw with an outer casing of soil. Funnels formed, either with drainage pipes or a wisp of straw, should be set on the ridge of the heap by way of an outlet for any moist heat generated by the fruit.

FRUIT FORCING.

VINES.—*Early-forced Vines in Pots.*—Where thin-skinned Grapes are required in April, they taking precedence of Lady Downe's and other late varieties, the house intended for their culture will now be ready for their reception, if indeed they are not already in position. The pots should be placed on stands or pedestals which will not give way under their weight or interfere with turning the fermenting materials used for supplying bottom heat, than which nothing answers better than bricks placed to the required height without mortar. Where weight and quality of crop are first considerations some turf should be packed against the pedestal, and the holes in the pots enlarged, bringing the turf up above these so as to be within easy reach of the roots, which will speedily follow the stimulating food with which the Vines are fed. For supplying bottom heat Oak leaves are the best, as they supply heat and moisture through the early stages of growth and rich stimulating food from their decay at the finish, when the fruit requires all the support that can be given. Take care that the heat about the pots does not exceed 70° to 75°. The canes should be allowed to fall in a horizontal position over the fermenting material until they have broken, and be syringed two or more times a day, but sufficiently early for the last time each day to allow of the canes becoming fairly dry before nightfall. If the Vines have not been shortened to the proper length and dressed with styptic they must not be shortened now, as bleeding would weaken them, and it is easy to disbud when they start. Black Hamburgh, Royal Ascot, White Frontignan, and Foster's Seedling are excellent kinds for early forcing in pots, to which may be added Madresfield Court, which requires liberal feeding until the berries show signs of changing colour, when a gradual diminution, combined with a dry atmosphere, is necessary to prevent cracking.

Earliest-forced Planted-out Vines.—The houses containing Vines from which ripe Grapes are expected early in May should be closed by the middle of the month, or if the Vines are young and vigorous and not subjected to early forcing before close the house at once, as they do not break so quickly as old ones that have been forced for a number of years. With a view of economising fire heat and to produce a humid atmosphere a good bed or ridge of fermenting materials, consisting of two parts leaves and one of stable litter, may be placed upon the border and turned at short intervals, additions being made as the heat declines. In the canes of old rods they may be tied up to the wires as soon as they are dressed, but young canes ought to be suspended in a horizontal position over the fermenting materials, where they can be well syringed with tepid water slightly warmer than the house, but it is well to allow

them to become dry at least once in the twenty-four hours or at night. Keep the temperature at 50° to 55° at night and 65° on fine days, the temperature by artificial means in the day being 55° until the Vines begin to move. If the border is not in a thoroughly moist condition it must receive repeated supplies of tepid water, or liquid manure if the Vines are weak, so as to thoroughly moisten it through.

Succession Houses.—Push on the pruning as soon as the Vines become clear of foliage, also the cleansing, painting, and limewashing, carefully washing the Vines with soap and water prior to dressing with an approved insecticide. Presuming the Vines have been fairly free of insects, avoid the old-fashioned practice of peeling, scraping, and painting with a pigment of clay, soot, sulphur, and other substances, which is more calculated to protect the larvæ than destroy it; it is better to wash twice and preserve the bark, which is of incalculable value in holding moisture from the syringe, and aids the flow of the sap when they are starting in growth when excited by genial moisture and warmth.

Midseason Houses.—Those that still contain a few Grapes, Black Hamburghs or other thin-skinned varieties, may now be cleared, as the fruit will keep fresh in a cool dry room, and the Vines will derive great benefit from free exposure to the weather so long as it continues dry and mild. When thoroughly at rest Vines will not be injured by a little frost, but a sudden chill should be guarded against by drawing up the roof lights or closing the houses when the nights are likely to be wet or frosty. The Grapes should be cut with all the wood that can be spared for insertion into bottles of water, which should be soft, and a piece of charcoal placed in each, removing the old foliage, but do not shorten the wood that has been allowed to extend beyond the bunch. The Vines should have the laterals shortened or removed, and the growths generally cut back, so as to plump the buds, but it must be done gradually, particularly in the case of vigorous Vines which are disposed to make late growth, which should be checked by free ventilation constantly, turning on the heat by day, but shutting it off at night, only the temperature must not be allowed to fall below 50° at night, until the foliage affords indications of falling.

Late Hamburghs.—The atmosphere in which bunches of these are hanging cannot be kept too dry, only the temperature must not be too high or the Grapes will shrivel no matter how moist the border. A steady temperature of 50°, with a little warmth in the pipes and liberal ventilation on dry days, will suit them during the fall of the leaf, when, unless the houses are well adapted for keeping them, the bunches may be cut, bottled, and placed in the late houses.

Late Houses.—If late Grapes have not finished (and the glorious weather of September and October was truly a godsend) nothing will be gained by pushing the fires after the wood is ripe, as a high temperature now will not prevent the Grapes shrivelling nor when the leaves fall. Perhaps the most crucial test of the thorough maturity of Grapes is evidenced by Mrs. Pince, it being sure to shrivel if the Vines have not heat enough at the right time—i.e., from the fruit stoning until the berries are thoroughly ripened to the shank. Well done it is one of the very best late Grapes for quality, but it has not done well this season with us. Where immaturity and consequently shrivelling is the result of overcropping, relief should be given the Vines by cutting a portion of the bunches at the earliest convenience, but where it can be traced to imperfect drainage or bad borders no time should be lost in getting out the old soil and laying the roots in new compost over rectified drainage. Highly finished Muscats hanging on Vines that have lost their leaves are liable to be tinged by exposure to bright sunshine, which, though weak in November, disfigures them to some extent, especially when grown for market. To guard against this, which is only needed in case of houses with large panes of glass, a single thickness of pilchard nets drawn over the roof will be a sufficient shading. If not already done Vine borders should have some covering placed over them that will throw off rain and snow. The inside borders will be getting dry at the surface, and should be covered with some dry fern or straw neatly spread over them, which will prevent the border cracking and its giving off dust, besides improving their appearance. Give daily attention to the removal of ripe foliage as it parts from the Vines, keeping the houses cool, dry, clear of plants requiring water, and thoroughly clean.

CHERRY HOUSE.—The lights having been taken off the house, the trees having cast their leaves in doing so, and as soon as all are down prune at once. Cut back to within an inch of the base from the shoots started all those laterals which were made during the summer, and which have been stopped at about the fifth joint. It is not good practice to shorten any of the terminal shoots unless the trees have reached the extremity of the trellis, or when it is necessary to multiply the shoots another season. The trees should then be washed with a brush with soap and water, and may then have the branches tied together to save them from injury whilst the house is being cleansed and the walls limewashed. The latter should be made of the best fresh lime applied rather thinly, and is best with a little size to make it adhere firmly. Dress the trees then with an insecticide, train and tie them to the trellis. These matters being attended to all the loose material on the border should be cleared off, and any soil of an inert character that can be forked over and changed for fresh turfy loam of a calcareous nature or a sixth of lime rubbish may be added, then top-dress with 3 inches of partially decayed lumpy manure. If the borders are in the least dry they must have a thorough supply of water, but the lights having been off it will be necessary only in exceptional cases. Keep the house fully ventilated at all times excepting during frost until such time as forcing operations are commenced, which, to have the fruit ripe at the beginning of May, will need to be at the beginning of December.

KITCHEN GARDEN.

WINTER RADISHES.—In many cases it is a difficult matter to keep up a supply of Cucumbers, Lettuces, Endive, and other salad plants throughout the winter, but Radishes may be secured by all, and a few, when gathered daily, always give satisfaction. At present we are gathering the Red Globe in good condition. It will last into November, and the China Rose will then come in. The former are swelling freely, and therefore the last sowing made three weeks ago will be ready about January; but, as a rule, all Radish seed is sown too thickly. They come crowded, and the tops screen the roots so much that instead of bulbing they only remain thin and unfit for use. They will do this in summer, but they are more inclined to it in autumn and winter, and the rows or bed should be thinned before the plants injure each other. Every plant ought to stand clear of its neighbour, and when this arrangement is carried out in good time each one may be sent to table.

PROTECTORS.—Of late the weather has been excellent, but a severe frost may occur any time in November, and all should be prepared for this. See that a good supply of covering material is convenient to be used at an hour's notice. Bracken is our favourite protector for ground covering, and we often place it over framelights and handlights as well. We cut several waggonsloads of it in the park, and store it in an open shed when it is dry, and we find it invaluable before the winter is over. When it is spread over the crowns of Salsafy, Parsnips, Radish, and Celery, it prevents the frost penetrating the soil and preserves the vegetation. Mats are also useful in this way, but only old ones should be used for ground covering, as the wet soon causes good mats to decay. They do not suffer so much on frames, and as a substitute for them we have had some light hurdles made and filled with drawn straw. These keep out a great deal of frost. Ashes keep the frost out of the soil remarkably well, and if a layer is spread along each side of the rows of any kind of roots the frost will not readily penetrate to them.

STORED ONIONS.—These are not keeping so well as in some former years. Some which appeared to be quite matured and likely to keep for many months have sprouted at the top. This is particularly the case with those that are thick in the neck, and as their growing produces a certain amount of moisture in the heaps the whole should be turned, and every one that shows any disposition to grow taken out. Spread the sound ones well out and admit abundance of air.

CAULIFLOWER.—As is usual at this season Veitch's Autumn Giant is heading excellently at present. As an autumn Cauliflower it is unique, but we find it turns in more quickly than it can be used, and as this may not be the case long, as a severe frost may check them, the surplus heads should be preserved. We have saved them from a slight frost for many days by half breaking some of the large leaves and turning them over the heads, but this does not check their developing, and when full grown or of good size the best way is to cut them with a good piece of the stem attached, trim the bulk of the leaves off and insert them in boxes of damp sand, leaf soil, or ashes in a semi-dark place where they will be cool but free from excessive damp, where they will remain good for three or four weeks. Care must now be taken that young Cauliflowers, plants in frames and handlights are not caught by the frost. Protect them at night when necessary, but do not be afraid to admit abundance of air to them on all favourable opportunities.

STORING CARROTS.—At one time in the growing season, about July, our main crop of Carrots showed indications of being attacked by grubs, but a sprinkling of lime from the gasworks was at once thrown over and soon washed in by the rain, and at the present time this crop is one of the finest we have ever had to store. They are large, well formed, and bear very slight traces of having come in contact with worms, and generally Carrots are good this season; but they should not be left much longer in the ground, as when rain saturates the soil it may cause many of them to make a second growth, and then the best of the roots will split. This should be avoided by lifting them at once, rubbing the bulk of the soil from the roots, and cutting the stems away. They should then be stored in sand or ashes, where they will be sheltered from wet and frost. As a rule we store them with their crowns projecting outwards, and when any show signs of growing the young growths can readily be brushed off. Late grown Carrots that are not fully grown now may be left in the ground and drawn as required, as they will not be harmed by the weather.

PARSLEY.—A supply of this should be kept in hand for the winter. It is in daily demand, and its failure is as much felt as any crop we know. Where the plants have grown luxuriantly many of the first formed leaves have become brown, and the whole of these should be cut off, washed clean of grit, and then dried. If hung up in bunches in the kitchen, or broken and put in wide-mouthed bottles, it will be found of much use throughout the winter for seasoning. Let the growths that remain on the plants be well exposed to keep them hardy, and should severe frost set in cover them with bracken, mats, or glass lights. Where there is a good little bed it is often convenient to place a frame quite over it. Should it be necessary to grow Parsley plants in pots they must be kept in a cool house or frame, as a close warm atmosphere does not suit them.

KIDNEY BEANS.—Both the Dwarfs and Runners in the open are quite over, and many of them were destroyed before they had finished flowering; but those under glass are growing freely, and they should be syringed on fine days, and the temperature in which they are growing should not fall below 65°. When grown in a low temperature at this season they are apt to assume a scraggy habit, from which it will be difficult to force them later on.

PLANT HOUSES.

Gardenias.—Cuttings that are rooted may be placed in 3-inch pots, in which they will make useful little plants for a good start early in the year. Pinch the shoots as they grow to induce them to branch. Cuttings may still be inserted, by which a considerable gain is effected over propagating in spring. When rooted grow them in an ordinary stove temperature. If gentle bottom heat can be provided all the better; this is not really necessary. Place the earliest plants in brisk heat and they will quickly swell their flower buds. The latest will do in a temperature of 55°; they are easier and more safely retarded now than when their flower buds have commenced swelling.

Leoras.—Cuttings that are well rooted in thumb pots may be placed into 3-inch pots, in which they may be allowed to produce one good truss, or they can be pinched to induce them to produce two or more. If the latter it will be necessary to place them in 5-inch pots when they have filled the others with roots. Water these carefully as well as established plants, and do not administer water that is of a lower temperature than the house in which they are growing. Arrange the plants rather close to the glass, so that they can enjoy abundance of light to harden and ripen their wood.

Coleuses.—Keep these in a temperature of 60°, and insert cuttings in small pots at intervals of a few weeks where highly coloured little plants are appreciated for decoration. Cuttings should be rooted for this purpose in 2-inch pots; they will root freely enough on a shelf in a temperature of 60° to 65°. For this purpose only highly coloured varieties should be grown, and the cuttings should be strong and well furnished with large leaves at the base. They are ready for use directly they are thoroughly rooted, which saves time over inserting small cuttings, and then having to grow them on until fine foliage is developed.

Tradescantias.—Cuttings of the variegated forms of these should be inserted thickly together in 2 and 3-inch pots directly the stock plants have shoots long enough. These root freely in any warm moist position. Few plants look better than these when used with Mosses and small Ferns on the dinner table or any other position in which plants of this nature can be employed. The plants should never exceed 5 inches in height, therefore it is necessary to strike some every few weeks. Our stock plants are from cuttings inserted thickly in boxes, and for many purposes plants raised in boxes and lifted out will be found very useful.

Euphorbia jacquiniæflora.—Plants that are in a backward state of growth should not be kept too warm, or they will continue to grow and fail to flower satisfactorily. Expose them to full light close to the glass, and admit air daily when the weather will allow of this being done. The night temperature should not exceed 55°, which will bring the growth to a standstill. The wood will harden and flowers in plenty will be the result.

Centropogon Lucyanus.—Keep these plants in a temperature of 55° at night, and give air daily when the weather is mild. They are most effective for grouping when allowed to carry one or two good shoots only in 4 or 5-inch pots. These can then be so arranged when in flower that the flowering portion of their shoots will stand or arch well above surrounding objects. Plants with a number of shoots have a heavy appearance, and are too stiff and formal when trained round stakes.

THE BEE-KEEPER.

SECTIONS.

I AM sending you to-day, per parcel post, one of my new glass sections I have mentioned previously, filled and finished off by my stock of Punie bees between October 15th and 27th. This section is not up to the mark, as these bees soil their combs with propolis, or, in fact, anything sticky; still, it is better than I expected, and I consider very passable; in fact, I saw much worse at Nottingham Show with prize tickets attached. You will see that this section is not ornamented with anything; it is sufficiently beautiful in itself without any other manipulation.

Anticipating the inquiries as to what these sections will cost, allow me to state that I intend by drawings and instructions to put it in the way of every bee-keeper to make his own by the fireside in winter time with tools that will not cost more than 2s., and if he requires help and has any children over eight years of age he can let them make the sections just for amusement. If he prefers to buy them I think plenty will be glad to sell him a thousand ready cut for 10s. As for putting together, they can be done much quicker than wooden ones. Then see, too, how all stains and propolis can be cleaned off, crated, and sent to market in a style that no one can resist buying.

A noted authority recently said that glass was a most unsuitable substance to make sections of. Does this one look as if it was? I hope to show that glass is the best substance we have for sections, and wood one of the worst. In glass, the bees, as will be seen, readily fill up the cells next to it, as the walls are equal to wax ones for holding honey. In wood, instinct teaches them that it will absorb the liquid honey and so cause the combs to detach from

its sides, so they always leave a row of empty cells all round till the last; nor do they fill them until they have well waxed the wooden sides. To hide these defects, a host of contrivances have been brought out, many of which are patented.—A HALLAMSHIRE BEE-KEEPER.

[The section referred to arrived quite safely, the glass being made secure in position by fine wire, and the whole well packed in a wood box. The section is, as represented, well filled, neat, and even tempting in appearance. Obviously any person who can use a glass cutter can make sections of this kind and put them together quickly. Our correspondent should send samples to "A Lanarkshire Bee-keeper" and "Felix." They can be forwarded through this office if desired.]

BEES AS EDUCATORS.

EDUCATED EYES.

No sooner does a person become the owner of a colony of bees than he looks around to see what are the prospects of future gain. Heretofore he drove or rode along the highways, noticing the ruts, bridges, fences, and houses, but now his vision takes in a wider range. His observation is quickened, and trees, shrubs and plants have put on new life, as it were, to his enlivened faculties. From the first opening buds in spring until the last rustling leaf has fallen his interest never lags, as he constantly watches the opening flowers, and notes with pleasure the busy workers roaming over them in quest of treasure to storse in their hives.

NECTAR IN WEEDS.

What was to him once a useless weed, to be cut down with the scythe or whacked off with a hoe, is clothed in beauty, and becomes a priceless treasure. Whoever saw any beauty in the Figwort, or watched for the appearance of its tiny cupboard, looked down into their depths for the first appearance of sparkling nectar, but a bee-keeper? Or whoever saw any utility in Spanish Needles or Beggar-ticks? There is a bond of friendship existing between the bee-keeper and nectar-bearing plants, and they appear to spring up to greet him wherever he goes. The Indian calls White Clover "the White Man's Foot," and well he may, for its modest flower soon appears as the harbinger of peace and plenty.

SOILS.

The interest thus awakened in plants soon takes on a wider range, and extends to the soil. Seeds of Sweet Clover (*Melilot*) are scattered on gravelly soil, take root, penetrating deeply, keep it from washing and drying and add to its fertility. Dreary wastes thus become clothed with verdure, adding to the beauty of the landscape and yielding choice nectar, fit food for gods. On a recent trip of a dozen miles on the railroad we were agreeably surprised to find this plant growing luxuriantly nearly the whole distance, and some deep cuts were so covered with it that the soil could not be seen. It is to be hoped that the officers of railroads will appreciate the utility of this plant in keeping the soil from washing away and prevent damage and danger thereby, and foster its growth. I have seen the yellow variety of this plant growing on the borders of salt marshes on the shores of Long Island Sound.

MOISTURE.

Marshes and wet lands along rivers and watercourses come in for a share of attention by the bee-keeper. His eye quickly detects anything in the interest of his winged stock. If by digging a ditch and running off water the growth of favourite bee plants is promoted, it is done. He then benefits his neighbours as well as himself, for as the ground becomes dry Blue Grass and the Clovers will take root, thus promoting grazing for stock, and malaria will disappear. New plants will spring up as if by magic, the Button-bush (*Cephalanthus occidentalis*) growing in water. It seems as if the seeds of honey plants rattled from the bee-keeper's clothes. The seed of many honey plants is food for birds, which are our friends and co-workers in destroying many noxious insects.

EDUCATED EARS.

As seeing is cultivated by bee culture, so is hearing—even all the senses are quickened much better than they can be in a kindergarten. How soon the trained ear discovers the note of the robber, the sound of swarming, the piping of queens, the happy hum of plenty, or the sorrowful moan when the queen is lost. The sense of smell reveals the blooming of Apples, as also the opening of the fragrant Bisswood, Buckwheat, &c., and reveals the presence of that terrible disease, foul brood.—MRS. L. HARRISON.—(*The Prairie Farmer*).

TRADE CATALOGUES RECEIVED.

Dicksons, Limited, Chester.—*Catalogues of Roses, Auriculas, Carnations, and other Florists' Flowers.*

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Cattleyas (*C. E. D.*).—The occurrence you notice is probably due to the strength of the plants. It is occasionally seen, but is not constant.

Dendrobiums (*Reader*).—A temperature not falling below 50° will suit the plants named until it is desired to start them for flowering. Let them have a sunny position, and very little water will be needed, only sufficient to prevent the growths shrivelling, and but little damping will be required on the paths—none in damp, cold weather. Water should be employed about the same temperature as the atmosphere of the house, and it is never wise to supply very cold water to plants grown under glass.

Pleiones (*Idem*).—They will flower well in the *Odontoglossum* or cool house, and the flowers last longer in a cool temperature than in a warm house, provided there is not too much moisture. The flower sent is *P. lagenaria*, and is one of the most free of the genus.

Areas of Glass Structures (*A Youngster*).—We have no record of the extent of ground covered with glass for growing fruit and flowers for market by different cultivators, therefore we cannot say whether Mr. Ladd's "glass area" is the most extensive or not. Possibly some of our readers may be able to give information on the subject. Our reply to your second question is, Write to the Curator, Royal Gardens, Kew.

Staging Chrysanthemums (*Inquirer*).—The regulation size of a stand for twelve blooms is 2 feet long, 18 inches wide, 6 inches high at the back, and 3 inches in the front. This you will find large enough if you elevate the Japanese blooms just sufficiently for the florets to show themselves in the best manner. A good deal depends on cupping the blooms, and on this and other details of staging you should study Mr. Molyneux's book, which can be had by post for 1s. 2d. from this office.

Land Improvement (*Justitia*).—Are you not somewhat late in your critique? You do not name the persons to whom you suggest credit is due—a somewhat singular omission under the circumstances. It is quite certain that our correspondent had no intention of conveying a wrong impression, and equally certain that such an idea as you indicate could not be entertained by regular readers of the Journal who have been made well acquainted by special announcements (that you can scarcely have seen) with the circumstances of the case.

Tanks for Rain Water (*Subscriber*).—The size of tanks must obviously be determined by the rainfall of the district, governed also by the probable withdrawal of water for domestic and other purposes. A tank 12 feet by 11 feet, and 5 feet deep, holds about 4000 gallons. An inch of rain on an acre is about 23,000 gallons, and from this, and the probable weekly withdrawals, you will be able to ascertain the extent of storage to provide. There is another way of arriving at the matter. Assuming the rainfall is 24 inches, and you double your area, you have the amount in cubic feet. But is your area correct? It is not the roof surface, but the area of ground that the roofs cover on which calculations should be based, or a great excess will be presented. This is all we can say in the absence of sufficient data on the subject.

Fruit Trees for a North Wall (*Planter*).—As the Currants are not wanted Plums and Cherries may be grown. Morello Cherries would be more certain to bear and ripen well than dessert sorts, though we have no doubt good fruit might be had from these. All except the latest Plums would answer. We have had good crops of Czar, Victoria, White Magnum Bonum, Prince Englebert, Kirke's, Pond's Seedling, and Purple Gage, from trees against a wall facing due north, the second-named bearing most heavily. We should prefer covering the wall with diagonal cordons, planted about 18 or 20 inches apart. The space would be covered much more quickly than with fan-shaped trees, and the former are inexpensive. When you decide which form of tree you intend planting we will name some good varieties if you wish, repeating the length of the wall and aspect, as your letter cannot be preserved.

Petroleum and Vines (*F. A.*).—You say you have pruned your Vines, and "dressed them with petroleum in a pure state as purchased," for the extirpation of the mealy bug, and now ask whether the petroleum will injure the buds. We occasionally receive a letter of this kind that

causes us some astonishment. Over and over again safe methods have been recommended for cleansing Vines, and for preparing petroleum for applying to them strong enough to destroy insects, yet without risk of injury to the buds. Yet you have done what we have not recommended, and run the risk of seriously injuring the Vines. We have known Vines killed by a too free application of petroleum, and others escape when the dressing has been light; and what the effect in your case may be no one can tell. We hope, however, you will be fortunate, though you have read carelessly and acted precipitately.

Current Trees Unfruitful (M. C. B.).—Young Currant bushes planted about five years ought now to be in a good state for bearing, but some gardeners have a plan of cutting the greater part of the shoots away annually, and with the shoots the crop of fruit they would bear the following season. Either that is your case or the buds have been taken by birds, for it is not possible to have Currant bushes five years unfruitful or with little fruit without something preventing. Root-pruning would certainly check the tendency to undue vigour, but it would be much better effected by allowing the bushes to bear fruit, which ought to be the case if the pruning knife be laid aside, merely using it to thin out overcrowded branches and remove irregularities of growth. We do not advise lifting, as it checks the growth and prevents the fruit swelling satisfactorily the year following. We presume the bushes have plenty of space, and are not shaded by trees or buildings.

Grubs Destroying Primulas (G. H.).—The grubs that we find with the plant are the larvæ of the destructive weevil, *Otiobryncus sulcatus*. If the soil is infested with them they will almost certainly injure the other plants, and if they have entered the stems it is doubtful if they can be prevented doing further injury. You might try the effects of petroleum at the rate of half a wineglassful to a gallon of water, well agitating when used, proceeding experimentally on a few plants at first. Possibly they might not be injured by a stronger mixture, which you could try on one or two. Another remedy worth trying is to procure 2 ozs. of white hellebore powder, beat into a creamy paste with boiling water, then mix in a gallon of cold water for use. If you carry out these suggestions we shall be obliged if you will favour us with the results. All soil containing larvæ or small worms should be roasted by subjecting it to heat equal to that of boiling water, then moistening before use. This increases its fertility rather than otherwise. Watch for and destroy all the weevils you can find in the spring. They are most voracious, and apparently almost omnivorous, feeding chiefly at night.

Grapes (W. Williamson).—The Alicante berry is very large, but not typical; we have occasionally seen one or two berries on a bunch similar to the one sent, and apparently as large, but we neither measured nor weighed, so cannot say whether they exceeded $\frac{1}{2}$ inches in circumference or 5 drachms 2 grains in weight. The berry is round, or rather somewhat flattened instead of tending to the oval in shape, and contained six good seeds, which is an unusual number for a Grape to produce. We have seen larger berries of Gros Colman, also much better in colour and quality than the one you send. The discolouration on the white Grapes sent is not the ordinary "rust." Has there not been a slight attack of mildew, of which there are not wanting signs on the Foster's Seedling? Perhaps you have been sulphuring the pipes and the fumes have been too strong. Specks at the tips of Muscat Grapes are often caused by the remains of the flowers adhering to them too long, this being induced by a fully too moist atmosphere. We suspect you have kept the house too moist at times, and occasionally there has been a rather heavy deposition of moisture on the berries. There has been some little error in management somewhere, but as you withhold details of management we are placed at an obvious disadvantage in determining the precise cause of the discolouration of the fruit.

Beds in Flower Garden (Weybridge).—All that can be done in this case is to advance a few suggestions, excluding to meet the conditions Zonal Pelargoniums. The central bed might be filled as follows:—A good plant of either *Ailanthus glandulosus*, *Aralia papyrifera*, *Arundo Donax variegata*, *Rhus glabra laciniata*, or a tall-growing *Ricinus*, the last named only being obtained from seed for the centre. Surround this with a broad band of Cannas, these being banded with either *Cineraria acanthifolia* or white *Marguerites*, a good edging of purple Beet completing the bed. Either of the tall fine-foliaged plants named would be very effective dotted among the Cannas, but it is only in extra large beds that such mixtures should be attempted. Another effective mixture for a large bed would consist of a central plant of *Ricinus sanguineus*, and at a good distance from this a ring of *Ricinus Gibsoni*. The groundwork or spaces between the *Ricinus*es to be filled in with either white or yellow *Marguerites* or single white *Dahlia alba*, the latter being kept pegged down. Next these may be planted a band of either dwarf variegated *Abutilons* or yellow *Calceolarias*, with an outer edging of *Iresine Herbsta* or dwarf Beet. Two of your half-circle beds might be filled with yellow *Calceolarias* or yellow *Violas*, mixed with and surrounded by *Iresines*, with a broad edging of either *Cineraria maritima* kept pegged down, *Centaurea candidissima*, or *Stachys lanata*. The other two half-circle beds could have a centre of *Heliotrope*, either mixed with or surrounded by a buff-coloured *Calceolaria* banded by a scarlet *Verbena*, with an outer edging, if the size of the beds permit, of *Alyssum maritimum*. The four outer beds also to be planted in pairs oppositely placed. Tuberous *Begonias* planted about 12 inches or rather less apart, the intervening spaces being filled with either dwarf blue *Lobelia* or *Mesembryanthemum cordifolium variegatum* with an edging of Golden *Pyrethrum*, would be effective and contrast

well with beds composed of *Chamaepeuce diaantha*, mixed with blue *Lobelia* and edged with *Alternanthera magnifica*. A rather pretty effect results from a mixture of early raised plants of East Lothian or earliest flowering autumn Stocks, and either *Gaillardia picta* or *Gaillardia Lorenziana* from seed, with an edging of dwarf *Ageratum*. Seedling *Verbenas* are suitable for the centres of dwarf beds, and a mixture of *Fuchsias* also takes well. We cannot give more definite advice without knowing what kinds of plants you have in stock or can raise or procure for the purpose in view.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*P. Keller*).—Doyenné du Comice. (*F. Smith*).—1, Beurré d'Amanlis; 2, Nouveau Poiteau. The cause of the cracking is the continuous wet summer. (*T. H.*).—1, Kerry Pippin; 2, Golden Pearmain; 3, Golden Noble. (*T. Stephens*).—1, Scarlet Nonpareil; 2, D'Arcy Spice; 4, Duck's Bill; 5, Allen's Everlasting; 6, Golden Reinette. (*J. H. H.*).—2, Maréchal de Cour; 3, Glou Morceau; 5, Vicar of Wiukfield; 6, Swan's Egg. (*Jno. Weaver*).—1, Alfriston; 2, Doubtful, perhaps an imperfect Blenheim Pippin.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Constant Subscriber*).—*Echinops ruthenicus*. (*G. Mantini*).—*Pleione Wallichiana*. (*R. O. and W. Bray*).—*Pleione lagenaria*. (*K. M.*).—Your questions cannot be answered this week. 1, *Begonia natalensis*; 2, *Begonia fuchsoides*; 3, *Tradescantia zebrina*; 4, *Adiantum ethiopicum*. (*Club Moor*).—A variety of *Scabiosa atropurpurea*. It is raised from seeds.

COVENT GARDEN MARKET.—OCTOBER 31ST.

ONE-SIDED FARMING.

RUSHING to extremes has been the characteristic of very much of the practice of many British farmers under the heavy cloud of depression which has been hanging over them of late years—we might say for the last decade, and we doubt not that many of them have had bitter reason to regret such action, for however desirable a change of the recognised system of cropping might appear for the moment, the result has almost invariably gone to show that the growth or non-growth of this or that crop affords no real or safe remedy for low prices. Take, for example, the Barley crop. In the great corn-growing district of East Anglia Barley has been turned to as the last resort of the corn-grower; and in what sort of position is the exclusive grower of Barley this year? We may turn to our own practice for an answer, for although we have all along continued growing a fair proportion of Wheat, yet we have tried to have full and fine crops of Barley. To achieve an end so palpably desirable, simply because it must certainly prove profitable if the grain could be matured and sowed in good order, we have spared no pains or expense in the process of cultivation and in obtaining good seed. But under the adverse influence of bad weather our best crops of Barley this year were beaten down by rain and wind; the grain is thick-skinned and discoloured, and it is only by the superior bulk of the crop that we can obtain a profit upon the sale of the low-priced grain. Sure enough our efforts are handicapped by the uncertainty of our fickle climate.

Well, we are wont to tell this to one another, perhaps with a sort of vague feeling that this uncertainty, this fickleness, is peculiar to our climate alone. But is it so? It may afford many a crumb of comfort to know that there are such things as drought and famine in India; of destructive frosts, drought, and excessive moisture in America. If proof is wanted, we have it at hand from one of these great corn-growing countries in the pages of a contemporary, which tells by the pen of a resident farmer in Canada West, of "the complete failure of the winter Wheat crop in Canada and many States of the Union—a failure aggregating many millions, not of bushels, but quarters. Since then the situation has been much intensified by the great spring Wheat crops of the Western States and Manitoba following suit owing to early frosts. In truth, early frosts at the end, late frosts at the beginning; a destructive drought in one section, and a super-abundance of moisture in another, have so curtailed and nibbled away our usually enormous Wheat crop, that, for export, only a mere modicum of it, as compared with year 1879-80, remains. This is no pessimistic exaggeration, but a simple matter of fact.

"Whilst the farmers of Eastern Ontario, their crops licked up by a burning sun and cloudless sky, were selling off their milch cows to Yankee speculators at from 36s. to 48s. per head, the inhabitants—French Canadians—of Quebec watched their crops rot upon the ground amid continued rainstorms, and the recent settler of Manitoba and Daotah, in somewhat ignorance or necessity, seeding late—aye, and old settlers seeding early too—beheld to his chagrin and bitter disappointment the complete destruction in some instances or severe injury in others of a most promising Wheat crop before the magic wand of the ice king." Tempted by the price of Wheat in this country the farmers of America have very generally been guilty of one-sided farming in growing Wheat to the exclusion of all other crops. For a while this answered well enough, but the inevitable reaction has set in, and many of them are practically ruined. Nor have they been alone in such mistaken practices. In

this country, to take one among several examples, we find some Hop-growers uprooting Hops by hundreds of acres under the low prices of the last few years, while others have kept steadily on doing their utmost to obtain a full crop of Hops of superior quality. A Sussex farmer and skilful brewer who has done so says he still believes in Hops when well grown and finished for market a fine bright sample. Such Hops must be had to brew and hop-down pale ales, especially for the export trade. His crop this year averaged 7 cwt. per acre, and he got £8 per cwt. or £64 per acre; assuredly he has reason still to believe in Hops. He is a remarkable example of what is possible in farming when the farmer is a living embodiment of industry, combined with sound practical knowledge, good sense and energy. His holding is only 100 acres in extent, but in that limited area are to be found remarkable examples of successful practice in the dairy, and with poultry, Hops, fruit, corn, roots, and green crops a fair proportion of each is seen thoroughly well done, and the excellence of the produce commands a speedy sale and profitable remuneration.

WORK ON THE HOME FARM.

So dry and hard is some of the land required for Wheat-sowing that ploughing cannot be done till we get some rain, at any rate not by horses, and those heavy land farmers who have the advantage of steam tackle are indeed fortunate. As yet we have only been able to sow some 20 acres of Wheat, and with that the seed germination is going on satisfactorily. Of course the dry weather has been a real blessing, and it must not be forgotten that there are no such things in this world as unmixed blessings. We are getting the Mangolds together in excellent order, and the work of carting to the clamps is so light upon the dry hard surface, that never was the work done better. We have already seen several flocks folded upon Swedes, and the sight has set us thinking about food prospects for next spring. Of course a heavy Mangold crop will then be available, but it is as well to have a good breadth of Swedes for the ewes and lambs to be folded on, to be followed by Barley, and to use Mangolds later on upon Rye and pastures. The first sown Tares are now well up, a full strong plant, and the Rye is also just visible. With us, our readers well know, both these crops hold a high position for spring feeding, and we shall have one more sowing of Winter Tares now for use in early summer. A field of seed Tares is also very profitable, and those who have a well ripened sample for sale now find it answer well. We know many farmers who object to seed Tares as being an exhaustive crop, but that is a matter easily set right. It is an excellent rule to apply manure to the land for every crop. No doubt this plan appears extravagant, but in reality it is not so, for with the land once brought into a thoroughly fertile condition very moderate applications of manure with each crop are sufficient.

Nothing can be more suicidal on the part of a farmer than to impoverish the land. Said the late tenant of a small farm of 90 acres, which has fallen upon our hands this Michaelmas, "If only I could have got £10 a year out of the farm I would not have left it." Now, we are bound to make it answer, and we shall do so next season, for we can say to his credit the land is fairly clean, but it is very poor, and this can be set right by a liberal use of chemical manure, and we have already got 300 sheep upon the fields.

REMARKS.

21st.—Fine and bright throughout.
 22nd.—Fair morning, bright day.
 23rd.—Slight fog early, fine day.
 24th.—Fog, gradually decreasing, in morning, fine afternoon.
 25th.—Warm with occasional sunshine, but generally cloudy.
 26th.—Dull and drizzly early, cloudy day.
 27th.—Overcast early, fine warm day.

Another rainless week, but with sudden return of mild weather, the maximum on Saturday reaching 68.8°. The weekly averages being nearly equally based on the cold and on the warm portion have come out near the average. G. J. SYMONS.

THE CAMPAIGN.

THE annual friendly contests amongst the growers and admirers of the Chrysanthemum have commenced in earnest, and despite the forebodings, which the unfavourable season to a great extent justified, the results so far have been very satisfactory. The blooms have been shown in large numbers, and the quality generally, especially in the Japanese, exceeded expectations, the incurved, though late, creditably displaying their refined characteristics. The chief difficulty growers have experienced recently has been in preserving the earlier blooms, as a most discouraging tendency to damping in the lower florets has been developed by the rains and fogs. Some who have tried to hasten their plants too much are likely to realise the fact that a mistake has been committed, but it is quite excusable, especially with beginners, as only a week or two since it seemed impossible that certain exhibitors would be enabled to enter the lists at the early shows, though they have since done so with considerable satisfaction to themselves.

It is astonishing how rapidly the societies and exhibitions devoted mainly to Chrysanthemums increase in numbers, and if any doubt were felt respecting the popularity of the "Autumn Queen," it would be effectually dispelled by an inspection of a list of shows for the present month. The season really began with the last day of October, when a successful show was held at Havant. This was followed by one at Southampton on the 1st inst., where the competition was exceedingly keen. The busy time was commenced this week, reaching the culminating point next week, and gradually declining to the end of the month. Thus a total of over ninety shows have been announced, and taking the three principal weeks; the numbers are—November 5th to 9th, fourteen shows; November 12th to 17th, fifty-four shows; and November 19th to 24th, twenty shows, the last of which we have any information being Eccles on November 30th and December 1st. With regard to the days of the week upon which the shows are held there is a marked preference for Tuesday and Wednesday, twenty-six being fixed on the former and twenty-seven on the latter; the others being Monday 3rd, Thursday 21st, Friday 11th, and Saturday 4th, the first and the last being evidently in very little favour. On Monday, November 13th; Wednesday, November 14th; and Thursday, November 15th, the greatest number of shows will be held—i.e., sixteen each on the Tuesday and Thursday, and fifteen on Wednesday.

Some of the leading shows have already taken place—such, for instance, as Kingston-on-Thames on Tuesday, where the fifth 25-guinea challenge vase was competed for, and won for the first time by W. Furze, Esq., Teddington (gardener Mr. Coombs), the Exhibition being as full of interest as usual, both as regards numbers of entries and quality of exhibits. Then followed the National Chrysanthemum Society's Exhibition at Westminster on Wednesday (and to-day), and where, apart from the numerous substantial prizes and medals offered, the national competition amongst Chrysanthemum and Horticultural Societies for a challenge trophy and prize of £10 excited considerable interest by its novelty. The Exhibition throughout amply maintained the credit of the Society by which it was provided. The Portsmouth Show opened on the same day (Wednesday), but continues until Friday, a silver cup, valued £25, constituting the principal prize, but the Show is always a large and good one in every respect.

The Ancient Society of York Florists will have an Exhibition in the Fine Art Building, York, on November 14th, 15th, and 16th, when two £5 silver cups will be offered for plants and blooms. The Kent County Society, though very youthful, merits notice for having made a step in the right direction, that of forming county societies. It has been reasonably advocated that in many cases an amalgamation of small local societies in one representing the county in which they are situated, would be a mutual advantage, and it is probable that this will be carried out more generally in the future. In some instances it might not be advisable or practicable, but it would be beneficial in numbers where two or three societies in a small district suffer both in funds and exhibits by their unnecessary competition.

The first provincial show of the National Chrysanthemum Society at Sheffield is being looked forward to with the deepest interest, and it is anticipated that the contest between northern and southern growers will prove one of the best of its kind yet held. The Show and the Conference where the "authorities" will discourse on various matters of importance, will undoubtedly attract large numbers of horticultural visitors, who may assure themselves of a hearty Yorkshire welcome. The most interesting class will be that for a representative collection of blooms, the first prize being a 15-guinea silver cup and £10 in cash. The conditions under which this prize is offered are very easy, and the competition ought to be keen, as the two other prizes are of substantial amounts—namely, £6 and £4. The sections, or any part of them to be represented, are incurved, Japanese, reflexed, Japanese reflexed, large Anemone, and Japanese Anemone, the first two in twelve blooms, distinct varieties, the others in twelve blooms of not less than six varieties, or more than two blooms of one variety.

The Birmingham Show is fixed for November 21st and 22nd, a liberal schedule being provided to insure what is usually obtained—a good representative Show. The Liverpool Show will be held on November 20th and 21st, and a fine characteristic display is expected. The great northern Show at Hull takes place on November 22nd and 23rd, and another silver challenge vase value 15 guineas is offered for a collection of blooms. A 10-guinea challenge cup is also contributed for a group of Chrysanthemums and a piece of challenge plate for a table decorated with Chrysanthemums, with liberal prizes in all other classes. The Shows named are only a few of the more important, but the districts represented by shows extend from Penzance to Scotland and Ireland, so that the admiration of the plant is not confined to any particular portion of the kingdom, and we frequently hear how societies and shows of a similar character are increasing on the Continent and in America, especially in the latter country.

Already a proposition of a singularly interesting character has been made with respect to next year, and it is worthy of the immediate attention of Chrysanthemum lovers. It is believed that in 1789 the large flowered Chrysanthemum was introduced to European cultivators, and it has been suggested by Mr. W. Holmes that 1889 would be a fitting opportunity for celebrating the centenary. A series of shows or a great Chrysanthemum fête might be rendered an important and highly attractive gathering next November. But to insure the attention and success such a scheme would merit it should be taken in hand at once, and the best method would be to appoint a committee to consider the matter and receive suggestions. A programme of some kind ought to be considered before the show season has concluded this year—say at Sheffield—and growers would then have ample time to prepare. If well started there would be no doubt about the support obtainable. If it were possible to grow a large collection of varieties carefully and experimentally with a view to comparison and determination of synonyms, a most valuable service would be performed. The work of comparison might well be undertaken by the Floral and Catalogue Committees of the National Chrysanthemum Society, and the only difficulty seems to be providing for

the cultivation of so large a number of plants, but we think this might be overcome, as several are favourable to the idea who could assist materially in its furtherance.

THE WEATHER AND SOILS.

THE past summer will long be remembered by gardeners as a most trying and perplexing one. In the spring grave doubts were entertained that we might have a repetition of the previous summer's hot dry weather, as perhaps there was hardly ever known a drier seed-sowing time; so dry, in fact, that the work at that busy season was greatly retarded, and the proper germination of seeds generally was a matter of serious consideration, when so much depends upon warm genial showers at that season to give all vegetable life a good start, so essential for securing successful crops. However, our anticipations were greatly upset, as the following months proved a striking contrast to the same of last year. Week after week nothing but dull sunless days, with heavy rainfalls and cold nights, the effects of which are now easily traced in our fruit crops. Soft fruit, such as Raspberries and Strawberries, were soon over, and those that were obtained were mostly deficient in merit. The cold nights were greatly against Apples and Pears swelling freely, while the sunless days prevented the fruit attaining a good colour, and in many cases a good flavour, though the fine weather of late has done much to improve matters in those respects.

The effects of the past season upon the fruit crops is not so much the subject of my remarks as the effect it has had upon the soil. Though we may have had what might be termed a wet summer, the soil in many places a few inches below the surface was, quite recently, as deficient of moisture as it was last season at this date, at least such was the case in this neighbourhood. The land received such a thorough parching last year, followed by an unusually dry winter, that the rain has been absorbed on the surface, and much is needed to penetrate thoroughly to what I may call tillage depth. This has come forcibly under my notice the last few days. We are preparing land somewhat extensively on this estate by trenching, with the object of planting later on. In each position where the soil has been broken up the second spit was so hard and dry that the pick had to be constantly employed, and to use the men's own words, "It's as hard and dry as though a fire had been under it."

Another case under notice was in removing Peach trees from outside walls to a late Peach house. It was surprising to see the state of the soil, in spite of frequent waterings and syringings during the summer. This points in a very forcible way how misleading and dangerous a summer like the past might prove to fruit trees by trusting to outward appearances only, especially to trees that are growing under what I may term unnatural conditions, such as small trees and Vines in restricted borders. It is the practice of some to cover outside Vine borders at this season to protect them from winter rains and snow; a wise course, no doubt, in some cases, but if adopted this year without a thorough examination of the border to some depth, the evil, I believe, will be shut in instead of being kept out. Over-dryness at the roots of Vines or any fruit-producing trees is as injurious at the present season as at any during the year, by producing premature ripening and fall of the foliage before it has carried out its proper functions in drawing up a sufficient quantity of sap for the proper development of the buds for future fructification. I have known Vines that have not been all that could be desired to have suffered from over-dryness of the border, while the evil has been attributed to a cold wet one, but upon a thorough examination, the moisture for a few inches on the surface has been misleading, the bottom half of the border being as dry as dust. This is greatly brought about by trusting too much to the natural rainfall, or by watering in dribbles, forgetting that Vine borders are mostly provided with artificial foundations to secure thorough drainage. This being so, the ordinary rainfall cannot possibly be sufficient to keep the roots in a proper state of moisture, as apart from the great quantity of water a Vine requires to insure perfect health, there is sometimes this over-drainage going on, besides evaporation by the sun and air acting on the border. The more elaborate and expensive the formation of the border is, the less chance is there of its being a successful one, unless time and attention can be bestowed in copious waterings.

It is most important that an accurate register of the rainfall be kept in all gardens, as this is of great assistance to the cultivator; in fact, without such a guide one really works in a haphazard way, as sometimes a shower is very misleading, often appearing more than what has really fallen, and though at times we may have 1 inch of rain—a heavy fall for twenty-four hours—still, when we come to reckon it up, it is not such an enormous quantity for a

border 3 or 4 feet deep, full of roots, and thoroughly drained; in fact, during the growing season, it is almost impossible to overwater such borders. To neglect giving them sufficient is a sure way of driving the roots out. If they cannot find their natural requirements in the border, especially moisture, they wander in search of it. The consequence is the roots suffer from cold more than from over-moisture—or the two together—the result being inferior Grapes, and the expense of forming elaborate borders is thrown away. Not only are Vines often misjudged in this way, but also fruit trees trained to walls and buildings. These sometimes receive a check during the year from insufficient moisture at the roots, thereby doing secretly an amount of evil which is irreparable the following season.

These remarks are made with the view of throwing out a hint that though we may have the past ungenial summer fresh in mind, we must not be led away with the idea that sufficient rain has fallen to supply the wants of our fruit trees, especially those growing under what I term artificial conditions, such as alluded to above, when perhaps the soil is in a perfect state of dryness, and it would be a wise course for anyone to examine their fruit borders thoroughly, to see that the past perplexing season has not been misjudged, and thus guard against serious results.—R. PARKER, *Impney.*

FORCING LILY OF THE VALLEY.

I HAVE often heard those soliciting orders for Lily of the Valley roots assert that they could readily be forced into flower by Christmas, but if this statement is not misleading in all cases it certainly is in a great many, as it is only with exceptional facilities that Lily of the Valley can be forced into flower in December, or indeed in January. Some hundreds of crowns or scores of roots may be placed in to force for flowering before the new year, and some of them may produce a few sprays by that time, but a dozen spikes from as many clumps cannot be regarded as successful, and I am of opinion that Lily of the Valley cannot be had satisfactorily, as a rule, until February and onwards. I make exception in the case of places specially constructed for forcing for market, but my remarks apply to the majority of private gardens and almost all amateurs. I have known gardeners to be told by their employers that they had seen "such lovely Lilies of the Valley from Covent Garden" the latter part of December, and some of them could not understand why it was not being produced at home at the same time. This is easily explained—first by stating that Lily of the Valley is one of the most difficult of all plants to force at mid-winter, and, secondly, it is only in very few gardens that the forcing appliances are so good as to be able to accomplish it. Buying "specially selected crowns" is often held out as an inducement to secure early flowers, and good crowns will blossom before weak ones, but the best crowns count for very little where the forcing appliances are deficient, and no one need run away with the idea that if they only buy the best of crowns flowers will be secured at any time. I never mislead anyone on this point, neither do I encourage anyone to force for Christmas flowers, but I strongly advise all to reserve their best crowns and clumps until the turn of the year. The pure white graceful and sweetly fragrant sprays will be as much valued in February or March as they would be in December or January, while three times the quantity will be produced in spring to what is possible to secure at midwinter.

I do not write without experience. I have tried many times to have "fine Lilies of the Valley for Christmas," but regarding them as favourably as I could, they never merited being termed more than "miserable." It is not so, however, with our spring roots that are forced in the same structure, as these produce beautiful green foliage and a profusion of flowers. I suspect if you were chronicling all attempts to force Lily of the Valley in December five hundred failures and one success would be the average result. It is as an Easter flower rather than a Christmas one that Lily of the Valley should be grown. As a rule foreign crowns are better developed and matured than home-grown ones, and many of the former give profitable returns in February and March, while good home-grown roots will always force well by Easter.—M. M.

NOTES ON GRAPES.

THE exceptional season we have just passed through has left its mark upon many kinds of garden produce, especially upon both out and indoor fruits, which have in many cases been unusually late in coming to maturity, and in others deficient in either colour or flavour, and in some instances lacking both these essential qualities. Doubtless many useful lessons may be learned by noting the effect the dull wet summer of 1888 has produced upon different varieties

of Grapes. As far as my observations have gone when attending shows in various parts of the country a great want of colour has been noticeable in white Grapes, especially at some of the early shows. I naturally expected to find them rather green after so prolonged an absence of sunshine, but in this respect the samples exhibited were, as a rule, far worse than I anticipated. Towards the end of the summer a great improvement could be seen, but in no instance did we see Muscats possessing that beautiful bright tint which they should have assumed during more sunny seasons. Black Grapes have not, on the whole, been so well coloured as usual, although the falling off in that respect has not been so marked as in the case of white Grapes. Occasionally samples of splendid colour and finish have been met with, but these have been the exceptions rather than the rule. The old and general favourite, Black Hamburgh, seems to have been the most satisfactory in point of colour, of all really first-class black Grapes this season, which goes to confirm the opinion I have long held, that this variety colours quite as well in dull as in bright weather, and if the weather happen to be very bright at colouring time should always be slightly shaded, excepting those cases where the Vines are growing in old and comparatively dark houses.

Alnwick Seedling has fully maintained its reputation of colouring perfectly under all sorts of conditions. Either in a warm house or a cool one it seems to colour equally well, and whether the weather is bright or dull there is no perceptible difference in that respect. By far the best bunches I have seen of this showy Grape were growing in the large vinery under the charge of Mr. W. Taylor at Bath when I visited his now famous Vines in August last. The bunches were unusually large and shapely, the berries blue-black in colour, and carrying a dense bloom. Gros Maroc has also in many cases coloured well this season, but it is by no means so reliable in regard to colour as the last named variety. It is often seen in the hands of Grape growers of the front rank very deficient in that respect. This I think plainly shows that the art of colouring Grapes is by no means easily mastered; each locality and the varying conditions of each season must guide our treatment. When once these facts are thoroughly understood I believe it is possible to colour many varieties of Grapes as certainly in one season as another, but not so with all.

I am firmly convinced that to have that noble yet capricious Grape, Madresfield Court, in a perfect condition we are to a great extent dependent on the state of the weather during the time the colouring process is going on. In very few instances during the past season have we seen this Grape in really good condition as regards colour, and at the September show held at the Crystal Palace, where we should expect to find it well finished if anywhere, the class provided for Madresfield Court was notoriously the worst in the show, although several of the exhibitors in that class have in previous years shown the same variety in exceptionally good condition. This to my mind clearly shows that either a certain amount of sunshine, or at least immunity from a series of wet days during the colouring period, is necessary to ensure good colour without cracking, or we have yet to learn how we can supply by artificial means the conditions under which these evidences of high culture can be ensured in unfavourable seasons. When the weather is dull without being wet the matter is simple enough. Maintain a steady heat in the hot-water pipes, and keep a little air on the top and bottom ventilators constantly; but when a succession of wet days is experienced the case is quite different. During such weather a little air may be admitted at the top of the house with perfect safety, but the moment the bottom ventilators are opened the damp air finds its way into the house and cracking takes place in a few hours. Constant watchfulness on the part of those in charge soon discovers that cracking has begun. The bottom ventilators are at once closed, more heat is kept in the hot-water pipes, and cracking is arrested, and it is this want of bottom ventilation that has to answer for lack of colour in Madresfield Court this season; at least such is my opinion. It is a matter of choosing between two evils—cracked berries on the one hand by giving bottom ventilation in damp weather, or lack of colour through not giving it. Those who are situated on high ground have a great advantage in colouring Grapes. Low-lying districts during August and September are frequently enveloped in cold fogs and mists at night (which are well known to be detrimental to the colour of Grapes) while the air on the rising ground around is perfectly clear and bracing. Large bunches of Gros Guillaume have not coloured quite so well as usual this season, excepting cases where the Vines were started very early. The pleasant sunshine which we have experienced during the past few weeks has, however, improved matters considerably.

Of all white Grapes Muscat of Alexandria has shown the effect of the season in the most marked degree. That beautiful bright amber tint which all strive to attain has been conspicuous by its absence among exhibits this season, although in a few instances

during the September shows some of the examples staged of this fine Grape were of excellent colour for the season, notably those shown by Messrs. Taylor, Pratt, and Goldsmith at the Crystal Palace Show. Foster's Seedling and Buckland Sweetwater among white Grapes seem to have been the least affected by the absence of sunshine; indeed those that won the premier position in the class for any other white at the above named show could scarcely have been improved in colour. Foster's Seedling as shown by Mr. J. Lloyd (who invariably colours this variety well) at Taunton, was very bright and clear, as also were some good bunches I saw at Gunnersbury Park. Golden Queen, when grown in an early house, has in some cases assumed a clear bright colour, but in later houses it has this season been disappointing, never getting beyond that "cloudy" appearance which generally characterises the variety when grown under the most favourable conditions, as it requires plenty of light from the time the berries set, and abundance of heat and air when ripening. Trebbiano where plenty of time has been given for ripening has improved in colour wonderfully during the last few weeks' sunshine, and is with us as well coloured as in ordinary seasons.—H. DUNKIN.

IN THE MIDLANDS.

DURING a recent run out of town I saw more of horticultural interest than I shall perhaps ever be able to record, but that is no new experience. More than once I have made a resolve to narrate all the episodes of a journey, but failed to complete the work. Too much was perhaps done at the beginning, and the end has not yet been reached. It may be well, therefore, to try a change of tactics, dwelling first on what was seen last, touching lightly on points of call and objects on the way, returning to these as opportunities may permit. It is no doubt a roundabout way to the midlands *via* Ipswich and the east coast, but as I wanted to see the tree that produced the twin Apples, round and Pear shaped, from the same stalk, a quick run was made to the busy Suffolk capital by a Great Eastern express that had no time to stop by the way. The tree was found in the back yard of a public house. It is a young tree, and had borne about thirty of the curious fruits as perfect in shape as Pears could be, yet Apples, which it produces in "proper" form also, the two kinds from the same truss of blossoms. There is no mistake about it, and, what is more, the tree had never been grafted, but was either a seedling or a sucker. Its origin, however, cannot be traced now, nor can an example of good culture in the production of Pears be dwelt on, and the way in which canker is conquered by their grower, Mr. R. Garrod, without either dressing the branches or touching or feeding the roots.

The next call was at Bury St. Edmunds, for Nowton, where Mr. Edward Luckhurst is managing an estate of 5000 acres, and making neglected and impoverished farms profitable, showing as fast as he brings the land into condition that farming will yet "pay." Then as a chance there is something to admire in Mr. Porteous Oakes' pleasure grounds and unique Conifers. There is much of interest in the old ecclesiastical town of Bury, including its abbey gardens, and to horticulturalists a famous townsman, Mr. Peter Grieve, the father, so to say, of the great race of golden tricolor Pelargoniums. Mr. Grieve lives retired a gentleman in the true sense, and widely respected. As may be imagined he begins to look ancient, but nothing in comparison with a pillar of the historical church of St. Edmunds, on which is affixed a marble tablet containing the names of the nobles who before the high altar took oath of the ratification of Magna Charta 670 years ago come the 20th of this month. I am tempted to dwell at Bury in such good company as the "raiser of Mrs. Pollock," but must rush on through the Fens to Peterborough, there changing train for Ketton for a call on Mr. H. Divers. So far as I know he has the finest Peach houses in the kingdom under his charge, and is certainly one of the best cultivators of the fruit. He gathered 6500 fruits, including Nectarines, during the season; also managed to cut 9000 Maréchal Niel Roses out of one of the houses, grand blooms from vigorous plants grown on the rational system. Ketton, however, must be left, for Mr. Richard Gilbert had to be called on at Burghley and his vegetable novelties inspected, his Universal Savoy, which is as good as it is distinct, and the Victoria Broccoli, which stirred a good clergyman into poetry, but I can only remember two lines of the verse:—

"As a cure for all ills, e'en superior to 'Cockle,' I
strongly commend Richard Gilbert's White Broccoli."

A rhyming feat worth mention; perhaps I shall think of the rest of the lines some day. From Burghley the next call is at Pinchbeck, but as something has been heard of Mr. C. Parker's success in Gooseberry and Apple growing there, we will push on to Southwell, *via* Lincoln, to see an extraordinary combination of Apples and Osiers that will be more feebly referred to, and from thence to Nottingham to the end of the journey, Beeston and Chilwell. Much cannot be said about either during the Chrysanthemum month, still perhaps space can be found for a few lines.

CHILWELL.

A note has already appeared on the Chrysanthemums in, to employ the familiar appellation, "Pearson's Nurseries," and an illustrated advertisement last week gives an idea of the display. Imposing as is the view of the large show house there represented, it may, without

hesitation, be described as far short of the reality. A grand house is grandly filled with plants, as all will admit who see the sight before the flowers fade. They will also see other large structures filled with *Chrysanthemums* in various stages for the production of flowers in abundance from now until February, and perhaps later. They will see such banks of Maidenhair Fern in one of the long houses as cannot be seen elsewhere, as much money being, perhaps, realised by the sale of fronds as from the Grapes above them. "Plants cannot be grown under Vines" is a very old story, only true, however, in so far as the wrong kinds are attempted. Ferns are the right kind, and at Chilwell they are better than if there were no shade from the roof, while the Grapes are as good as if there were no plants in the house. But the structure is lofty, and with more diffused light than if it were low, and less damp also. Be that as it may, there is the combination, and it is most satisfactory. It will be seen that Orchids are growing well and increasing in numbers, not the costly varieties, but useful kinds that produce acceptable flowers freely. Quite a young forest of one of the finest of berried plants, *Ardisia crenulata*, will be admired. enough, one would think, to stock the country, and the clusters of fruits will remain fresh for a year. It is one of the best of room and corridor plants, and will keep healthy in a lower temperature than is popularly supposed. There is no cessation in the work of *Pelargonium* raising, for the sufficient reason that the new "sets" of each season pass off as readily as ever, and the house is always gay; perhaps the lofty back wall and facing almost due north enhances, by contrast, the effect of the colours, for it is clothed with the dark green elegant leafage of *Asparagus plumosus nanus*, which there luxuriates, showing that it neither wants sun nor a high temperature for thrifty growth. The worst, or the best, of it is they are always cutting the leaves as the demand is so great for them for associating with flowers, being found to last much longer than Fern in dry and heated rooms. Avenues of *Maréchal Niel* Roses in pots, also Vines, show how well their culture is understood and how great the demand for them must be.

Some of the finest houses in the trade, usefully occupied, are the characteristics of Chilwell, but it was not these alone, or mainly, I went to see. My chief object was to have a glance at the Improved, or as it is also known as the New Northern Greening Apple growing. Apples on plates in shows are all very well, but I have arrived at the conclusion that knowledge of the character of the trees is essential for determining the true merits of varieties. The best show fruits are not always the best to grow for profit. Some are both handsome and useful no doubt, but others are a good deal more tempting in appearance than they are serviceable and reliable. The Improved Northern Greening is not a "show" Apple, that is, the fruits are not of enormous size and glowing in colour, but they are of good saleable size, uniform, faultless in shape, and rank amongst the heaviest according to size of any, and are long keepers. A dish was certificated last month at Chiswick, and having seen the trees and noted their sturdy growth and free spurring character I am satisfied this is an Apple of real usefulness, hardy, free and good. It has been long grown in the midlands and north, and sorts that succeed well there have not much the matter with them. I do not know whether Messrs. Pearson grow more of this than any other, but it is evidently a favourite. They grow both trees and fruit, having orchards in bearing as well as nurseries for raising trees. I had only time to visit two of the latter, and one, the largest, a little surprised me, for it is fifteen acres in extent, and the late Mr. J. R. Pearson built a wall right round it. It is a single brick wall 4 or 5 feet high, stability being imparted by its form thus—

I did not inquire, but it was built possibly for keeping out rabbits as well as for the training of dwarf trees, and it certainly answers both purposes. Clean culture was manifest, and the routine work well done. And now I must leave Chilwell, calling at Beeston, and having a glance round the establishment of

MESRS. FOSTER & PEARSON.

Though only twenty minutes could be spared for the glance, the time was sufficient for appreciating the extent and completeness of the manufactory, but not for noting the requisite details for a full descriptive account. Nothing of that kind will be attempted. Mr. Foster has retired from the business, and resides in a pleasant residence on the borders of the town. Long ranges of glass structures can be seen "over the wall," suggesting that the owner of them indulges in the pleasures of horticulture. Mr. Henry J. Pearson, who is well known for his business activity, quickly pointed out the main features of the works, setting into motion with the turn of a handle different machines for planing, chamfering, morticing, turning, boring, &c., showing with what celerity and accuracy the work in wood and metal is completed.

Almost everything seems to be done by machinery, except painting and glazing, these operations being still, I think, done by hand. Some of the machinery is very ponderous, and one contrivance for making valves is said to be a combination of seven patents. The number of throttle valves made suggests their use in other than horticultural structures, and in other lands than our own. Everything connected with garden structures and their heating appears to be made on the premises, and the extent of the work is indicated by the provision made for its prosecution. The joiners' shop is 140 x 30 feet, and men and machinery all in action. The smiths' shop is upwards of 60 x 40 feet, full of boilers and men and noise. Next are two foundries, a good deal larger, in one moulds being shaped in sand for the reception of the molten metal

from the cupola, for making fittings of various kinds useful and ornamental. Cutting out flower beds in lawns is rough work in comparison with the intricacy and accuracy of the receptacles cut in the sand from patterns, and out of which the articles come sharp and clear in outline. Then there is yet another huge building in which hot-water pipes are made, and every one tested at fifty times the pressure it is ever likely to endure.

Several other parts—offices, stores, fitting rooms—were passed through, including one in which large frames and roofs are put together before being sent away for erection. As may be expected, the timber stacks are enormous, and sheds for drying extensive, the supply being maintained several years in advance of requirements for ensuring high seasoning; indeed everything appears to be well done, and the establishment is well worth seeing by persons who are interested in the manufactories of horticulture.—A WANDERER.

HIGHLY PRICED CYPRIPEDIUMS.

THE best and scarcest of the hybrid *Cypripediums* still command large prices, and it is evident that, apart from the beauty of the plants, purchasers consider money so expended as safely invested. At a recent sale in Cheapside, Messrs. Protheroe & Morris had a plant of *Cypripedium Marshallianum* which was sold to a gentleman residing in America for 150 guineas. This *Cypripedium* is supposed to be a hybrid, but we do not think the parentage has been satisfactorily determined. On the same occasion a small plant of *C. leucorrhodum* was sold for forty guineas.

ORCHIDS IN NOVEMBER.

THERE is quite a wealth of Orchids available during the last three months in the year, among these being many very valuable and beautiful species and varieties. Unfavourable weather in the metropolitan area unfortunately materially shortens the duration of the bloom on thousands of plants, and in this respect the provincial growers have a decided advantage. Nowhere else is this more apparent than at Cheltenham, and all who pay a visit at this time of year to Mr. J. Cypher's nursery in the Queen's Road cannot fail to be impressed by the vigour, floriferousness, freshness, and general excellence of the Orchids there grown. To me it is a real treat, and which I never miss if it can well be avoided. The lovely white flowering and very sweetly scented *Angraecum leonis* is most attractive, and *Angraecum sesquipedale* will shortly be at its best, many strong spikes being formed. *Aerides Lawrencei* is represented by several grand plants with extra fine spikes, some with as many as thirty-four blooms on them. The original plant of this exceptionally fine variety when first imported fetched 235 guineas. It was bought by Sir J. Trevor Lawrence and named in compliment to Lady Lawrence. Mr. Cypher has good reasons for asserting they have some of the finest plants of this *Aerides* in the trade. Neither *Angraecums* nor *Aerides* succeed well in a strong heat and dry temperature, an intermediate temperature and an atmosphere that suits the majority of exotic Ferns best suiting them. The same remarks apply to the *Vandas*, of which Mr. Cypher has good plants of *cærulea* and *insignis*, flowering freely.

The best of the *Cattleyas* now in flower are *C. maxima* and *C. Bowringianum*. The latter may be described as a winter flowering *C. Skinneri*, and both are always serviceable at this time of year. *Cypripediums* are largely grown by Mr. Cypher, and there are always some good species and varieties in flower. At the present time the most attractive are *C. insigne*, *C. insigne Maulei*, *C. insigne punctatum violaceum*, the last named being very fine; *C. Spicerianum* very strong and the forms good; *C. Harrisonianum*, *C. Roezli*, one of the freest to flower; *C. Haynaldianum*, and a fine form of *C. Sedeni*. In the same house there are several well flowered pans of *Cœlogyne ocellata*, and *C. cristata* in variety promises to be as fine as usual, many of the specimens being extra large.

Dendrobiums will soon make quite an imposing display. *D. Jamesianum* is very showy and *D. formosum giganteum* still more so. There are numerous strong plants of the latter in 4-inch pans, each carrying on an average nine fine flowers. These and *D. bigibbum*, of which there is quite a large stock of extra strong and very floriferous plants in small pans, are grown suspended near the glass in strong heat, this treatment suiting them admirably. The lovely hybrid *D. rhodostoma*, raised by Mr. Seden, and obtained by crossing *D. Huttoni* with *D. sanguinolentum*, appears to be perpetual blooming, and is a grand acquisition. *Lælia Perrini superba* is very

beautiful; it is bearing three large blooms on a spike, the labellum being well formed and of a brilliant crimson colour. The ordinary species is also very showy, and good for late autumn flowering. *Odontoglossums* are very numerous and the majority extra strong. A considerable number will soon be ready for the show house, among these being *O. Roezli* and *Roezli alba*; *O. grande*, of which there are several splendid varieties; *O. Rossi*, just coming into bloom, and the lovely *O. aspersum*. This is said to be a natural hybrid between *O. maculatum* and *Rossi*, and Mr. Cypher's has one extra good spike showing.

Oncidiums are largely grown for autumn and winter flowering. The most noteworthy among these is the lovely *O. Jonesianum*, of which there are many grand plants in bloom, the strongest spikes bearing as many as twelve good blooms. *O. Forbesi*, also a fine variety, has one fine spike with fourteen blooms. *O. varicosum* or *Rogersi* is most free flowering, and there will soon be a grand show of this showy species. *O. crispum* and *O. tigrinum* are likewise worthy of mention, and I cannot close these brief notes without reference to the well flowered pans of the charming Indian *Crocuses*, *Pleiones birmanica* and *lagenarica*.

NARROW VINE BORDERS.

THOSE making new Vine borders I recommend to use good yellow turf fresh cut from an old pasture. Do not chop it up as is generally recommended, but cut it in pieces of about 8 inches square. After the width and depth of the border has been decided, which I think should be 14 or 16 feet wide and 2 or 2½ feet deep, certainly not more, give about 6 inches of good drainage, which should consist of broken brick, flower pots, or clinkers from the boiler fires. If the bottom and sides can be concreted and cemented so much the better, as this will prevent the roots penetrating into soil which might not be suitable for the production of fine Grapes, and which is in some cases the cause of shanking. Having prepared the border for the soil, cover the drainage with turfs, grass side down, and put a good sprinkling of old lime rubbish and crushed bones or Thomson's Vine manure over this. Then proceed to place on this another layer of turfs, cut into pieces about 8 inches square (if in the case of lifting old Vines all across the border). But where young Vines are to be planted, I recommend only 3 feet width to be made the first year, the rest of the border to be made up in 3 feet widths every year till completed. As before stated, in renewing old Vine borders it is necessary to make them the full width at first. After having the first layer of 8 inch square turfs laid, put another good sprinkling of old lime rubbish and crushed bones, and proceed in this way until the border is within 4 or 6 inches of being completed, then well spread out the roots of the Vines, and cover with chopped turf, lime rubbish and crushed bones, Thomson's manure, or both.

In wet cold districts I recommend that the border be all inside. In fact I have not much faith in outside borders anywhere. The width I have stated is ample to grow any Vines in, and Vines planted in borders made up in this manner will last in good bearing condition for fourteen years or more, provided they are properly managed and not over-cropped.—G. HILTON.

As stated by "Spectator" and "W. S.," Vine borders, as a rule, are too large. It is very well where the natural soil and drainage are good to let the Vines have an unlimited root run, as then they pick up food as they travel. Many of the large old Vines owe their success and vigour to this cause, and probably if the borders had been restricted they would not succeed so well. I am a firm believer in small, well drained, and sound borders, as then you can "feed" up and know that the roots receive the benefit of whatever is applied in the form of liquid feeding or rich top-dressing. We have four restricted borders, and the Vines are doing well. Madresfield Court does capitally in a restricted border, bunches and berries of fine colour, and not one cracked berry. We treated the Vines in this house, when the Grapes commenced colouring, the same as I recommended for Lady Downe's to prevent scalding. I feel convinced it is the atmospheric conditions which cause this Grape to crack. A firm border is also necessary for the successful growth of the Vine, but the state of firmness must depend upon the class of soil you have to deal with. With some soils, even if one half is pounded brick and mortar rubbish, if trodden on it will run together like concrete. For instance, the soil we have to deal with is a very stiff limestone clay. When wet it will stick like birdlime, and if trodden on whilst wet the impression caused by the foot will hold water like a cup.

In that excellent little treatise, "Vines at Longleat," Mr. Taylor states that the more trampling the border has the better, if not trodden on immediately after watering or until the surface is dry; and in the graphic description of the gardens at Cardiff Castle twelve months since by "A Tourist" we read of two 16 stoners trying to make an impression on the borders there and failed, and at the same time praising the wonderful crop of Grapes. When one of the two was here a short time afterwards and was admiring the state of the Vines generally in a large Hamburg house he said "there is nothing like a firm border." I thought we will have a firm border if it will lead to further improvement. When top-dressing time arrived so much loam, burnt refuse, and pounded lime rubbish was put on and well firmed down with the back of a fork and excepting after watering we did not trouble about tread-

ing on the border in the least, and at the same time was congratulating ourselves on having a firm border. In the autumn we had lifted the roots in the outside border, and for a time everything looked promising, but when colouring time arrived the Grapes did not seem to improve as they ought considering the firm border and the quantity of healthy roots below the top-dressing when it was applied; so I anxiously looked for the roots working into the top-dressing, and looked in vain, for they were quite dormant. We had practically "sealed up the roots from the air." After seeing how matters stood it did not take long to decide what to do. Off came the "top-dressing," and a lighter dressing was given in its place, with a mulching of littery manure. The roots soon commenced to work upwards and the Grapes and Vines improved rapidly. A little warning may be of use, for after reading the remarks of "W. P." some might be trying their hand at the ice mallets irrespective of the soil they have to deal with. It is one of those fallacies of the culture as expounded by Mr. Goodaere—"What will succeed in one place will not in another."—A. YOUNG.

JASMINUM HIRSUTUM.

JASMINES are all favourites with plant-growers, as the majority of the species are not only extremely ornamental as climbers, either in

FIG. 48.—JASMINUM HIRSUTUM.

warm or cool houses and in the outdoor garden, but they also yield such an abundant supply of fragrant flowers that their utility is unquestionable in most establishments. The one of which a spray is represented in the woodcut (fig. 48) is chiefly remarkable for its dwarf shrubby habit, which admirably suits it for culture in pots in a stove or intermediate house, where with moderate careful attention to the culture it will produce its flowers as freely as could be desired. In Bengal, where the plant abounds, Dr. Roxburgh has stated that the heads sometimes contain thirty flowers each, but in this country they do not attain more than a third of that size, usually bearing from six to ten flowers in each cluster. Even, however, in this condition they are very attractive, as not only do the shoots produce flowers at their extremities but also from the side shoots, so that the growths are often clothed with flowers for a foot or more from the apex. The leaves are elliptical, dark green, and with the petioles and stems are thickly studded with hairs, whence the specific named is derived; and the flowers are large, pure white, and fragrant, on stout peduncles, and thickly clustered.

It is considered that the first plants were sent from the East Indies to Lady Amelia Hume by Roxburgh early in the present century, though at one time it was thought to have been grown by Miller in the middle of the eighteenth century, as he mentions Linnaeus's *Nyctanthes hirsuta*. But this has been proved to have been founded upon a specimen of *Nyctanthes arbor-tristis*.

J. hirsutum is easily grown, and it only requires a compost of light

turfy loam, sand, and leaf soil, the temperature of a stove, and liberal supplies of water during the summer.

FRUIT TREES ON NORTH WALLS.

THE profitable cropping of north walls is a subject which interests many readers. Every square yard of them may be made profitable, and they will produce crops that will succeed others grown in more favourable positions. Our favourite trees for planting on north walls are Morello Cherries, Red and White Currants, with Gooseberries. We have tried Apples and Plums on them, but could never make them profitable. They bear sometimes, but do not always ripen, whereas the Cherries, Currants, and Gooseberries never fail. From trees in a sunny position we gathered Morello Cherries during the first week in August last, and from trees on a north wall we gathered the Cherries on October 5th. Our Cherry season, therefore, extended over nine weeks, but it would have fallen far short of this had it not been for the north wall trees. Gooseberries remain good on a north wall from three to four weeks after those in the open, and Currants longer still; the fruit in both cases is always plentiful and good.

Before, however, beginning fruit culture on north walls it should be seen that the soil is in proper order, and the soil in this position is not always suitable. It often happens that those who have to deal originally with north walls consider that they will never be of any value, and their neighbourhood is used as a receptacle for all kinds of bad soil and refuse. To plant in this would be to court failure, but if all unsuitable soil is removed, drainage introduced where necessary, and as much attention given to the soil for trees on a north wall as is generally devoted to south borders, success will be permanent. Without this care it would be better to leave north walls alone, as it will only be throwing away plants and what little labour is given to them to attempt their culture under such conditions. From November to March is the season when north walls may be planted, and only healthy young trees or bushes should be introduced.—A KITCHEN GARDENER.

THE ROSE SEASON OF 1888.

FOR many years I have been enabled to chronicle in the pages of the Journal my impressions of the Rose season. Year after year for some years now we have been looking for that which ever seems to elude our grasp—a good Rose season. Our hopes run high, our expectations are great, and then when we are looking at last for the fulfilment of our hopes the unexpected happens, and disappointment comes. Never has this been more thoroughly the case than with the past season. Conditions seemed to be promising, we had had a splendid summer in 1887, everywhere people spoke of well-ripened wood, so that even if severe frost came the plants would be able to resist it. Now it is very difficult to write about weather, for it varies so much in different parts of our islands that what I might write about Kent would not in the least apply to Surrey, although a contiguous county. We had no intense cold here, but we had two heavy falls of snow, which lay upon the ground for weeks, and kept the plants warm and comfortable. When pruning took place, which was very late, there was hardly any wood to be cut away on account of its being frost-bitten. We had no late frost, and the young shoots started away without let or hindrance, the bloom buds were formed, and then set in that long period of drought, and low temperature occurred, which ruined our hay crop and did so much harm in our gardens. We had snow as late as the 9th of April; during May and June hardly any rain until the end of the month; and throughout July, as many organisers of Rose shows know to their cost, heavy drenching rains and thunderstorms, which were, as is their wont, most erratic in the way they dispensed their favours. This was especially the case with the provincial show of the National Rose Society at Darlington, where a thunderstorm broke over the town just as the show was opened, and neither before nor after was there any more rain that day. The consequence of all this was that it was the most aggravatingly disappointing season that I ever recollect. And this did not end with the exhibition season, for I have rarely known a worse autumnal season. We had on October 3rd all over the country a frost which varied in its intensity in different places, but everywhere was quite sufficient to cripple the autumnal bloom. It was succeeded by a time of thick fogs and heavy mists, so that Roses got glued together; and although light and pleasant weather succeeded and St. Luke's little summer came in due course, yet the mischief had been done, and even the ever-faithful Teas succumbed to it. The Rose which has shone out conspicuously amidst the wreck has been Marie Van Houtte, with its fine foliage and

sweet flowers; I allude of course to the open. From the walls I have been enabled to gather some good blooms, but even these are not so many as in other years.

I have had as in other years a good opportunity of seeing the flowers which have been put up for exhibition, have attended many of the principal shows and seen many private gardens, and the verdict which I have to pronounce on the season is that it was a very mediocre one. There was an absence of really grand blooms, no Roses that cling to one's memory as superexcellent, no boxes of which one could say That is one of the best boxes I ever saw exhibited, nor was there any Rose which seemed to be good everywhere as in some seasons. And if it was bad for all Roses it was especially so for Teas and the lighter coloured Hybrid Perpetuals. Many Teas were exhibited with all their outer petals skinned off, and most light Roses of any fulness were absent from the stands. Thus of Her Majesty, out of thirteen entries at the National only one was staged, while one hardly saw any of the Victor Verdier race. Roses with fewer petals, such as Baronne de Rothschild, Mabel Morrison, and Merveille de Lyon (which seems after all to be only a sport of the Baronne) did not suffer so much; shading was in many cases of little use. So heavy were the storms that even where the beds were mulched I have known the blooms to be spoiled 2 feet up by the splashing of the rain.

All this was very disheartening to exhibitors, and then when, as was too often the case, the show day was wet and boisterous their troubles were increased. I have before my mind the case of an unfortunate exhibitor who, anxious to be in time, had come early to the show ground. His boxes were placed under a tree where he was told the tent was to be erected. After sitting there under an umbrella, the picture of patience on a monument, he was told that there would be no tent erected there after all, the Roses must go into one already erected, as the entries were so few. And so again, when we were expecting a good fight at Darlington, one exhibitor from whom we expected great things, had to telegraph that a thunderstorm, which had not extended a quarter of a mile on either side of him, had broken over his rosery and completely put him *hors de combat*. These same causes prevented the new candidates for favour from being seen to much advantage. We had hoped for much, not from foreign raisers, for I think we have long ceased to place our hopes upon their fair promises and high-sounding phrases, but there were many of home production that we were anxious to see more of—Earl of Dufferin, Sir Rowland Hill, Miss Ethel Brownlow, Her Majesty, Grand Mogul, Princess Beatrice, Mrs. John Laing, &c.; but we have been disappointed. Comparatively few of them have been shown, but as far as they have we may, I think, say that Earl of Dufferin is a very distinct and fine flower, brilliant in colour, and likely to prove a most useful exhibition Rose. Sir Rowland Hill is a very distinct Rose of an unusual shade of colour, and is, I think, sure to be a favourite. Miss Ethel Brownlow is a very sweet coloured Tea, not quite like any other flower that I know. Her Majesty still holds a very doubtful position both as to her beauty and her constitution, some maintaining that it is a vigorous and others a bad grower; but as I once heard of a gentleman saying to a fellow passenger that so and so was very much misunderstood, but that's just what a person in his position ought not to be, so I say of a Rose nowadays, that it ought to have a constitution about which there is no doubt. Grand Mogul it is impossible to distinguish in flower and habit from Jean Soupert, while it is equally with that variety subject to mildew. Princess Beatrice is a very lovely Tea, and Mrs. John Laing is without doubt a fine Rose, perhaps the best the raiser has sent out.

So far with regard to the Roses, and now with regard to the exhibitors. It must have been a great pleasure to all Rose growers (except perhaps to those who felt the power of his arm) to see Mr. R. N. G. Baker of Exeter, the champion of former days, once more exhibiting and resumed his place as the premier amateur grower. Again after the lapse of some years he has carried off the trophy, and has shown that, notwithstanding all the disparaging things said of it, the Manetti will, in some places at any rate, lead those who trust in it to victory. Other exhibitors are coming on, others taking higher positions, and, while some are retiring from the field, we are glad to think that there are others to take their place.

Although the season has been unfavourable for Teas, yet there is a manifest increase in their popularity, and on all sides I hear of beds of Hybrid Perpetuals being done away with and Teas planted in their place, while I have again to notice the increased favour with which the seedling Briar and Briar cutting are held; but we may perhaps run into error in imagining that the Manetti will never in any place find favour.

There is also, I think, evident an increasing desire to cultivate the species of Roses, and it is one that ought to be encouraged. There are many beautiful things amongst them; and now, as I am writing, the beautiful hedges of *Rosa rugosa* and the brilliant foliage of the little Scotch Rose tell us that they are deserving of consideration for other reasons than the flowers, while some additions to the charming dwarf Polyantha Roses in Little Dot and others; but, on the whole, the season has been as disappointing with regard to new Roses as it has in the older kinds.

There has, however, been no such record amongst exhibitors as in past seasons. No one has presented such a record as Messrs. Harkness did last year, or Mr. Pemberton the year before. No one has been able to carry on the fight from beginning to end and to come out victorious in the encounter, through no fault of theirs, but through the extraordinary character of the season through which we have passed.

The position of Rose societies is, like everything else, liable to change.

Some come and some go. The National's change to the Crystal Palace has been much appreciated, and the long spell of dreariness connected with South Kensington is happily at an end. A vigorous and successful effort was made to establish a Rose show at Gloucester, which it is hoped will be permanent. I have heard a great deal, although I did not see it, of the remarkable show at Tibshelf, a colliery village near Derby, where amongst other classes sixteen stands of 48's were shown. There are some societies which seem to be in a very uncertain position, while others are acquiring fresh vigour.

I have generally concluded my retrospect with some personal allusion, and hope I may be pardoned for doing the same now. I have not gone so far afield as last year, and I fear unless the National cross the border again my Scotch journeys are a thing of the past, and despite the unfavourable weather, my journeyings have afforded me much real pleasure. I have already stated how at Gloucester I renewed an acquaintance after a lapse of nearly fifty years, and in truth it is pleasant to meet again those with whom we have enjoyed pleasant meetings before, and to make fresh acquaintances. Again have I to express my sincere thanks to all those officers of different societies with whom I have been brought into contact for the unfailing courtesy and kindness with which I have been met, and again I have to say that I have been enabled to keep all the engagements I had made, and this when as every year means two to any who have passed the allotted time, I have indeed much to be thankful for. I feel it cannot last for long, but while it does it adds not a little to the pleasure of one's life to meet on such pleasant occasions so many kind and valued friends.—D., *Deal*.

A CORRECTION.

I SHOULD like to make a correction in my last letter. On page 401, thirteenth line from the bottom, for "perish" read "push," and for "ripened" read "repressed." Five lines higher up for "over-weak" read "own weak." I did not think I had sufficient genius to write badly, but am now beginning to have hopes.—W. R. RAILLEM.

IMPRESSIONS OF LONGLEAT.

A LONG-*FELT* wish to visit these far-famed gardens was recently gratified, when I had the pleasure of seeing the noble vineries and giant Vines from which the splendid Grapes had been cut that justly deserved the high honours and unstinted praise that have been bestowed upon them from time to time when placed upon the exhibition boards. Both Vines and Grapes have so frequently been fully described in the Journal that it would be superfluous for me to dwell upon them; but as there are other features at Longleat worthy of more than a passing notice, I am jotting down a few mental notes that are still fresh in my memory. The flower garden is a very fine one in every respect, and seems materially to enhance the beauty of the magnificent edifice around which it is situated. The features of the garden in question are not confined to one style of flower gardening in particular, as both ancient and modern ideas of the art are thoroughly well carried out. In a somewhat secluded enclosure adjoining the main portion of the flower gardens some relics of the ancient idea of the art are still retained in form of beds of fantastic shape outlined with broad lines of Box and Yew, which must require a great amount of both skill and patience to keep clipped into their precise and formal outline. In striking contrast to these beds is a well arranged herbaceous border, where Dahlias, both Show, Fancy, and Cactus, have flowered in rich profusion. Achillea ptarmica fl.-pl., Gladiolus, Asters, Delphiniums, and herbaceous Phloxes were looking bright and effective, and supplying plenty of flowers for cutting. Some small beds of Tuberous Begonias next attracted attention, many of the flowers being of enormous size and of fine rounded outline. A few carpet beds are well designed, and planted with the usual assortment of Alternantheras, Sedums, &c., looked fairly well; but the past season has been sadly against this kind of bedding, absence of sunshine having prevented their assuming that brilliancy of colour which is essential to make them effective. In other beds large masses of Henry Jacoby, Indian Yellow, Bijou, and Vesuvius Pelargoniums, Verbenas of various colours, edged with variegated-leaved Geraniums, were extremely imposing, while some oblong beds arranged with several varieties of bronze and tricolor Pelargoniums in zigzag fashion were very striking, the flower garden throughout presenting that neat trim appearance without which the beauty of the finest beds and borders would be greatly marred. Near the glass structures I noticed a fine bed of Carnations of a very pleasing pink colour, a variety much grown in the locality, but as yet does not seem to have been honoured with a name, which, however, I hope it will speedily receive, and be widely circulated.

Some fine Poinsettias were growing in a three-quarter span-roofed house, where they had been throughout the summer. The plants, which had made strong sturdy growth, were the picture of health, and cannot fail to make a grand display when their brilliant scarlet bracts are fully expanded. Another large house was principally occupied by Crotons and Dracenas, varying in height from a few inches to 4 or 5 feet, so as to supply plants of all sizes for decorative purposes, for which they are in great demand at Longleat. Many of the best varieties in cultivation are grown, and among others I noticed well-coloured examples of Crotons Disraeli, Evansianus, Hawkeri, Johannis, Morti, Queen Victoria, angustifolius and variegatus. In the Melon houses were some fine fruits of Longleat Perfection and Hybrid Cashmere.

Mushrooms are also very successfully grown, a long shed having been converted into a most useful Mushroom house. At the time of

my visit a plentiful supply of "buttons" were pushing through the soil. Other beds had just been spawned, while another was being constructed. Mr. Pratt surfaces the beds with good loam without any other addition, and finds it answers the purpose admirably. Standing on a bed of coal ashes in the open air was a healthy and vigorous collection of Chrysanthemums grown as bush plants for supplying plenty of flowers for cutting during the dull November months. These jottings have already grown beyond their intended length, but before concluding, I must mention that the kitchen garden was well stocked with abundance of such vegetables as are required to keep up a constant supply for a large establishment.

Everything at Longleat is carried out on a large scale. A gigantic park, a noble mansion, an imposing flower garden, big vineries and splendid Grapes, were some of the impressions made upon my mind during a somewhat hasty visit. Such gardens require a skilful and energetic chief to control and direct the forces at his command. This, the gardens at Longleat undoubtedly possess in the person of Mr. W. Pratt, who so ably presides over them.—H. DUNKIN.

EVENTS OF THE WEEK.—The Chrysanthemum Shows for the present week are very numerous, the following being the chief:—November 8th, Walton, Teddington, and Dawlish; November 9th, Crystal Palace, Leicester, and Hitchin; November 12th, St. Neots; November 13th, Moulsey, Southend, Devizes, Putney, Brighton, Northampton, Twickenham, Winchester, Watford, Cardiff, Ascot, Barton-on-Humber, Maidstone, Twyford; November 14th, Bournemouth, Chelmsford, Southgate, Ealing, Kent County, Hampstead, Faversham, Highgate, Dartford, York, and Bedford, most of these being two-day shows. On Tuesday, November 13th, the Royal Horticultural Society's Fruit and Floral Committees will meet in the Drill Hall, James Street, Westminster.

— A SPECIAL general meeting of the ROYAL HORTICULTURAL SOCIETY will be held in the Council Room, 111, Victoria Street, S.W., at 2 P.M., on Tuesday, November 13th, to take into further consideration the new code of bye-laws, and to adopt the same.

— LEDBURY FRUIT SHOW.—The following addendum to the report of the above Show arrived too late for insertion last week:—"The special prize of £1, given by Mr. Piper, was won by Warner's King, as the largest Apple in the Exhibition. Messrs. G. Paul & Son, Chess-hunt, J. Veitch & Sons, Fulham, exhibited fifty and sixty varieties of Apples and Pears, not for competition."

— JUST as we are going to press we hear that the PORTSMOUTH CHRYSANTHEMUM SHOW is a great and good one. The 25-guinea cup is won by Messrs. W. & G. Drover, Messrs. Flight, Penfold, and Inglefield following. Mr. Molyneux is first for twenty-four cut blooms, Messrs. Trinder, Flight, and Penfold securing the remaining prizes. The £10 Jubilee prize for eight specimen plants is won by Mr. W. Joy.

— CATERHAM GARDENERS' SOCIETY, SURREY.—At the following ordinary meetings for mutual improvement papers will be read on the subjects named. November 16th, "Claims and Requirements of the Kitchen Garden," by Mr. R. Catt; November 30th, "Odontoglossums," by Mr. Lemaire; December 7th, "Bouvardia," by Mr. Kimpton; December 21st, "Gesnerias," by Mr. Pearman. 1889.—January 11th, "Eucharis," by Mr. Hicks; January 25th, "Fern Spore," by Mr. G. H. Rose; February 8th, "The Benefits of a Cottage Garden," by Mr. F. A. White; February 22nd, "Melons," by Mr. Wood; March 8th, "Libonia floribunda," by Mr. Wyatt; March 22nd, "Cucumbers," by Mr. Papworth; April 12th, "Tuberous Begonias," by Mr. Brand; May 10th, "Mushrooms in Frames," by Mr. D. Jones. Meetings will be held at the Workman's Club at 8 P.M. each evening. Members' subscriptions are 6d. per quarter (payable in advance) in October, January, April, and July. New members may be admitted at any ordinary or Committee meeting upon payment of an entrance fee of 6d. The lending library consists of five standard works on horticultural subjects. These are lent to such of the members as apply for them, according to priority of application. Mr. R. Catt is the Assistant Secretary.

— HORTICULTURAL CLUB.—We are requested to publish the following, and readily comply:—"The Club has now been in existence for twelve years, and has played no unimportant part in keeping alive

the interests of horticulture, both by gathering together in social intercourse those who are interested in the pursuit, but also in the dissemination of knowledge by the papers which have been read at the meetings, and afterwards published in the gardening papers. The Committee have recently come to arrangements with the "Hotel Windsor" Company, Victoria Street, Westminster, and the Club has entered upon the occupancy of its new quarters there. The situation is central, close to the offices of the Royal Horticultural Society, and within three minutes' walk of the St. James' Park Station of the District Railway, and omnibuses to all parts pass the door every two or three minutes. The hotel is well known as one of the best in London, has excellent smoking and billiard rooms, swimming bath, &c., and special arrangements have been made with the proprietors for the accommodation of members at a reduced rate. The Committee think, therefore, that a better support ought to be given to the Club, and would urge upon its members the necessity of enlisting new candidates for membership. Subscription, two guineas per annum, no entrance fee. Any inquiries addressed to the Secretary as above will be immediately attended to."

— CABBAGES.—At one time Ellam's Early was my favourite spring Cabbage, but it had to give way to Mein's No. 1, which for spring and summer use is the only Cabbage I now grow. It hearts early and grows to a great size, and therefore remains for a long time in fit condition for use. In 1886 I sowed the seed on the 5th July, in 1887 on the 3rd, and this year on the 5th of the same month. It showed no tendency to bolt, and, were it necessary, I would sow earlier. Were I to grow only one variety it would be Mein's No. 1, and I could cut it every day all the year round. For spring I plant 1 foot apart, pull for use every alternate plant, and then every other row. I think it would be the Cabbage for the grower for market.—J. B. H.

— MR. THOS. SMITH, Henbury Hill, Bristol, writes:—"My experience of BEAUTY OF HEBRON AND READING RUSSET POTATOES during the past season agrees with that of Mr. J. Palmer, and I do not intend to grow either of them again. Of about a dozen sorts grown, Satisfaction and Best of All were all that could be desired for quantity, comparative freedom from disease, and excellence of quality when cooked. Sutton's Prizetaker, though rather badly diseased, gave such a heavy crop of tubers of first quality that it was far from being unprofitable."

— A CORRESPONDENT sends the following paragraph on OPHIOPOGONS:—"It is to be feared these are not so much known by cultivators as they should be, seeing how useful they are for decorative purposes. Recently, when looking over a large garden at Bagshot, my attention was drawn to a large plant of the Golden variegated Ophiopogon, growing in a 10-inch pot. It had from forty to fifty spikes of blue flowers. When seen in this state, the spikes rising above the long grass-like golden leaves, render it a most beautiful object. This plant was from 2 to 3 feet across, and the foliage covered the pot, adapting the plant for vases. I was informed that it had stood in the cold house when the frost was severe enough to freeze the pot to the ground. This proves the plant to be very hardy. The Ophiopogons are strong rooting plants, needing good holding soil and an open situation to secure bright, clean foliage."

— LILIUM AURATUM DEGENERATING.—Five or six years ago we bought 100 bulbs of this Liliun. Some were potted and grown for conservatory decoration, others were planted out in the bed of a greenhouse while others were planted in various parts in the open ground, and in almost every instance the bulbs have degenerated. I fear that their disposition to degenerate is very general. I have it on good authority that the sale of this Lily exceeds all others. They are bought largely as imported, and many more are purchased when seen in bloom in nurseries, so that of all Lilies this should be the most common and the best, but it is neither; and although I would not advocate its limited purchase or culture, yet no one need buy it under the impression that good bulbs will become better in their hands, or that once bought a grand annual display will be the result.—M. M.

— IN the report of the Superintendent of the ADELAIDE BOTANIC GARDEN for the past year it is stated that the Insect-powder Plant (*Pyrethrum cinerariaefolium*, *Trévir.*), roseum, and carneum, *Bibrst.*), and the Cheesemaker (*Withania coagulans*, *Dun.*), which were introduced into the Garden a few years ago, have found a congenial climate there, and have prospered wherever they were planted in the colony. Eland's Boontges (*Elephantorrhiza Burchelli*, *Benth.*), which has also been recently introduced, does fairly well. In winter nothing remains of

this plant but the roots, which contain tannic acid. A number of cuttings from the Daira Grape, a valuable species which comes from Almeria, have thriven wonderfully in the garden. There are now in the Palm house 180 species and varieties of Palms. The Museum of Economic Botany attached to the Garden has been enriched during the past year by 1795 articles, amongst the most remarkable of which was a collection sent by the Sultan of Jahore, one of the specimens being a sample of sugar prepared from the Cocoa-nut.

— MR. MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR OCTOBER.—Mean temperature of month, 45.3°. Maximum on the 26th, 65.2°; minimum on the 33rd, 24.2°. Maximum in the sun on the 7th, 106.2°; minimum on grass on the 6th, 18.2°. Mean temperature of air at 9 A.M., 45.4°. Mean temperature of soil, 1 foot deep, 46.9°. Number of nights below 32°, in shade ten, on grass twenty-one. Total duration of sunshine in month 99 hours, or 31 per cent. of possible duration. We had eight sunless days. Total rainfall, 0.64 inch; maximum fall in twenty-four hours on the 1st, 0.25 inch. Rain fell on ten days. Average velocity of wind, 7.6 miles per hour. Velocity exceeded 400 miles on three days, and fell short of 100 miles on thirteen days. A fine dry month, with very cold nights. The rainfall and mean minimum are both lower than any of the last twelve years. The last few days were very warm, and on the 28th the minimum was only 60°.

— THE WAKEFIELD PAXTON SOCIETY.—At the last meeting of this Society, held in their rooms, Mr. W. Hudson of Sandal read a very interesting paper on "Fungi and Fairy Rings." In the course of his remarks Mr. Hudson pointed out how restricted and unsafe were the popular conceptions in regard to the nature and qualities of the members of this lowly but ubiquitous section of the vegetable kingdom. Outside of the economical aspect of the subject they presented to the student a multitudinous array of forms and habits which could not but prove attractive to the inquiring mind. In the case of the aggregation of fungi, familiarly known as fairy rings, they had, up to very recent times, been surrounded with a halo of superstition, legend, and poetry. Mr. Hudson, however, traced out its life history in a manner which proved that in this, as in all cases where poetical and supernatural attributes were investigated, it had had to yield to the modern spirit of inquiry. There was a short discussion, and in conclusion a hearty vote of thanks was accorded to the essayist on the motion of Messrs. Bott, Bennett, and Garnett, who referred in eulogistic terms to Mr. Hudson's treatment of the subject. There was a good attendance of the members, over whom the President (Councillor Milnes) presided.

— IN a recent issue of *Nature* an interesting account of the FLORA OF THE KERMADEC ISLANDS is given, derived from the investigation of Mr. T. F. Cheeseman, Auckland, New Zealand:—"There are four islands lying at great distances apart, between 29° 10' and 31° 30' S. lat., and stretching in a south-west and a north-east direction; like New Zealand itself, the nearest point of which is between 500 and 600 miles distant. Raoul or Sunday Island is the largest and the farthest from New Zealand, being twenty miles in circumference, and about 640 miles from Auckland, and a little less than that distance from Tonga. Macaulay, the next in size, is sixty-eight miles to the south-west of Sunday Island; and Curtis and L'Esperance, still farther to the south-west, are little more than rocks. The expedition failed to land on the last-named island, and the visit to Curtis Island was of very brief duration, hence the botany relates almost exclusively to Sunday and Macaulay Islands. The group is of volcanic origin, and the greatest elevation in Sunday Island is 1720 feet, while Macaulay nowhere reaches quite half that height. Altogether Mr. Cheeseman collected 115 indigenous vascular plants, eighty-four being phanerogams and thirty-one cryptogams, and only five of them were regarded as endemic. In addition to the foregoing, twenty-six species of naturalised plants, chiefly European weeds, were observed or collected. Of the 115 indigenous species, no fewer than eighty-five are also found in New Zealand, though only fourteen of these are absolutely confined to the two localities. Forty-four species are found in Norfolk Island, forty of which also occur in New Zealand, and only two are apparently confined to Norfolk Island and the Kermadecs. Forty species extend to Lord Howe's Island, but thirty-four of these are also in New Zealand, and none of the peculiar plants of Lord Howe's Island reach the Kermadecs. Seventy-six of the species are common to Australia, sixty-three of them being also in New Zealand, and none of them otherwise peculiar to Australia. Lastly, forty-seven are found in Polynesia, and thirty-one of these also occur in New Zealand."

— **ASSAM AND ITS TEA GARDENS.**—The report of the administration of Assam for the past year illustrates the theory of the survival of the fittest. While the amount of land under Tea cultivation is increasing, the number of gardens is decreasing, owing to amalgamation and other influences. The average size of the Assam gardens is increasing year by year, showing combination among owners or more capital, and the small cultivators are disappearing. There were 883 gardens in 1886 and 873 in 1887, although new gardens were opened during the latter year. Even more was done in previous years to amalgamate gardens with a view to economy and convenience of working. The total area under Tea cultivation in 1887 was 950,171 acres, an increase of 16,037 acres over 1886. In 1882 the area of the gardens was 783,362 acres. These figures represent the areas held by the Tea planters, and either not yet worked at all or in one or other of the various stages between jungle and productive Tea garden. The area under mature plants last year was 177,900 acres, and under immature 33,179. The area under mature plants increases steadily in Assam; in 1882 it was 156,707 acres, 1885 159,876. The total Tea production of the province for 1887 is given at 68,451,180 lbs., an increase of 6,731,502 lbs., or 10·91 per cent. over 1886, and more than double the production of 1885. According to the figures of the Indian Tea Association, Assam produced 74·89 per cent. of the whole crop of Indian Tea in 1887. The yield per acre for the whole province was 385 lbs. for the year, as compared with 363 lbs. in 1886. The tendency of the cost of production is to decrease with the improved communications and methods of cultivation and manufacture. More is obtained from the soil at less cost; it is handled more cheaply and effectually, and reaches the consumer by more economical communications. The price is now lower than it ever was before, yet the planters are doing fairly well as regards profits. The explanation is that the Tea can now be turned out for less than was possible a few years ago. The use of machinery of an improved character is now largely extended, while freight and cost of transport are much less. The coolies are growing older and more skilled in their work, and can do more and far better than they could when raw hands. The Indian Tea Association estimates that Assam will produce 70,975,884 lbs. this year out of a total Indian crop of 95,829,312 lbs.—(*Tropical Agriculturist*).

WINTERING TUBEROUS BEGONIAS.

BEGONIAS in beds have succeeded well this season, considerably better than for the past three years, owing probably to the plentiful rain which fell during the June and July months. Last summer some of the old scarlet Pelargoniums, such, for instance, as Vesuvius, Tom Thumb, Triomphe de Stella, &c., completely eclipsed the Begonias for bloom, notwithstanding the very little growth they made, while this season just the reverse is the fact. We planted out in the first week of June, and from the first the plants grew freely, quickly filled the beds, and throughout the whole of summer have presented a very charming appearance, the scarlet and pink varieties having been especially fine, and they, judging by their vigorous appearance, would have continued so but for the 3° of frost registered on the morning of October 3rd. This, however, settled them. Begonias are about the first to suffer in this respect, yet, so long as the tubers escape, it is of little consequence about the tops. Ours having been cut down almost close to the ground, we are now busy preparing them for their winter quarters. Our practice is only in common with that of many, but as we scarcely ever lose a single tuber during the whole of their resting period, it may be of use to some to give details of our practice. In the first place the tubers are carefully dug up, leaving attached to each a moderate ball of earth. These in their sorts are then transferred to the late Peach house to gradually ripen. In about a fortnight we remove the soil from the top, by which time the latter, as a rule, part readily. We do not immediately after removing the soil commence to store them, but allow them to remain in the Peach house for a few days longer, so that the tubers may get fairly dry, but not at all shrivelled. Each sort is then packed in boxes according to their various sizes. For this purpose we use boxes which hold about 100 to 150 tubers. At the bottom of the boxes is placed about an inch depth of moderately dry leaf soil on which is a layer of tubers barely touching each other, then more leaf soil, and so on, until the boxes are filled. We then place them in a cellar safe from frost, and in this position they remain till spring, and the bulbs keep as firm and as fresh as possible. Where these plants are much appreciated it is desirable always to have a fresh stock coming on to take the place of older ones, and this is best done by annually sowing seed taken from some of the best plants grown indoors expressly for that purpose. And I need hardly say to grow them satisfactorily in beds, and especially in dry seasons, the beds must be deeply dug and have an abundance

of manure worked in, and during their growing season let them receive several good soakings of farmyard drainage water.—**H. MARKHAM, Mereworth Castle Gardens.**

TOMATOES AT MARSTON.

TOMATO crops have not been very abundant generally during the past season with regard to those grown in the open air, and the crop at the above garden has been no exception to the rule, although provision was made on rather an extensive scale for outdoor culture. But though the crop was thin outside, there has been a plentiful supply under glass, some grown in a heated pit and trained over close made hurdles proving very prolific. Fruits were cut from these that secured several first prizes at leading provincial shows. The fact of the light crops secured from open air plants suggested the idea of providing others for winter bearing, and I believe the success attending the effort on the part of Mr. Iggulden has been already given by him in the pages of the Journal; but as the Tomato provides a crop of considerable importance of the present day, a few further remarks thereon may not be inopportune. Those under notice were surplus plants not required for outdoor planting, for which object large numbers were prepared, but when it was found the open air crops were setting badly, these, instead of being thrown away, were potted and placed under glass to encourage a free growth, and eventually they replaced the Cucumbers that had done duty for the summer. They are stood on the old Cucumber bed and allowed to root through. The vigour with which they grow and their freedom of fruiting is simply remarkable. A quantity of fruit has already been gathered and many others maturing, while quantities are in various stages of development, and a good supply will thus be maintained throughout the winter months. The plants had been freely syringed, often twice during the day, this evidently proving effectual in securing a good set, for I noticed as many as eight or ten fruits in a cluster. They are very short-jointed too, a distance only of about 9 inches or so dividing the numerous clusters.

Free ventilation is of considerable importance in the production of good crops of Tomatoes in winter, a high and close temperature only encouraging a too free growth at the expense of fruits. Cold draughts, however, must not be allowed, and a good warmth in the pipes coupled with judicious ventilation maintains a healthy and buoyant atmosphere, which, together with frequent syringings already alluded to, is the course that Mr. Iggulden has adopted with such excellent results. In maintaining a healthy root action frequent application of artificial manures are applied to the surface of the pots, and I know of none that so quickly attracts the roots to the surface as Beeson's manure, although others may have an equally stimulating effect.

Mr. Iggulden confines himself to one variety only at this season, that being a good selection of Large Red, and he is of opinion that while there are many good varieties now to be had, this variety still holds its own for all-round purposes, and is especially adapted for winter fruiting. Carter's Dedham Favourite, Reading Perfection, and Hackwood Park Prolife are among the best for summer and exhibition purposes, these being fully represented at seasons other than winter.—**W. S.**

ROYAL HORTICULTURAL SOCIETY.

A **SPECIAL** meeting of the Council was held on Wednesday, October 31st, at 1 P.M., when it was resolved that a cordial vote of thanks be sent to all those who were kind enough to read papers, or to exhibit fruit, or in any other way to assist in making the late Apple and Pear Conference at Chiswick a success. It was resolved that a report of the Conference be forthwith prepared with a view to its publication as a number of the Journal of the Society.

The two resolutions passed at the Conference were then read and considered, and, with reference to the suggested Sub-Committee on Law and Parliamentary matters it was resolved, "That the Government having, at the suggestion of the Council of the R.H.S. and others expressly included horticulture in the Bill for the establishment of a department of agriculture, it would be unadvisable to appoint a separate Law and Parliamentary Committee, the Council considering itself to be in a position to fulfil the duties of such proposed Committee more advantageously than a subsidiary body."

With reference to the second resolution of the Conference, relating to the Society's gardens at Chiswick, the following resolution was passed—viz., "That the Council of the R.H.S. fully appreciate the value attaching to Chiswick Garden, and are anxious to extend and develop its resources to the greatest possible extent in every direction for the advancement of horticulture as far as the means placed in their hands will allow." It was further resolved, "To invite the members of the present Fruit and Floral Committees, and also the principal exhibitors, to attend a meeting in the Council room on Tuesday, November 13th, at 11.30 A.M., to discuss as to the best place in which to hold the fortnightly meetings for 1889."

It was resolved to hold a general meeting of the Fellows of the Society in the Council room on Tuesday, November 13th, at 2 P.M., in order to submit to them the draft of new bye-laws with a view to their adoption. It was determined that at the two next meetings of the Society, on November 13th and December 11th, any tender plants may be placed in the Council room, where they will be free from exposure to cold.

By kind permission of the Master and Benchers, a grand flower-

Show will be held by the R.H.S. in the Inner Temple Gardens on the 30th and 31st May 1889.

It was resolved to contribute £10 to the funds of both the Auricula and Carnation Societies if their exhibitions are held under the auspices of the R.H.S. in the year 1889.

NOTES FROM A HERTS GARDEN.

THE fruit season is over—*i.e.*, all has been gathered and stored of what we had of Apples and Pears worth mentioning, for of all my gardening experience (and it verges on half a century), the year has been the most disastrous to hardy fruit. Never, perhaps, was the promise of an abundant crop so completely frustrated as it has been in 1888. There was a glorious show of Plum, Pear, and Apple blossom. The east wind brought caterpillars innumerable. They ate the tender leaves and petals, even the embryonic fruit, the devastation being most complete as regards the Apple, but the Plum and Pear did not altogether escape the ravager; yet the former had the curved leaves indicative of aphides, and Pear foliage gave early symptoms of blister. Apricots were simply stripped of leaves by grubs. Peaches and Nectarines had the foliage blistered and infested with aphides. Plums against walls had neither grubs nor aphides to anything like the extent of those in the open. Cherries had a few aphides, and which came as usual on the points of the shoots. Figs escaped alike leaf-eating caterpillars and red spider.

Bush fruits were attacked by bullfinches, and sparrows began to play havoc with the buds of the Gooseberry, Red and White Currants, though we had the bushes dusted with quicklime whilst wet, but it did no good or only temporarily, yet it cleared the bushes of moss with which they were infested, and we shot the bullfinches and strung the bushes with black cotton, "best six cord, No. 20," an effectual barrier against the sparrows. We had no caterpillars; the Cuckoos kept the bushes free. In result we had a very full crop of Gooseberries and Currants, but of the latter fully half decayed through the continuous wet weather, and to keep any by matting or hexagon netting was practically excluded. Otherwise we have Currants for use with the October Raspberries. Black Currants swelled to an enormous size. Raspberries were neither good in crop nor quality. Heavy clay soil does not suit Raspberries, at least that is a convenient way of making an excuse when anything goes wrong—*i.e.*, it is the soil or the season, always something other than the treatment, and the fact in this case is the Raspberries had been strangled by Bindweed, and they are now recovering, have made very much stouter canes, and it is only sturdy canes with plump buds well ripened that afford fine fruit in quantity. I find mulching Raspberries with fresh manure about the time of flowering the best plan. Our summer Raspberries not being very good I took advantage of some rows of October Red, that were just as good as the summer were bad, to leave a 30-yards row for fruiting in summer, merely thinning the canes out, the other being cut down in the usual manner for late summer or autumn fruiting. The canes fruited well during the summer, and stood the wet better than the summer varieties, and the young canes are just as strong now (October 26th), and showing fruit equally free from the points of the canes as that of those that were cut down to the ground. In fact, there is not a particle of difference; both may fruit up to Christmas if the weather permits. As the October Raspberries fruit from the extremity of the cane, it is only necessary to cut away the fruited part, leaving the other for summer fruiting, and by cutting back or to the ground a portion of the canes we have strong canes for autumn.

Strawberries have been good in crop, not a plague of any sort having infested them. The fruit was late and dreadfully spoiled by the rain. We have tried nearly everything for keeping the fruit off the ground, and find nothing better than stable litter put between the rows and plants at flowering, or soon after. There is nearly sure to be a good rain to wash the virtue of the litter down to the roots and cleanse it sufficiently for the fruit to lie on. It answers its purpose as far as the fruit is concerned, and it is nearly all gone by autumn, and where it has gone the plants show by the plumpness of their crowns. It certainly has not been evaporated, or only by the Strawberry leaves, which have taken good care to store the assimilated matter or essence of the manure in the plants for the opening of another season's campaign of fruitfulness. We have several sorts—Black Prince, King of the Earlies, La Grosse Sucrée, Vicomtesse Hericart de Thury, Keen's Seedling, Sir Harry, Noble, Eureka, Mr. Radclyffe, James Veitch, President, Sir Charles Napier, and Dr. Hogg. Black Prince, King of the Earlies, and La Grosse Sucrée must be cut out, also Keen's Seedling, Sir Harry, Noble, Eureka, Mr. Radclyffe, James Veitch, and Sir Charles

Napier, which will leave Vicomtesse Hericart de Thury, President, and Dr. Hogg, which last I would also exclude, only I cannot do so on account of its British Queen flavour, and have instead Sir Joseph Paxton Those—*viz.*, Vicomtesse Hericart de Thury, President, and Sir Joseph Paxton are the best three croppers with quality as well, and Sir Joseph Paxton is very much the best in every way, of the three, both outdoors and forced. If confined to one Strawberry I should select Sir Joseph Paxton, and the reason it was not mentioned in the first place is because it deserves particular note for its freedom of growth, cropping, and usefulness. By having it on a south border in the open, and on a north border it can be had as long as most persons care to have Strawberries, and I put it forward as a crucial test whereby to get rid of so many varieties, which not only perplex the cultivator, but are from a profitable point of view cumberers of the ground. For forcing La Grosse Sucrée, Vicomtesse Hericart de Thury, President, Noble, Sir Joseph Paxton, Sir Charles Napier, and Dr. Hogg; of all those Sir Joseph Paxton, except for early work, is a long way the best.

Peaches and Nectarines outdoors are unprofitable so far as I can see. The trees on a south wall are not healthy; indeed, they are gummed; were blistered, aphid laden. On a west wall the trees are very much healthier, but the fruit has not near the size nor anything of the quality of that grown in a wall case with the same aspect. There was not a Peach worth the name this year outside.

Apricots do fairly well on a south aspect, Royal and Hemskerk being best; Kaisha and St. Ambrose are also good. Moorpark is very much gummed, very considerably more so than Peach, which is certainly one of the finest, if not the choicest, of Apricots. The blossom of Apricots were puny, and it set very badly. Then the "leaf-roller" came in force and denuded the trees of foliage. Picking and squeezing is very well to talk and write about, but it is quite another affair when you have to manage to get through two men's work with one pair of hands, and the labour question is really the "burning" one in gardens; besides it was no use last spring contending with the caterpillars, which not only stripped the fruit trees, but the majestic Oak and lightsome Ash were practically denuded of their first foliage. It is truly astounding to witness the might of numbers, and not less so the recuperative power of trees. Caterpillars do not live for ever—the trees rid of them per force of Nature—put forth foliage anew, so that there is some prospect of fruit another season, the Michaelmas summer clenching the argument in favour of the development of fruit buds and the maturity of the wood. As regards the Apricots, they are none the worse; indeed, they were over-luxuriant, and that the grub infection has counteracted, but I have no faith in Apricots ever being grown profitably in this country without means of entrapping the sun and retaining its heat inside a glass house. To grow fruit on the old lines—*i.e.*, without regard to cost of production is obsolete.—UTILITARIAN.

NEW CHRYSANTHEMUMS.

THE demand for novelties still continues as briskly as ever, and the nurserymen make corresponding efforts to obtain what the public require. It is well known that the continental growers are alive to this, but unfortunately, to say the least, they do not exercise the care in selection, naming, that purchasers have a right to expect. The consequence is that every season novelties received in this country necessitate a thorough trial before they can be recommended. This year we have already noted in one establishment several instances of this kind, and in both we believe the plants were received from M. Délaux. One of these was the variety Lincoln's Inn, recently certificated, which, as received here, is identical with Lakmé, sent out several years since. The other case was that of a so-called new Anemone, M. Castex, which is indistinguishable from Nouvelle Alvéole. We are not wholly free from such accidents in this country, for Marquis of Downshire, shown and certificated last year, seems to be simply the earlier dark stage of W. Robinson.

With regard to the Japanese varieties sent here from Japan and the United States, there appears to be a most lamentable confusion, and little doubt exists that some of these have received two, or even three, names. It is evident that the American introductions must be closely watched if our own nurserymen are introducing direct from Japan also, but the transatlantic importers have a great advantage. A gentleman who has had ample opportunity of ascertaining the accuracy of the statement, informs us that a large number of the American Japanese novelties are obtained from a lady in San Francisco. It is said that the

husband of this lady was for some years a resident in Japan, where he became one of the most successful amateur cultivators of the *Chrysanthemum*. Since his death the widow has resided in San Francisco, and numbers of seedlings raised in Japan have been sent to her at various

Comparatively few seedlings have been raised in this country yet, those obtained by several persons in recent years should have encouraged farther experiments. Messrs. J. Laing & Co., Forest Hill, were fortunate enough a year or two ago to procure some well selected and thoroughly

FIG. 49.—CHRYSANTHEMUM STANSTEAD SURPRISE.

times, these being distributed amongst the American tradesmen under numbers only, so that each one has named them as they flowered. Such a proceeding must necessarily lead to some confusion and the multiplication of synonyms.

matured imported seed, and from this they secured such favourite varieties as Mrs. J. Wright, Agnes and Bertha Flight, Album Fimbriatum, Stanstead White, and Alpha. From a subsequent batch they have raised several others, and one of these is Stanstead Surprise (fig. 49), a dis-

tinnet Japanese, certificated by the Floral Committee of the National Chrysanthemum Society on October 24th last. It has large blooms, the outer florets in the older examples drooping and curling, rich rosy crimson on the upper surface at first, fading to pink with a silvery reverse. The blooms come early on the crown buds, but they keep well, and some that have been out for fully three weeks have not lost all their charms yet. Terminal buds are coming later, and seem likely to be right for the shows.

CHRYSANTHEMUM WM. HOLMES.

THE enclosed bloom is one of seven, all the same size, grown on a plant under 3 feet high including pot, with good healthy foliage.

The bloom is much past its best, having been out over a month. However, I trust it will arrive in sufficiently good condition to enable you to form an idea of what it has been. Its measurement at the time of sending is, circumference $19\frac{1}{2}$ inches, height 5 inches. The box, unfortunately, is too small, but should it not arrive in fairly good condition, will be pleased to send you another. Should it be deserving of merit possibly you will mention it in your next issue of the Journal.—F. C. BARKER, *Ipswich*.

[The bloom arrived in good condition, and is an extremely fine example, the size being fully that given by Mr. Barker. The characters of the variety are also capitally displayed by 800 plants in Mr. Stevens' nursery at Putney, and the grower says as the result of his experience, "William Holmes must not be stopped." Upon stopped plants the blooms are much lighter in colour. The centre florets a kind of bronzy orange, quite distinct from a well-developed later bloom, which has the upper surface of the florets of the brightest crimson hue, the lower surface a beautiful golden bronze.]

CHRYSANTHEMUMS AT MAIDENHEAD.

TAKING an interest in Chrysanthemums, I called on Mr. Owen at the above nursery a few days since to inspect his collection, including many new varieties, all of which I saw a month previous in a very promising condition. Unfortunately, Mr. Owen's plants suffered terribly the early frosts, 13° being registered here on the night of October 2nd. A few plants only had been housed, some of the new varieties amongst them. This is the second year Mr. Owen has unluckily missed flowering several promising new seedling and other varieties through destruction of his plants, or at least their buds, by frost.

Of those now in flower, taking the Japanese as most numerous first, I noted two especially that promised to make large exhibition blooms—George Daniels, a new seedling variety, blooms 9 inches in diameter, the florets reflexed, and three-quarters of an inch in width, colour silvery white, the under side lined with deep rose; Fimbriatum, delicate pink, lighter centre, large distinct flower. Also very good were Florence Percy, milky white; Aleyon, rosy amaranth, silvery pink reverse, shape of flower resembling that of M. Freeman; Elsie, creamy white, very pretty; Avalanche, fine pure white; Gorgeous, deep yellow; Sarah Owen, the fine bronze sport from Madame J. Laing; Holborn Beauty, good lemon yellow; Anatole Cordonnier, of dwarf habit, flowers dark amaranth, with long narrow florets; Priscilla, salmon red shaded bronze; and Gordon, peach pink, pretty. A variety sent for trial, and named Miss Burgess, proved to be the old Japanese Bouquet Fait, odoratum, dark purple, highly scented.

A new reflexed variety, James Carter, bronzy yellow, promises to be an acquisition in this class.—C. H.

THREE USEFUL CHRYSANTHEMUMS.

WE have found the three following grown in quantity extremely useful for general decorative purposes during October, and many are still in good condition. Madame C. Desgrange, white; and G. Wermig, yellow; these two are well known. The third, Roi des Préoces (Jap.), dark crimson, makes a fine contrast; the flowers are not large, but are produced very freely, and the plant is of dwarf habit. Late-struck cuttings give good heads of flower on plants not more than 1 foot high in small pots.—C. HERRIN, *Dropmore*.

CANKER IN APPLE TREES.

I READ with interest the other day a discussion whether this canker is disease or the consequence of uncongenial soil and imperfect nutrition. I should be glad to give my experience of an Apple tree. Last autumn I had a young tree (Peasgood's Nonesuch) given me by a neighbour five or six years old. It was very badly cankered in six places. We transplanted it carefully. My garden, though adjoining, is very different in soil to that whence the tree came. We transplanted it early in October. Early work does best for us. We cut off the leading shoot, it was so badly cankered. From the other five places we cut out all cankered matter (in some very deep), then covered the spots with clay, enveloped it in brown paper, and tightly secured it to keep them free from exposure. This year the tree has borne well. We had thirty Apples on it, twenty of them fine specimens, and some of them on the cankered branches. I exhibited five at the Pomological Show in Exeter last month, and not only took the first prize in the class, but the Apples were pronounced the finest fruit in the Show.

We have since uncovered the diseased parts, and find them re-

covering health, and new bark forming over them. The tree looks healthy, the bark bright, and good promise for next year. We have followed the same plan again with the tender spots. I think these facts may be of interest in the study of this question.—HENRY BRAMLEY, *Uffculme Vicarage, Devon*.

CLETHRA ARBOREA.

It is surprising this valuable shrub is not more grown. Plants are seldom seen, and good specimens are rarely heard of, but it merits being classed amongst the best of half-hardy shrubs, and at this season I do not know any shrub, hardy or exotic, that can equal it in beauty and usefulness. We have several specimens here. They are grown in boxes like the Orange trees, placed in the open air with them in May, and brought into a cool house in October, and they succeed admirably with this treatment. Our largest plant is a little over 3 feet in height and 10 feet through, and when this tree is clothed with its beautiful white spikes of blossoms, as it always is in October and November, it is a most pleasing sight. It is commonly called the Lily of the Valley Tree, and the blooms are suggestive of that charming flower both in the spike, form, and fragrance. Our trees have been in bloom since September, and they will continue so for some time yet. Two years ago we planted a small specimen out in the open. The frost destroyed the points of the shoots, but the main stems were not injured, as they emitted young shoots freely in spring, and although it is not absolutely hardy, it is nearly so. Apart from this point it is such an excellent autumn and early winter-flowering tree for the greenhouse and conservatory that to grow it for the decoration of either of these structures will amply repay all cultivators.

Small plants flower freely, and in proportion a plant in a 6 or 8-inch pot will produce as much flower as one in a tub 4 feet square. They root freely, and a mixture consisting of loam, a little manure, and a quantity of sand will grow them well. They bear cutting. When in bloom we cut armfuls of flowers, with some wood attached, from them, and if a plant was becoming too tall it might be cut partially down with the result of securing a more bushy plant. We keep them somewhat dry in the winter, but water freely at other seasons. I have never known this Clethra to be infested with insects, and fighting against these is not an operation to be included in their culture. When grown in pots they should be placed out in the open air during the warmest part of the summer, as it is important that the wood should be well ripened before they begin to flower.—J. MUIR, *Margam, S. Wales*.

GRAPES SCALDING.

My best thanks are due to Mr. Combe for trying to set us right and clear away the difficulties respecting this important subject. Both Mr. Young and Mr. Riding are very anxious to bring me back to the point where they first differed from me. They evidently regard what they characterise as "fancy" and "pure theory" as a strong point in their arguments. I have no doubt that your correspondents would have been highly delighted with Mr. Combe's letter had he not added his last paragraph, in which he ventures his opinion "that all Grapes are liable to scald if proper precautions are not taken to prevent it." In my first letter, page 162, I said this would be the case if necessary precautions were not taken—the difference is not a great one. By continually carrying me back to this point your correspondents, with the exception of Mr. Combe, have clearly proved at least two things—first, that they have been relying upon somebody's theory or practice to carry them safely over the period when Lady Downe's is most likely to scald without taking the trouble to investigate the matter very deeply themselves. If they have succeeded, well and good. Secondly, by singling out Lady Downe's as an exception amongst Grapes that will scald, they have regarded the evil of scalding with this particular variety as constitutional. They wish to repudiate this, but the line of action they have taken leaves room for no other conclusion.

Had they not been so certain in flatly denying what I stated to be a fact, I might have given the grounds upon which I was warranted in making this statement—"It is no more difficult to scald the berries of Black Hamburgs and Madresfield Court than those of Lady Downe's," and I have since added all other varieties of Grapes. I venture to assert that the man who can render the conditions of a house suitable to scalding Grapes can also avoid such a catastrophe. Long ago I discovered how to do this with certainty. I did not experiment on a house of Grapes and run the risk of failure in maintaining the supply, but with a few that were provided for the purpose. The varieties tested were Black Hamburg, Foster's Seedling, Madresfield Court, Alicante, Alnwick Seedling, and Muscat of Alexandria, but the last I shall exclude because it failed to show bunches. Without it the list is a fairly representative one. The berries of every one of these scalded; the Alicante was the worst, then Black Hamburg, while Alnwick Seedling had the least number of scalded berries. Before this was tried I had grave doubts whether the scalding of Lady Downe's was constitutional or due to defective management. I have had no doubts on the subject since.

It has been highly amusing to note the conclusions at which your correspondents have arrived; they evidently believe that the Grapes I grow are in a pitiable condition by scalding, for in Mr. Young's last letter he advises me to alter my practice. At present I have no occasion to do so, and the illusory conclusion at which they have arrived may be removed when they are informed that during eleven years I do not think I have lost by scalding more berries than would amount to two good bunches, setting aside those subject to experiment, including this year, and although I have lost several berries I do not perceive one bunch that has been actually spoiled.

Until I consider Mr. Combe's letter I will leave the Grapes with which I am experimenting. It may be remembered by the observant readers of the Journal that I once ventured to think in a discussion on non-ventilating that early Grapes and Peaches could be grown as well without opening the ventilators as by doing so on the orthodox principle. This may be regarded as foreign to the subject of scalding, but such is not the case, for it bears very largely on that point that your correspondents are so anxious that I should clear up. I had tried the non-ventilating principle for Grapes and Peaches when I ventured to make that statement, but for the present I shall only allude to the Vines. The first season I tried it we commenced cutting on the 7th of May, and the season was a favourable one for this system of culture. Some young Vines were grown on the east side of the house (span-roofed) for fruiting the following season, and they made splendid wood and particularly large leathery foliage. These young Vines did remarkably well the following season, but the season was a very different one, much brighter and warmer, and not so favourable for carrying out non-ventilation with safety. All, however, went well until the stoning period, when the berries scalded badly. Slight shading has been tried during this critical period, and yet scalding took place. No harm occurred to the foliage or Grapes before or after the stoning period, and the temperature was as high by sun heat, and as moist before, and often higher afterwards. Condensed moisture was on the berries in the morning on many occasions during stoning, before and after, but harm only was done during the time of stoning. The small globules of water disappeared from the berries as the temperature rose, and I concluded were absorbed by the atmosphere. Thus the conclusion that scalding might occur by the vapour being overheated and the Vines being overforced at that particular time.

For the present I will leave them to look at Mr. Young's last letter, for he says I have had my answer in his statement that it requires "gross carelessness" to scald the Black Hamburgh. I have said before, that if this is the case it is equally so to scald the berries of Lady Downe's. Mr. Riding jumps at the conditional admission I have made him as a strong point attained. The condition of admission is that it is "gross carelessness" to scald Lady Downe's. What do you gain? Mr. Young asks me to carry out, however, in the last four lines of his letter to prove his point what I should regard as "gross carelessness" in the management of Lady Downe's or any other Grape during the critical period of stoning. He wants me to bring about a condition I have repudiated more than once, and strikingly so in my last letter. I cannot perceive any treatment more calculated to scald Grapes. It is the results that follow such treatment that bring about the evil that I have been trying to warn cultivators to avoid.

Mr. Riding tried to show that Mr. Simpson was wrong because he agreed with me that Black Hamburgs would scald, and he added particularly in a cool house, or where very little fire heat was used. I fully agree with Mr. Simpson, and I should look for scalding under these conditions, because considerable moisture would be condensed on the foliage and berries at night, and the anxiety of the cultivator to take every advantage of the sun to hasten forward his crop would thus bring about the conditions Mr. Young wishes me to try, and the cause that scalded the berries on the Vines subjected to the non-ventilating principle as well as those experimented upon.

I said on page 320 the condensation of vapours may be due to three causes—cooling, compression, and chemical affinity. I gave briefly condensation by the first, because I firmly believe that moisture on the berries is deposited more frequently by this means than any other. To avoid even this state of things I have twice advised the raising of the night temperature with the most liberal ventilation during the day. Although I think no harm results from moisture being condensed on the berries, I wished to direct cultivators to avoid at that critical period such a state of things as far as possible for fear of the evil consequences that might follow any mismanagement in ventilation. Although we have the Vines under artificial treatment, I do not see that the accepted law of condensation and evaporation need be upset. If we grow Vines without opening the ventilators condensation by compression takes place. The berries will stand this before and after the stoning period, but not while they are stoning without the berries scalding. My idea is, and what I intended to convey, by harm resulting from the artificial treatment to which Vines are subjected in my last, was negligence in not encouraging evaporation to go steadily on as the temperature increased. Heat being the agent of all evaporation, I believe the conditions of the atmosphere externally at the season of the year when Lady Downe's is stoning to be highly favourable to promote rapid evaporation. The cultivator has also within his power the chance of changing quickly the atmosphere of the house. The quantity of vapour in the atmosphere externally at the time might favour or retard evaporation; but, in most cases the former. At that season of the year, with careful management, the Grapes need not be subjected to a thorough "sweating" after the temperature has commenced rising.

I agree with Mr. Combe that a slightly drier atmosphere in the house is an advantage; this, combined with the night temperature, I have advocated, and liberal ventilation from early morning until the temperature has declined sufficiently for closing would render Grapes safe against scalding. It is this condensed moisture that cannot be evaporated from the berries that ends in scalding when the Grapes are grown without ventilation. This was the means by which I succeeded in scalding Grapes. It is not necessary to keep the berries subjected to such artificial treatment for any great length of time each day to accomplish this thoroughly. I have observed even early in the season when the atmosphere has been changed by the admission of air that the moisture deposited on the berries soon disappeared and they became dry as far as I was able to detect.

This "sweating" system does not injure the leaves or the berries before or after stoning; in fact, the foliage does not suffer during stoning while the berries scald. I am therefore willing to admit that if the berries "stewed" as I stated they would be equally liable to do so in any stage, the foliage as well. Cucumbers grown on the non-ventilating system are covered the whole day through with moisture, and I have often seen it drop off them. During the hot weather of last July what was formerly the stove here had Cucumbers in it, and when the door was opened vapour could be seen rushing out like a cloud of smoke. At times the house was quite misty from the amount of vapour in the atmosphere, and yet the foliage and Cucumbers took no harm. The fruit was certainly much lighter in colour than those grown under more natural conditions. Let the atmosphere once become dry, if only for a very short time, and the foliage will not be long before it is scorched.

The temperature rising by sun heat while the house is closed cause condensation to take place in consequence of the pressure of the atmosphere; the moisture on the berries becoming heated through slow evaporation is not to my mind the sole cause of scalding. This, combined with the conditions that bring about this state of things prove too forcing for the Vines at that particular time. If not, perhaps Mr. Combe or somebody else can explain why Grapes are an exception in this respect.

Now for the syringing. Why did I qualify the statement by saying "I do not believe in such a practice, because it is liable to injure the bloom?" For this simple reason, because I have always succeeded in keeping down red spider without following any such plan, but more particularly because the water that has to be used in many gardens is of such a nature that it would leave a deposit on the berries and spoil their appearance. I could not recommend the practice generally, because I know the water is of such a nature that, while one might do it with safety, a score or more might and would spot the berries. The Grapes I saw, and to which I alluded, were perfect enough as regards the bloom, and I did not observe that any of them were spotted.—WM. BARDNEY.

CULTIVATION OF THE PEAR ON WALLS.

[Read by Mr. A. Pettigrew at a meeting of the Young Men's Improvement Society in the Castle Gardens, Cardiff.]

THE Pear can be had, by proper selection of varieties, in good condition for dessert for eight months in the year. The tree will grow in almost any kind of soil, but it attains the greatest perfection in a deep rich well-drained loam, and if other conditions are favourable, it will continue to be fruitful and in vigorous health for fifty years or more if properly attended to. Standard trees growing in open quarters live to a much greater age than wall trees, and continue to bear good crops for nearly 200 years; but the fruit, as a rule, is not so good in quality, nor the crops so certain, as those from wall trees.

The best situation for the Pear is one having a south aspect. If the soil is inclined to be wet it must be thoroughly drained, and if exposed to storms, it may be sheltered by means of plantations at some little distance off. In making wall borders they should be as wide as the wall is high; they may be broader or narrower according to circumstances, but, as a rule, they should never be less than the height of the wall, and 3 feet in depth.

Pears can be grown successfully on south, east, west, and north walls (by a proper selection of varieties) but not on a north aspect in the north of England, nor in Scotland, where the climate is too cold and damp for them.

Plant the choicer varieties in the south, and the early varieties in north aspects, but by planting a few early varieties in the south, east, and west aspects, the season of the particular varieties thus planted will be prolonged by those growing in the north, which will ripen much later than the others planted in the aspects mentioned.

The south, east, and west aspects are good, and may be planted with the best varieties, and the late keepers which take a long time to ripen after the fruit is gathered and stored. For example, the walls in the garden here are covered with two or more of the following varieties, and the trees, with the crops they bear annually, will compare favourably with trees of the same varieties growing in any garden in the country.

Trees on south aspect—Beurré Diel, General Todleben, Bergamotte Esperen, Marie Louise, Beurré Bosc, Glou Moreceau, Beurré

Magnifique, Easter Beurré, Williams' Bon Chrétien, Pitmaston Duchess, Beurré d'Amanlis, Jargonelle, and others. West aspect—Pitmaston Dnehes, Beurré Del, Brown Beurré, Gansel's Bergamot, General Todleben, Doyenné du Comice, Easter Beurré, Jargonelle, Louise Bonne of Jersey, Beurré d'Amanlis, &c.

North aspect—Jargonelle, Louise Bonne of Jersey, and some others which are not suitable for the position, but which were planted partly to cover the wall, and to train trees to plant elsewhere. The Jargonelle and Louise Bonne of Jersey do fairly well, and I have no doubt Beurré d'Amanlis and some other early varieties would do equally well, and lengthen the season of these varieties considerably.

In selecting the trees ascertain the number required, and write a list of the varieties which you intend to plant, and select them for yourself in the nursery. Maidens worked on the free stock, one year from the bud, are preferable to two and three years old trained trees which have been cut back several times in the nursery to keep them small and in saleable condition. See that they have straight clean growths with plump buds and well ripened wood, and that the scion and stock are perfectly united.

The trees should be lifted as carefully as possible not to injure the roots, and packed immediately after to keep the small fibrous roots from drying, and planted in their permanent quarters as soon after as possible. Before planting cut off the ends of any of the injured roots, and the extra strong ones shortened to induce them to send out fibrous roots, which are better for nourishing the tree than strong tap roots that penetrate deeply into the earth. Level the surface of the border before planting, especially at the bottom of the wall. If this is not done at first there is a probability when the trees are planted of some of them being deeper than they should be when the border is levelled afterwards. In planting fruit trees young gardeners are apt to make a mistake in planting them too deep through inexperience. As a rule they must never be planted deeper than they were when growing in the nursery lines, and the stem not less than 5 or 6 inches from the bottom of the wall to allow of it swelling afterwards. Make the hole large enough to allow of the roots being spread out to their full length all round, and fill the soil in carefully to the top before it is tramped. After it has been firmly trodden all over and levelled mulch the surface with manure to exclude air and to prevent evaporation from the soil. Prune the trees to a good bud about 14 inches from the ground, and then make secure to the wall. The best time to plant is as soon as possible after the leaves have fallen in the autumn, but planting may be continued in good weather from then on to the middle of March.

To grow handsome fruitful trees they require a great amount of attention in training when young, and no one need expect to succeed in forming well-balanced trees unless this is done, both in pruning, nailing, stopping lateral shoots, and disbudding, until the trees have furnished the walls with branches. Good maiden trees with well-matured wood will produce from four to five branches the first year after planting.

If the branches are well placed, they may all be retained, taking the one in the centre for a leader, and the other four, two on each side, to form the base and permanent branches. There are several modes of training the Pear tree on walls, but I prefer the fan-shape to all other methods practised, both for appearance and fruitfulness. In nailing or tying the branches, care should be taken to give them plenty of room to swell. I have known many trees ruined when young through the young men nailing them too tightly. They never thought of making sufficient allowance for the branches to develop, and the string or shreds cut through the bark and rendered them useless.

In training when the trees are young all the branches must have an upward tendency for a few years before they are placed into their permanent positions. When nailed into their proper places at once it retards the flow of sap in the lower branches, weakens them, and injures the whole tree by the leader and upper branches absorbing the sap and causing them to make strong gross unripened wood, which is useless for building up a fruitful tree.

The leading shoot should be pruned to 14 inches or more from where it started, according to its strength, and a nick cut through the bark above each of the side buds required to form branches to induce them to break into growth. The permanent branches should never be cut back unless the tree is bare at the bottom or the wood at the extreme end of it is not thoroughly ripened, or if it happens to be a fruit bud at the end, which is often the case, it is then cut back to a prominent leaf bud and well ripened wood.

In the spring after the trees have started into growth examine them carefully, and all the buds on the leaders which are not required may be rubbed off. If more than one starts from the terminal bud of the permanent branches remove all except the strongest one and two or three of the buds on the branch imme-

diately behind it taken off as well to strengthen the terminal growth.

As the shoots grow nail them in to prevent their being broken by wind. A tree may be built up very quickly if it makes strong healthy growth early in the season by stopping the leading shoot, after the wood is about three parts ripe to 14 inches in length, when it will throw out a double set of branches and a new leader in one season, and ripen them well, if the weather continues good. But, as a rule, it is not advisable to adopt this method with all trees, nor in all seasons. If the trees in the second year after planting are inclined to make too vigorous growths they must be lifted carefully and root-pruned, which will check the growth and bring the trees into fruiting, after which they will not require root-pruning for a long time.

The building up of a tree consists in pruning the leader and training the new branches until the wall is covered, and in stopping lateral growths or breastwood during the summer, and pruning them in autumn when the leaves have fallen to within two buds of the branches to form fruit spurs. If the trees become infested at any time with scale, which they are subject to, they should be syringed with a mixture of petroleum and water, which will kill it without injuring the trees if done soon after pruning, or at any time during the winter when the trees are dormant.

To make sure of obtaining a crop of fruit the trees may be protected during the time they are in flower, and also when the fruit is nearing maturity, against the attacks of birds.

Mulch the border at the bottom of the wall with rough litter from the stable all the year round. It is good for the roots of the trees, and it is better for walking on in all seasons than the bare earth.

PRUNING FRUIT TREES.

It was with great interest that I read in last week's Journal the remarks on the above subject at the Chiswick Fruit Conference by Mr. Shirley Hibberd, and it is practically the key of profitable fruit culture in this country as much as suitable varieties or good soil. In common with other gardeners I have been very much impressed by the ignorance displayed by many gardeners in pruning fruit trees, their ideas on this subject being next akin to "pollarding." Remarks of this nature are generally attributed to the young gardener, but I think a large percentage of the "old" may be placed in the same category. Of course, whether the trees are Apples, Pears, or Plums, the trees must be pruned during the first few years of their existence, as explained by Mr. Bunyard, so as to lay the foundation, but after that each variety will attain a contour peculiarly their own, with a little rational pruning occasionally to balance growth or to prevent crowding. With Gooseberries a course of pruning is necessary, but this must not be carried to the extent as practised by many gardeners. The best course with these is to encourage as much young growth as possible, cutting out all old bearing wood where it can be done with advantage, so as to allow light and air to play amongst the branches, and to allow free access for gathering. A clear stem must be encouraged, "sucker" growth being very objectionable to the Gooseberry. With Black Currants a continual supply of young wood must be encouraged up from the bottom, merely cutting out old and exhausted wood, or to keep the trees open.

—A. YOUNG.

CHRYSANTHEMUM SHOWS.

WE shall be obliged if those of our friends who favour us with reports of shows will, as far as is practicable, give full list of varieties in the first prize stands in the chief classes.

HAVANT.

THE fifth Exhibition of Chrysanthemums, fruit and vegetables was held at Havant on Wednesday, 31st ult., and, notwithstanding the defects of the growing season, proved to be the most successful Show held by this Society. The Havant Show always has additional interest in the splendid collection of vegetables and fruit which form a separate show, and materially add to the popularity of the Society in the district. Japanese Chrysanthemums were fully up to the average of former years, while the incurved showed a marked advance. Other sections were not quite so good.

Among the Japanese many fine specimens were staged of such varieties as Martha Harding, rarely seen so fine; Avalanche, Florence Percy, Edwin Molyneux, Mr. Garnar, and Mdle. Lacroix. Many complaints are heard of the blooms damping, which seems to be general throughout the country this season. It is to be hoped that after the shows are over some discussion may take place as to the probable causes of this.

In the class for groups of Chrysanthemums some remarkably fine banks were arranged, the quality being good throughout. Mr. W. Roberts, Havant, was first, closely followed by Mr. W. S. Moseley, gardener to John Taplin, Esq., and Mr. J. Agate, florist, Havant. The date of the Show proved too early for specimen plants, and only brought one exhibitor, Mr. N. F. Fuller, The Gardens, Idsworth. The loss to the Show in this respect was fully made up by the pretty and interesting group of Pompons, in which there was a sharp competition,

Mr. J. Agate securing the first prize, followed by Mr. W. Roberts and Mr. H. Garnet.

In Class 1, for twenty-four cut blooms, distinct, twelve Japanese and twelve incurved, the premier award fell to Mr. C. Penfold, gardener to Sir F. Fitzwygram, Bart., Leigh Park, who staged fine massive blooms. Mr. A. Payne, gardener to Mrs. Smith, Emsworth, being a good second, and Mr. W. C. Moseley, third. For eighteen cut blooms Messrs. W. Roberts, J. Agate, and W. Covell, gardener to J. A. N. Martin, Esq., West Leigh, secured the prizes in order named. Twelve Japanese, distinct, first, Mr. A. Payne; second, Mr. C. Penfold; third, Mr. W. Moseley. Twelve incurved, distinct, first, Mr. C. Penfold; second, Mr. W. Roberts; third, Mr. W. C. Moseley. Twelve Anemones, six varieties, first, Mr. R. Woodfine; second, Mr. W. Roberts; third, Mr. N. F. Fuller. Twelve reflexed, six varieties, first, Mr. C. Penfold; second, Mr. W. C. Moseley; third, Mr. A. Payne. Twelve Japanese Anemones, four varieties, first, Mr. C. Penfold; second, Mr. A. Payne; third, Mr. W. Moseley. Twelve sprays Pompons, first, Mr. W. Roberts; second, Mr. J. Agate; third, Mr. N. F. Fuller. Various smaller classes were all well filled, Mr. J. Horril showing exceedingly well.

For collections of vegetables, eight distinct varieties, Messrs. W. Long, F. Suter, and S. Solomons took prizes in order named. Special prizes offered by Messrs. Sutton & Sons, Reading, brought a spirited competition, the awards going to W. Salt, F. Suter, and N. F. Fuller. Special prizes offered by Messrs. Davis & Jones, Camberwell, proved an interesting feature, being for best single specimens of certain varieties, Miss Annie Lowe being well shown by J. Horril. Only one bloom was shown of Edouard Audiguier, but several very fine blooms were staged of Florence Percy, which attracted much attention.

SOUTHAMPTON.—NOVEMBER 1ST AND 2ND.

THIS Society as usual held its annual Exhibition in the Victoria Skating Rink, a capital building for the purpose, being light and agreeably warm for the various kinds of exotics exhibited. Notwithstanding the conditions under which the schedule was issued—namely, that the prizes would be paid in proportion to the amount of the receipts, a splendid show was the result, thus proving that exhibitors have the interest of this popular southern Society at heart. Considering the earliness of the date and a late season the Show was remarkably good, competition being unusually keen in the cut bloom classes, while the specimen plants and groups left little to be desired. Apples and Pears showed a decided falling off in numbers owing to the season. This defect was amply atoned for by the large array of Grapes exhibited, all being of good quality, some especially so. Vegetables were, as they always are at Southampton, a splendid show, while groups of plants and other miscellaneous classes were well filled. The Show was crowded with visitors as soon as it was opened. Excellent order prevailed thanks to Mr. Fuidge, ably assisted by a good working Committee.

Plants were arranged down one side of the Rink in a sloping bank, causing an effective display, while the groups were arranged at the end. For the best collection of Chrysanthemums, arranged for effect, occupying a space 10 feet by 6 feet, there was only one entry from Mr. G. Beesby, gardener to F. Willan, Esq., Thornhill Park, Bitterne, Southampton; the plants were dwarf, carrying large solid blooms with good foliage and well arranged. For a collection occupying a smaller space, 7 feet by 6 feet, Mr. Osborne, gardener to J. Buchan, Esq., Southampton, was easily first, the plants were very dwarf in the front, while those at the back reached only 4 feet 6 inches high; good foliage and bloom combined with a neat arrangement completed a meritorious group. Mr. J. Jones, gardener to C. A. Day, Esq., Terrace House, The Polygon, was a good second. For four plants incurved or reflexed, also for four specimens distinct varieties, also for a single specimen Japanese, Mr. E. Wills, gardener to Mrs. Pearce, The Firs, Bassett, Southampton, took leading honours with specimens, large, well trained and well flowered, although some few required a little more time to develop their blooms, Dr. Sharpe being most conspicuous for its quality. For four Japanese plants, distinct varieties, Mr. W. Joy, nurseryman, Shirley, Southampton, was an easy first with grand specimens of Madame Bertie Rendatler, Bouquet Fait, and Lady Selborne, fully 5 feet through, and covered with flowers.

CUT BLOOMS.—These formed the most imposing part of the Show. The competition was very spirited, over 1000 blooms being staged, while for the earliness of the season the quality was very good. In the leading class for twenty-four blooms distinct varieties, twelve incurved and twelve Japanese, eleven growers competed for the first prize of £5. Mr. E. Molyneux, gardener to W. H. Myers, Esq., J.P., Swanmore Park, Bishop's Waltham, was easily first, staging in his accustomed style grand blooms of Japanese varieties, while the incurved specimens were solid, fresh, and well finished, though not over-large. The stand of Japanese blooms was remarkable, four first-class certificates to new varieties in it, while in addition it contained the premier bloom of the Show in any section, a grand specimen of Edwin Molyneux, 7½ inches wide and 6½ inches deep, richly coloured. Commencing with the back row, and reading from left to right, the Japanese blooms staged were Edwin Molyneux, Baronne de Prailly, Frédéric Marrouch, Madame C. Audiguier, Avalanche, Val d'Andorre, Madame Laing, Mrs. Falconer Jameson, Golden Dragon, Mr. H. Wellam, Boule d'Or, and Florence Percy. Incurved: Empress of India, Lord Alcester, Alfred Salter, Queen of England, Lord Wolseley, Jeanne d'Arc, Golden Empress, Prince Alfred, Lady Hardinge, Mr. Bunn, Nil Desperandum, and Mrs. W. Shipman. Messrs. W. & G. Drover, Fareham, were second, staging large, full, but rather uneven Japanese, the incurved generally full

and well staged. Lady Carey was very large, Mrs. W. Shipman very fine, Nil Desperandum clean and solid. Edwin Molyneux, Boule d'Or, Avalanche, and Mlle. Lacroix were especially noteworthy. Mr. W. Allen, gardener to Sir G. Russell, Bart., M.P., Swallowfield Park, near Reading, was third; Mr. G. Inglefield, gardener to Sir J. W. Kelk, Bart., Tedworth House, Marlborough, was fourth, both showing well. For twenty-four blooms in not less than twelve varieties, eight competed, Mr. Molyneux being again easily first, staging half incurved and the remainder Japanese. The former were Empress of India (2), Golden Empress (2), Alfred Salter (2), Queen of England (2), Lord Alcester (2), Prince Alfred, and Jeanne d'Arc. Japanese: Edwin Molyneux (2), Avalanche (2), Golden Dragon (2), Madame C. Audiguier (2), Val d'Andorre (2), Florence Percy, and Frédéric Marrouch. Mr. W. Neville, gardener to F. W. Flight, Esq., Cornstiles, Twyford, Winchester, was second, Prince Alfred, Lord Wolseley, and Jeanne d'Arc being particularly fresh and well finished among the incurved, Avalanche and Edwin Molyneux being the best among the Japanese; Mr. W. Allen was third. For twelve incurved, distinct varieties, six staged, Mr. G. Inglefield leading the way with Jeanne d'Arc, Empress of India, Queen of England, Golden Empress, Princess Teck, Novelty, Lord Alcester, Beethoven, White Beverley, Refulgence, Venus, and Mr. Bunn. Mr. C. Warden, gardener to Sir F. Bathurst, Clarendon Park, Salisbury, was second; Mr. J. Snow, Wadhurst Park, Sussex, third. For twelve Japanese, distinct, eleven staged, making a good display. Mr. Inglefield led the way with even fresh well staged blooms of Criterion, Madame C. Audiguier, Soleil Levant, Baronne de Prailly, Balmoreau, Thunberg, Edwin Molyneux, Fair Maid of Guernsey, Maiden's Blush, M. Freeman, Elaine, and Belle Paule. Mr. C. Brooks, gardener to H. A. Simmonds, Esq., Red Rice, Andover, was second, staging even clean blooms; Mr. Snow third. For twelve Anemone flowered nine competed, Messrs. Drover being easily first with blooms well up in the centre of Laing's Anemone (2), Minnie Chate, Lady Margaret, Nouvelle Alvéole (2), Gluck (2), Jean Marty, Margouline (2), and Sœur Dorothee Souille. Mr. Neville was a good second; Mr. Snow third. For the same number of reflexed varieties Mr. W. Allen had the first of four lots, staging Amy Furze, King of Crimson (2), Madame Madeline Tezier, Dr. Sharp, Phidias, Chevalier Domage, Alma, Cloth of Gold, Cullingfordi, Emperor of China, and Distinction. Mr. C. Brooks was second; Mr. T. Osborne third. Mr. C. Brooks had the premier award in the maiden class for twelve blooms, staging well. For twelve blooms, not more than two of any variety, seven competed, Mr. E. Wills being first with a good stand; Mr. T. Annells, gardener to C. Shenton, Esq., The Glen, Winchester, second; Mr. H. Drover, Ventnor, Isle of Wight, third.

Amateurs staged good blooms in their respective classes, Mr. R. Carter, St. Denys, Southampton, being the most conspicuous. For the most elegant glass stand or epergne dressed with Chrysanthemums and other flowers, ladies only, Miss Flight was first with a light arrangement of flowers, foliage, and grasses evenly disposed; Miss Chamberlain, Southampton, was second, Mrs. H. Brodie third.

Mr. W. Colchester offered a special prize for a specimen Chrysanthemum, to be grown with Ichthemic guano. Mr. W. Joy staged a magnificent one of Lady Selborne, 5 feet in diameter, covered with blooms of good quality. Messrs. W. Wood & Sons offered a silver medal for six cut-back Chrysanthemums, to be fed with their liquid manure powder. Mr. Busby obtained the award. Mr. Wills arranged the best miscellaneous group of plants, a light one; Mr. J. Amys, gardener to Hon. Mrs. Elliott Yorke, Netley Cliff, second. Mr. Osborne had the best collection of Orchids. Table plants, Palms, Cyclamens, were all well represented.

First-class certificates were awarded to Mr. Molyneux for the following Japanese Chrysanthemums:—

Avalanche.—Pure white, full rounded flowers, remarkable for the solidity of the florets, which are narrow, some being split at the edges; the bloom measured 7 inches across and 5 inches deep.

Mrs. Falconer Jameson.—Florets broad, strap shaped, the under side pale gold, the upper surface orange bronze; bloom 7½ inches in diameter and 5 inches deep. The plant grows only 3 feet high.

Florence Percy.—Florets waxy white, exquisitely cut at the edges. A full bold flower 5 inches deep, the bottom florets drooping in a most graceful manner, described by the ladies as "quite a gem."

Frédéric Marrouch.—A large full flower, having long fluted florets rich deep yellow. A grand acquisition to the back row varieties, superseding Soleil Levant, 8 inches in diameter.

Jean Marty (Drover).—A Japanese Anemone, deep lilac centre, which is very high, large, and full; the guard florets paler; distinct, and effective.

FRUIT.—The display was imposing, especially the Grapes, which were throughout of excellent quality. For three distinct varieties, one bunch of each, Mr. C. Warden staged a grand lot among nine entries. Muscat of Alexandria was perfect in every way; Gros Colman, large in bunch, berry, and well coloured, and Gros Guillaume. Mr. T. Hall, gardener to S. Montagu, Esq., M.P., South Stoncham House, was second, and Mr. W. Allen third, both staging well. For three bunches of black Grapes Mr. Molyneux led the way with Alicante, extra large berries and shapely bunches. Mr. Hall followed with large loose bunches but smaller berries, finely finished; third, Mr. J. Chalk, gardener to G. Reach, Esq., Westwood, Salisbury. Eight competed. For the same number of white bunches Mr. Molyneux was easily first with good Muscat of Alexandria; Mr. J. Smith, gardener to Lord Montagu, Palace House, Beaulieu, second. Mr. H. W. Ward, gardener to Earl Radnor, Longford Castle, Salisbury, had the heaviest bunch, Gros Guillaume, about 7 lbs.

Mr. Snow following. For two bunches of black Grapes, Mr. R. Balchin, gardener to H. Sholto Douglas, Esq., Noorlands, Bitterne, was first with Alicante, very fine shapely bunches, grandly coloured. Mr. C. Warden second. For two bunches of white, Mr. J. Budd, gardener to F. Dalgely, Esq., Lockesley Hall, Romsey, was first, Mr. Warden following. Mr. G. H. Richards, gardener to the Earl of Normanton, Somerley, Ringwood, staged the best Pine Apple, a good one of Smooth Cayenne. Mr. G. Lock, Crediton, Devon, followed. For three dishes of dessert Apples, distinct kinds, among six entries, Mr. G. Pragnell, gardener to J. D. W. Digby, Esq., Sherborne, Dorset, was first with Worcester Pearmain, King of Pippins, and Cox's Orange, well coloured; Mr. R. West, gardener to J. R. Wiggram, Esq., Northlands, Salisbury, was a close second. Mr. Hall had the best four dishes of Apples, distinct, either kitchen or dessert, with large handsome fruit. Mr. Pragnell staged best four dishes of Pears, distinct, followed by Mr. C. Curtis, gardener to J. S. Dixon, Esq., Brintons Road, Southampton.

VEGETABLES were a strong feature of the Show. For eight distinct varieties Mr. Pragnell was first with a fine collection. Mr. W. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Newbury, a close second. For six distinct varieties ten lots were staged. Mr. Inglefield led the way with good produce, with the remarkable incident of not having any Potatoes; Mr. Molyneux followed. Several exhibits, not for competition, were staged. A collection of Chrysanthemums cut and arranged like Dahlias, single, with Ferns and Palms from Messrs. Keynes, Williams & Co., Salisbury, was much admired. A collection of plants from Messrs. Cutbush & Son, Barnet Nurseries; fifteen dishes of Pears from Mr. W. Wildsmith, all of good quality; five Pine Apples from Mr. Ward, all tended to the attraction of the Exhibition.

THE SURREY CHRYSANTHEMUM SOCIETY.—Nov. 5TH AND 6TH.

THE fifth annual Exhibition of this Society was held in the Peckham Town Hall, Rye Lane, on Monday and Tuesday last, when there was a fair number of exhibits, but the cut blooms were not of first rate quality. Some of the classes were for fifty varieties of any section apparently, and the kinds had a rather mixed appearance. There were a few good stands of incurved, but the Japanese were the best represented. Some of the leading exhibitors were Mr. F. Sadler, gardener to Mrs. Lambert, Oakhill Place, Streatham; Mr. J. Heald, Peckham, from G. R. Parker, 13, Heron Road, Herne Hill; and Mr. D. Agate, gardener to Mrs. Walton, Woodlands, Peckham Rye. One of the best stands in the Show was the premier twelve Japanese from Mr. T. Sadler, the varieties being—Back row: M. Tarin, Elaine, Japonaise, Belle Paule. Middle row: Mdle. Lacroix, Curiosity, Peter the Great, Val d'Andorre. Front row: Soleil Levant, M. J. Laing, Mad. J. Laing, and Mr. W. Holmes. All were high, of good size and colour. The best group of Chrysanthemums was shown by Mr. W. Dickens, The Palatines, Champion Hill, being first in the class with well arranged plants bearing good blooms, both Japanese and incurved. A few non-competing exhibits were entered, including a stand of blooms from Messrs. Davis and Jones of Camberwell. This Show is essentially a metropolitan one, and the district is not one of the most favourable for plant cultivation, but there is still room for improvement in the quality of the exhibits, judging by what has been accomplished by amateurs in the Lambeth Society.

KINGSTON-ON-THAMES.—NOVEMBER 6TH AND 7TH.

ONE of the most satisfactory all-round Shows yet held by this successful Society was that opened on Tuesday last, and continued on Wednesday. The competition was keen, the exhibits of good quality for such an adverse season, the blooms much fresher than could have been anticipated, and all the classes well filled. The Hon. Secretary, Mr. G. Woodgate, has taken up the work of the Society in the right spirit, and he deserves much credit for the admirable results of his first year's service.

CUT BLOOMS.—The chief centre of interest was the class for forty-eight varieties, twenty-four incurved and twenty-four Japanese, in which the fifth 25-guinea challenge vase was offered for the first time this season. The honour fell to W. Furze, Esq., The Roselands, Teddington (gardener, Mr. E. Coombs), and the victory will be a popular one in the district, for Mr. Furze is widely known as an enthusiastic amateur who takes the deepest interest in Chrysanthemums specially and horticulture generally. The varieties shown by Mr. Coombs were as follows:—

Incurved.—Back row: Golden Emperor, Alfred Salter, Lord Wolseley, Lord Alcester, very handsome; Nil Desperandum, Queen of England, very deep; Prince Alfred, Empress of India. Middle row: Beauty, John Salter, capital; Prince of Wales, Mr. Bunn, Emily Dale, Jardin des Plantes, Mrs. Heale, Empress Eugénie. Front row: Sir Stafford Carey, Lady Hardinge, Mrs. Shipman, Princess Teck, Golden Eagle, Princess Beatrice, Mr. Brunles, Refulgence.

Japanese.—Back row: Boule d'Or, Madame C. Audiguier, Madame J. Pigny, M. Delaux, Soleil Levant, Duchess of Albany, Fair Maid of Guernsey, Edwin Molyneux. Middle row: Florence Percy, an excellent deep bloom; Criterion, M. Tarin, Avalanche, Val d'Andorre, very large and handsome; Madame J. Laing, Jeanne Delaux, and Madame B. Rendatler. Front row: M. J. Laing, Mdle. Lacroix, Mr. Garner, M. Baco, Mdle. Moulise, Madame Paul Dutour, C. Orchard, and M. Freeman, very fine. Both incurved and Japanese were highly creditable to the exhibitor, who well deserved the prize, though it has to be won again. Mr. J. Quarterman, gardener to C. E. Smith, Esq., Silvermere, Cobham, was second with rather flat, small, but fresh incurved blooms. The Japanese

were, however, of capital quality, Val d'Andorre, Criterion, J. Delaux, L'Adorable, and Soleil Levant being admirably represented. Mr. R. Cawte, gardener to J. P. Robinson, Esq., Brookleigh, Esher, was third with a clean collection, the incurved irregular, but the Japanese were of good substance, a fine corner bloom of Edwin Molyneux being notable. The fourth collection was disqualified as not distinct, Princess Imperial and Lord Alcester being shown in the incurved.

The class for twenty-four incurved varieties was well filled, and the quality of the blooms was satisfactory. Mr. C. Gibson, gardener to J. Wormald, Esq., Morden Park, Mitcham, won first honours with a clean collection, the back row fine examples of the Queen type, the others a little more irregular but mostly neat blooms. The varieties were:—Back row: Queen of England, Emily Dale, Alfred Salter, Empress of India, Golden Empress of India, Lord Wolseley, Lord Alcester, and Princess of Wales. Middle row: Prince Alfred, Mrs. W. Shipman, Sir Stafford Carey, Novelty, Nil Desperandum, White Venus, Lady Hardinge, and Jardin des Plantes. Front row: Mrs. Dixon, Venus, Mrs. Rundle, Refulgence, Mabel Ward, Golden Eagle, Mr. G. Glenny, and Princess Beatrice. Mr. E. Coombs was second with a bright, even, well arranged stand, a little wanting in substance. Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, was third, and Mr. W. Allen, gardener to Sir G. Russell, Bart., M.P., Swallowfield Park, Reading, was fourth amongst six competitors.

For twelve incurved varieties Mr. C. Slade, gardener to Lady Bowater, Richmond Park, was first, showing clean, even, medium size blooms of the following:—Back row: Empress of India, Queen of England, Golden Empress of India, Golden Queen. Middle row: Princess of Wales, Lord Alcester, Alfred Salter, Lord Wolseley. Front row: Jardin des Plantes, Prince Alfred, Mr. Bunn, and Jeanne d'Arc. Messrs. W. Reed, R. Cawte, and J. Snow were the other prizetakers amongst ten exhibitors. Mr. J. Reeves, Templemore, Oatlands Road, won the first prize for six incurved, showing Lord Alcester, Alfred Salter, Queen of England, Empress of India, Prince Alfred, and Jeanne d'Arc. Messrs. Skeet and Quarterman followed.

There were fourteen entries in the class for six incurved blooms, one variety; Mr. J. Daniel, Inglewood, Kew, leading with Empress of India, large and pure white. Mr. Coombs was second with similarly good Golden Empress of India; Mr. C. Beckett, gardener to T. H. Bryant, Esq., Juniper Hill, Dorking, following with Lord Wolseley, very fine deep blooms. In the class for six incurved blooms from amateurs who had not taken a prize in competition Mr. J. Reeves, Mr. Bradford, gardener to H. B. Wallis, Esq., St. Mary's Road, Wimbledon; and Mr. A. Felgate, Walton, were the prizetakers.

Japanese were well represented in the class for twenty-four blooms, distinct varieties, and there again Mr. C. Gibson won first honours. The varieties were as follows:—Back row: Edwin Molyneux, Madame C. Audiguier, Carew Underwood, Elaine, Criterion, Marguerite Marrouch, Fair Maid of Guernsey, and Hamlet. Middle row: Mrs. J. Wright, Yellow Dragon, La Triomphante, Mr. H. Wellams, Val d'Andorre, Peter the Great, M. Tarin, Sarah Owen. Front row: Mad. J. Laing, Mdle. Lacroix, Fernand Feral, Maiden's Blush, Avalanche, Mawet Postula, and M. J. M. Pigny. Mr. J. Munro, gardener to E. J. Paul, Esq., Cambridge House, Twickenham, was a very close second with a much more diversified and brighter stand, including grand blooms of Boule d'Or, J. Delaux, and Comtesse de Beauregarde. Mr. C. Beckett was third, and Mr. Sullivan fourth. There were eight competitors.

Mr. J. Snow was placed first for twelve Japanese varieties, showing Soleil Levant, Edwin Molyneux, Mrs. Cannell, Boule d'Or, Comtesse de Beauregarde, Lady T. Lawrence, Duchess of Albany, Mdle. Lacroix, Ralph Brocklebank, Mad. C. Audiguier, Mrs. J. Wright, and J. Delaux. Mr. J. Wilkin, gardener to J. Pearson, Esq., The Grange, Kingston Hill, was second, Mr. R. Cawte third, and Mr. H. C. Hoskings, gardener to Sir H. Thomson, Hurstside, West Moulsey, was fourth. Six exhibitors entered in this class. Messrs. J. Quarterman, W. Keet, and A. Felgate won the prizes for six Japanese in the order named.

For six Japanese, one variety, Mr. J. Snow, South Park Gardens, Wadhurst, Kent, was first with Edwin Molyneux. Mr. C. Beckett was second with Madame C. Audiguier; and Mr. E. Coombs third for Duchess of Albany, all fine representative blooms of their respective varieties. Sixteen stands were shown in this class. The class for six Japanese blooms from exhibitors who had not previously won a prize in open competition brought ten exhibits, Messrs. Bradford, Reeves, and Felgate winning the prizes in the order named.

Anemone varieties formed an interesting display. Mr. Sullivan was first with twelve blooms, showing Acquisition, Crispum, Nouvelle Alvéole, Emperor, Lady Margaret, Gluck, Louis Bonamy, George Sands, and Le Marguerite. Mr. E. Coombs was second, and Mr. J. Snow third. For twelve Japanese Anemones Mr. Sullivan was first, showing capital blooms of Jean Marty, Madame Cobral, Marguerite Solleville, Bacchus, Margouline, and Sœur Dorothee Souille. Mr. G. Woodgate, gardener to Lady Wolverton, Warren House, Kingston, was a good second, and Mr. W. Reed third.

Mr. R. Cawte was awarded the first prize for twelve reflexed blooms, showing King of Crimson, Amy Furze, Chevalier Damage, Cullingford, Dr. Sharpe, Mrs. Forsythe, and Phidias. Mr. C. Gibson was second, and Mr. E. Coombs was third. In several smaller and local classes the exhibits were also very satisfactory.

Mr. W. Allen was awarded the prize for the premier incurved bloom, Lord Alcester, a grand solid bloom 5 inches in diameter and 4½ inches deep. Mr. J. Munro gained a similar honour amongst the Japanese for a magnificent example of Boule d'Or 8 inches in diameter.

Certificates were awarded for the following new varieties.
Aralanche (Mr. E. Molyneux).—A beautiful white Japanese variety, referred to in our report of the Southampton Show.

Chrysanthemum Sunflower (Mr. E. Molyneux).—A golden Japanese, previously certificated by the Royal Horticultural Society and the National Chrysanthemum Society, from Mr. Holmes.

Chrysanthemum Alfred Lyne (Mr. J. Lyne, Belvedere Gardens, Wimbledon).—A sport from Novelty, somewhat in the way of Lady Hardinge. It originated in 1887, and has been carefully tested. The colour is distinct, a kind of pale purplish mauve with a silvery tip, and though most nearly approaching Lady Hardinge it was found, after careful comparison, to be distinct enough to merit recognition.

SPECIMEN PLANTS AND GROUPS.—The groups of Chrysanthemums were not quite so good as usual. In the first-prize group the blooms were decidedly heavy, but the foliage was thin. On the other hand, the specimen plants were in unexpectedly good condition. The blooms in the winning exhibits were not large, but the plants were well flowered.

The first class in this section was that for a group of miscellaneous plants arranged for effect on a space not exceeding 100 square feet. Three were in competition, and the premier award went to Mr. J. Bush, gardener to A. W. Aston, Esq., West Hill Lodge, Epsom. White Chrysanthemums were prominent amongst the flowering plants, Bouvardias lending colour, and blue, white, and red Primulas amongst Ferns in front formed an effective margin. Mr. T. A. Glover, gardener to E. Ellis, Esq., Manor House, Wallington, was second, *Oncidiums* being employed in his group with good effect. Mr. Pitcher, gardener to Mrs. Dunnage, Albury House, Surbiton, was third.

Collections of Chrysanthemum plants to occupy a space not exceeding 50 square feet were shown by five growers, the first going to Mr. Springthorpe, gardener to R. H. Alexander, Esq., Gifford House, Rochampton. Reference has already been made to this group. Mr. Pitcher's plants, which secured the second prize, were somewhat light in point of bloom. Mr. Stemp, Randalls Park Gardens, Leatherhead, showed a compact group, his dwarf front row plants being admirable little specimens, but the blooms throughout were small. Mr. Hunt, gardener to C. Boyles, Esq., Broghill, Wimbledon, was fourth.

Six trained specimens, incurved, with single stems, incurved. Two entries. Mr. Cawte was a very creditable first, good specimens of Prince of Wales, Mrs. Dixon, Mrs. G. Rundle, Mr. G. Glenny, Baron Beust, and Empress Eugénie gaining him a ready victory. His solitary opponent, Mr. Reid, showed Prince of Wales, Mrs. Cobray, and Mrs. Dixon in fairly good condition. There was only one exhibitor in Class 4, that for four reflexed varieties—namely, Mr. Reed, and the first prize was awarded to him. Peter the Great and Pink Christine were his best plants. There were three competitors with three standards, distinct varieties, Mr. Cawte winning with Madame B. Rendatler, Mrs. G. Rundle, and Prince Alfred. Mr. Skeet was second, and Mr. Elliott, gardener to Mrs. Harrison, Leydon House, Mortlake, third. The latter had the largest plants, but they were lightly bloomed. Trained Japanese were shown by Messrs. Fullick, Woodlands, Collins Road, Merton; and W. Reed only, the former winning.

Pompons were admirably shown, Mr. Cawte being unopposed with six plants, and he was awarded the first prize, the varieties best shown being Marie Stuart, Rosinante, both admirable specimens, and Mr. Astie, Marguerite de Coi was not out. Mr. Reed also had an easy victory with three plants, showing well, and the prizes for single plants went to Messrs. Elliott, Cawte, and Reed.

In minor classes for plants the principal prizewinners were Messrs. R. Press, J. Pay, W. Holt, J. Lemon, and J. Bowden.

PLANTS FOR TABLE.—There were eleven exhibitors of nine plants for table decoration, and these, arranged in the centres of the tables, gave a pleasant relief to the hlooms. Mr. Sullivan was first with *Dracaena superba*; Crotons Countess, Prince of Wales, Lanei, and superbum; *Aralia elegantissima*, and *Cocos Weddelliana*. Mr. Carter, gardener to Alderman Evans, Ewell Grove, second; and Mr. Waite, gardener to Col. Hon. W. P. Talbot, Esher, third. Mr. Burton, gardener to Capt. Fenwicks, Wimbledon, won with six plants, Mr. Cawte following. Six berried plants in pots brought two competitors, Mr. W. Reed showing very effective plants of red and yellow Capsicums for first prize, Mr. Elliott following with *Solanum Capsicastrum*. Messrs. Carter, Glover, and Pitcher were successful with Primulas.

STANDS OF FLOWERS, BOUQUETS, &c.—Special prizes were given for these, those offered by Mrs. Shrubsole going to the following:—Mrs. Drewett, Russell Villa, Richmond Road, Kingston, was first for a remarkably beautiful stand, in which scarlet Bouvardias, *Lapageria alba*, and *Eucharis grandiflora* played a prominent part. It was most lightly and tastefully arranged. Miss K. Prior, Hesse House, Kingston, was second, her stand being a little too packed, and Miss Scrivener, Boston Lines, third; a promising stand, this being her first attempt. Mrs. Mackenon's prizes for stands of hardy shrubs, Ferns, and Grasses grown out of doors went to Mrs. Gardener, Strawberry Hill, and Mrs. Benson, Elm Road, Kingston.

Buttonhole bouquets were charming, the prizewinners being Messrs. Loft, first; Perkins & Sons, Coventry, second; Brown, Richmond, third; Miss A. Drewitt, fourth; and Mrs. Drewett, fifth. Mr. Loft's victory over two such formidable opponents as Messrs. Perkins and Brown was most creditable to him. Hand bouquets were most beautiful too. Messrs. Perkins & Sons were first with an example of their usual skilful arrangement, the second prize bouquet being shown by Mr. Brown of Richmond. Mr. Miller, florist, Surbiton, was third.

FRUIT.—Grapes were well shown, sixteen competitors showing three bunches of black Grapes. Mr. C. Griffin, gardener to Miss Christy, Coombe Bank, Kingston, was first with well-coloured examples of Alicante; Mr. F. Batten, gardener to R. Venables, Esq., Hollywood, Wimbledon, was second with Gros Maroc; and Mr. J. Bowerman, gardener to C. Hoare, Esq., Hackwood Park, Basingstoke, was third for Alicante. Eight stands of three bunches of white Grapes were entered. Mr. C. Griffin won first honours for excellent samples of Muscat of Alexandria; Mr. J. Bowerman was second with clean, well-coloured bunches of the same variety; Mr. H. Loft, gardener to J. F. Schwann, Esq., Oakfield, Wimbledon, being third for the same not so well coloured.

Mr. W. Bates, Poulett Lodge Gardens, Twickenham, was first for four dishes of Apples, fine samples of Warner's King, Peasgood's Nonesuch, Cox's Orange Pippin, and Dumelow's Seedling. The best Pears were shown by Messrs. T. A. Glover, W. Reed, and H. W. Pitcher.

NATIONAL CHRYSANTHEMUM SOCIETY.—NOVEMBER 7TH AND 8TH.

As had been expected, the annual Exhibition of this Society in the Royal Aquarium, Westminster, proved a most successful gathering of exhibitors and exhibits, and we regret that we are unable to give a full report owing to the brief time at our disposal before going to press. A carefully prepared and liberal schedule had been published, the substantial prizes offered in the more important classes attracting numerous competitors, and the several features of special interest provided this year induced a large number of visitors to attend. All the arrangements were admirably carried out under the superintendence of the Hon. Secretary, Mr. William Holmes, and the Society may be congratulated in having secured another decided success.

CUT BLOOMS.—The leading class in this section was the novel one provided for horticultural and Chrysanthemum societies, in which a collection of forty-eight blooms, twenty-four incurved, not less than eighteen varieties, and twenty-four Japanese, distinct. The prize offered consisting of a challenge trophy and £10, the cash to be handed to the treasurer of the society winning the award, to be equally apportioned to the growers of the blooms staged, and the challenge trophy to the president, to be retained by him for twelve months, and returned to the Secretary of the National Chrysanthemum Society not less than fourteen days before the November show of 1889. The title of the winning society to be engraved each year on the trophy. There were five entries in this class, and the Weald of Kent Gardeners' Mutual Improvement Society, represented by Mr. J. Doughty, The Gardens, Angley Park, Cranbrook, was successful in winning the honour for the first time. Both the Japanese and incurved were good and wonderfully fresh. The Southgate, Wimbledon, Bristol, and Highgate Societies also showed well, and but for the incurved having suffered in transit the Wimbledon Society would have stood a good chance of success.

Cut blooms generally were of good quality, and some were exceptionally so, the Japanese perhaps being the finest throughout the Show. All sections were, however, well represented, including the Japanese, reflexed, Anemones, and Pompons. The best forty-eight incurved blooms were shown by Mr. J. Doughty, who was awarded the first prize for really grand blooms, the breadth of the florets being remarkable. The double success of winning the Society's challenge trophy and taking first with forty-eight such fine blooms as these deservedly placed Mr. Doughty as the champion of the Show. Mr. J. Horsefield, Heytesbury, was second, also showing fine blooms.

For forty-eight Japanese, Mr. J. McKenzie, gardener to T. S. W. Cornwallis, Esq., Linton Park, Maidstone, won the premier prize with excellent blooms.

Specimen plants are not quite so well represented generally, but the groups are effective, especially those in a space equal to 100 square feet. In that class Messrs. N. Davis and Jones, Camberwell, succeeded in winning the gold medal for a bright arrangement, including a due proportion of incurved and Japanese.

Six stands of Chrysanthemum flowers and foliage were staged, Mr. J. Chard, Stoke Newington, winning first honours for a most tasteful arrangement; Mr. W. Brown of Richmond taking the second place, also with a very effective stand. Some divergence of opinion existed respecting the exhibits in this class, but they were judged on their merits as regards tastefulness in arrangement.

Fruit and vegetables are shown extensively, the galleries and St. Stephen's Hall being filled with competing and non-competing exhibits, Apples, Pears, Potatoes, and collections of vegetables being well represented. Horticultural sundries, implements, and buildings also occupy much space.

At 2 P.M. on Wednesday the Show was formally opened by Sir Guyer Hunter, M.P., who said he was pleased to learn that this, the forty-third annual exhibition held by the Society, is both the largest and the best yet obtained. There are 504 exhibitors from all parts of the country, and the entries in the classes are very numerous. The President, Mr. E. Sanderson, made a few appropriate remarks, and Mr. W. Holmes, in proposing a vote of thanks to Sir Guyer Hunter for attending to open the Exhibition, observed that it was the first time in the history of the Society that this little ceremony had been performed, but he thought it was one they might continue with advantage. The vote of thanks was carried by acclamation. Judges and visitors shortly afterwards assembled at luncheon, where several speeches were made by the officials and friends of the Society.

THE NATIONAL AURICULA AND THE NATIONAL CARNATION AND PICOTEE SOCIETIES.

(SOUTHERN SECTIONS.)

THE annual general meetings of the above Societies were held on October 23rd, and not only were inaccurate reports of them sent to the gardening papers, but articles were written founded upon the erroneous paragraphs. As Honorary Secretary of both Societies, I beg to say that not a line was either written or prompted by me of those matters. The first of the inaccuracies I complain of is the statement that it had been decided to hold the annual displays at the Crystal Palace. Nothing of the kind was decided at the meetings. The Societies are also termed "National Societies," but to be correct the meetings were of the "Southern Sections" only. As some of the criticisms have been adverse it is only fair to the north to say that they are not included. I decidedly object to the publication of the proceedings of any societies such as have appeared in the papers, even if they had been accurate. It was decided at the meeting this year, as it was also last year, to communicate with the Directors of the Crystal Palace to ascertain on what terms they would receive the Societies; at the same time it was agreed that a similar application be made to the Council of the Royal Horticultural Society. I thought it best while negotiations were in progress to make no public statement; others evidently differed from me in this respect. When it had been finally decided where the Exhibitions were to be held I would have sent the usual report to the Press.—JAS. DOUGLAS, *Barking Side, Ilford.*

FRUIT FORCING.

PEACHES AND NECTARINES.—*Early-forced House.*—The final thinning of the shoots in the earliest house should have immediate attention. Wash the trees in the first instance with warm soapy water, and afterwards dress them with an insecticide. Thoroughly cleanse the glass with water, the woodwork and trellis with soap and water, and whitewash the walls. Tie in the trees loosely, allowing space for the growth to swell without binding, letting the young shoots be laid in so as to secure an even spread of foliage, and sufficiently wide apart to admit of next year's growth being trained without crowding as the fruit approaches maturity; and to effect this the shoots should be 9 to 12 inches apart, and not closer on the main branches than 18 inches. A shoot of 12 to 18 inches in length will give a heavy percentage of fruit for thinning, provided the wood be well ripened, and a Peach worthy of the name to every foot of trellis covered by the trees is quite as much as trees under early forcing can support year after year. If the lights have been removed they may be kept off until the middle of the month if the weather be mild, or if put on ventilation should be freely given until the house is closed. If the roof lights are fixed the doors and ventilators may be constantly open, and see that the inside borders of such houses do not lack moisture, but give a thorough soaking of water if necessary, so as to moisten the soil down to the drainage.

Trees Intended to Ripen their Fruit in June.—Trees that are to be started at the beginning of January will now be leafless, and should be pruned without delay, while, if the wood on which the fruits were borne this season was cut out when the fruits were gathered, this will be light. Indeed beyond removing any weak growths and where they are too crowded the knife will not be needed, for however long the shoots, they will, if the trees are healthful, be ripened to their points, having stout short-jointed wood well set with flower buds. Trees extending may have the leading shoots cut back to originate others for furnishing the trees, being careful in all shortening the shoots of the current year to cut back to a wood bud, or if to a triple bud, making sure that the centre is a wood bud, as trees in some cases form triple fruit buds at a joint. The house and trees should be thoroughly cleansed and secured to the trellis. The roof lights having been removed some time ago need not be replaced until the middle of December, as the autumnal rains will thoroughly moisten the borders and keep the trees in a complete state of rest, which is a matter of importance, as trees that ripen their fruit and growths early are easily excited, and excitement in November by putting on the lights, should the weather prove mild followed by a check, is very often the cause of the flower buds falling when they should be expanding.

Houses Started in February.—These trees are now parting with their foliage, and should have all the air possible. Any lifting or root-pruning yet in arrears should be seen to and brought to a close as soon as possible. When the leaves are all down it will be an advantage to remove the roof lights and expose the trees for a month or six weeks, but if the roof lights are not moveable admit air freely in all but severe weather, and see that there is not any deficiency of moisture in the borders. If the trees are not lifted remove the surface soil down to the roots, and supply fresh stiff loam to which has been added some charred refuse and steamed bonemeal.

Late Houses.—Lifting and root-pruning trees in these structures

should be taken in hand at once and completed without further delay. During the operation the house must be kept rather close, the trees syringed, and the roots as little exposed as possible. When the roots have taken to the fresh material ventilate freely. If the trees do not require lifting it will be well to keep the house rather close by day, especially from sun heat, and to throw it open at night, which will soon ripen the growths, especially if the wood be thin, so as to allow of light and air having free access to the wood. If the wood be at all crowded it should be well thinned. There must not be any deficiency of moisture at the roots or they will not develop the buds perfectly, falling when they should be expanding in spring.

CUCUMBERS.—Plants which have been in bearing the past three or four months will be considerably renovated by receiving a good surface-dressing of a mixture of three parts light turfy loam, and one part in equal proportions of peat and charcoal. The loose surface soil should be first removed, and the surface dressing applied warm. When the roots are working freely in the fresh material surface-dress or mulch with horse droppings, a sprinkling once or twice a week, the manurial properties of which will be worked down by each successive watering, imparting vigour to the plants, and giving the fruit a deep colour with a "blue" lustre. Examine the soil, and when water is necessary give a thorough soaking at the same temperature as the house. Ventilate freely during mild weather, which must not be done to lower the temperature, but to prevent it becoming too high, increasing it as the temperature rises, so as to prevent chilling draughts, which are highly injurious to the plants. Maintain a night temperature of 65°, but on cold nights 60° is sufficient, with 70° to 75° by day with fire heat, advancing 10° to 15° from sun heat. Close early in the afternoon, and the glass being clean a good heat will be secured, which must be accompanied by a fair amount of atmospheric moisture. Canker is unusually scarce this autumn, but if it appear rub quicklime well into the infected parts. Aphides should be combated by moderate, frequent fumigation.

Winter Fruiting.—Add more soil to the hillocks or ridges of late plantings as soon as the roots show through the sides, and complete the earthing of the first autumn plants, and then place a mulching of short sweetened stable manure, which will act beneficially by keeping the roots in an equable condition as to moisture, encourage surface roots, but stimulate them by the manurial properties being washed down. Decomposing material is also of benefit to the foliage through the ammonia evolved. Keep the bottom heat steady at 80°. Use as little fire heat as possible. On fine mornings turn off the heat about eight o'clock, or by the time the solar heat is acting on the house, and keep up the required temperature without having to resort to much ventilation to keep it from rising too high, as would be the case when the fires are kept going until the maximum day temperature is reached. The heat should be turned on again when the sun is going off the house, so that by the time the heat subsided by early closing has fallen to 75° the heat radiated by the pipes will be sufficient to maintain the temperature through the night at 65°, to effect which, in severe weather there should be plenty of pipes. Blinds of such material as frigidom will prevent the necessity of so much fire heat, and are particularly useful during falls of cold rain or snow. They must be used so as to interfere with as little light as possible.

PLANT HOUSES.

Passifloras and Tacsonias.—Where these are trained under the roof of plant structures they must be subjected to a liberal thinning. This can be done now without the least injury to the plants, and with beneficial results to the occupants that have to be grown beneath them. It is essential that every ray of light and sunshine should be admitted to the plants beneath. Tacsonia Van Volxemi will still produce flowers; these should be allowed to hang naturally from the roof, and as shoots cease flowering cut them close back. The flowers are very useful where low floral decorations are required on the dinner table. Plenty of wood can be removed without the destruction of many flowering shoots, so as to admit light freely to the plants below.

Imantophyllums.—These plants will have completed their growth, and those not wanted to flower for some months should have a cool airy structure. They should also be watered with great care, giving considerably less than has been the case up to the present time. If overwatered during the resting period the tips of their dark green foliage are certain to turn yellow, and the beautiful appearance of the plants is destroyed. If kept on the dry side they will remain in perfectly good condition. Some of the earliest plants are showing their flowers, and will be much brighter in colour if they are developed in a little warmth. At this season of the year the flowers, if allowed to expand in a cool house, are practically colourless. Seedlings raised from good varieties will be better in a cool than in a heated house during the season of rest. This treatment results in increased strength and vigour another year.

Dielytra spectabilis.—Imported roots of this easily forced plant can now be obtained, and may be potted in good soil in 5 and 6-inch pots. Home-grown roots are as good as those that are imported from the Continent annually, provided they have been prepared for the purpose. When the stock is grown at home the finest crowns only should be selected, and the smallest replanted for the following year's supply.

Acacia Ricana.—Where this plant is grown up pillars or under the rafters of the roof do not attempt to tie the shoots up in a formal manner. By doing this its beauty is totally destroyed. The long slender shoots should be permitted to hang naturally from the plant, the plant has then a graceful appearance when in flower. If it obstructs

too much light from below, thin the shoots so as not to destroy the natural appearance of the plant.

Clematis indivisa.—Regulate and thin the shoots of this and its variety *lobata*. Do not remove more shoots than is absolutely necessary, for this plant is better liberally pruned back after flowering, if any reduction of the plant is required. This looks better than many climbers when trained under the roof of houses in a formal manner. Its flowers being light remove the stiff appearance it would otherwise possess. It is, however, most picturesque when numbers of shoots are allowed to hang from the main stem trained under the roof. Watch for aphides, which are very liable to attack this plant. Fumigating the house with tobacco smoke is the best means of eradicating them.

*Bignonia*s.—When once these plants are thoroughly established and have abundance of root they make shoots of an enormous length in a season. Plants of this description will bear severe thinning. Unless they are liberally cut back they soon become crowded, and if they are not exposed to full sunshine they will fail to flower satisfactorily.

Lonicera sempervirens.—This plant usually begins to look shabby from the present time by the ripening of its old foliage. Although it will continue growing and flowering throughout the winter in most houses where the temperature is kept at 45° to 50°, it is best to prune it hard back now. By so doing the shoots break into growth again and flower freely early in the spring.

Habrothamnus elegans.—At this season remove the puny shoots that are too weak for flowering. This plant is best against a tall pillar where it can be pruned close back after flowering and then be allowed to grow naturally without either tying or stopping the shoots. The shoots can be thinned at the end of June or July if they are likely to overcrowd the plant. This plant is subject to attacks of green fly, and it must be destroyed the same as advised above. Few flowers are more useful than these for the methods of table decoration that are now so generally carried out.

Rhynchospermum jasminoides.—This and *Lapagerias* need very little attention in thinning; the main object is to regulate the shoots of the former ready for the time it will come into flower, and the latter after they have done flowering ready for growth the following season. Both are liable to the attacks of mealy bug. Clean them thoroughly and fumigate with tobacco, or syringe with a solution of tobacco water if any trace of thrips can be found upon them.

Plumbago rosea.—*P. rosea* and its variety *coccinea* may be brought into flower if the plants are wanted, and placed in a temperature of 60°. Watch for thrips, which soon attack and destroy the foliage. *Linum trigynum* may also be pushed forward. The earliest *Poinsettias* will develop better bracts in a temperature of 60° to 65° than in a lower temperature. They can be gradually hardened afterwards for cooler houses.

Justicia flaricoma.—A few of the earliest of these may be pushed forward in a temperature of 65° to bring them into flower. By this treatment the heads may be reduced in size, but they will be found very useful, and nothing is lost in the end. The plants will flower again if well cared for after they have flowered the first time. The plumes the second time will be of large size. It is a mistake to throw them away after they flower the first time, for the plants are always more effective the second season, and there is no difficulty in having them in flower over a period of six months.

THE BEE-KEEPER.

FEEDING BEES.

ITS USES AND ABUSES.

At page 391 I drew the attention of bee-keepers to one evil arising from rapid feeding in autumn, and the following remarks will more fully explain the subject.

Feeding at all times is a necessary evil, and ought only to be resorted to when it cannot be avoided. In addition to creating damp inside the hive, rapid feeding sometimes ends in the total destruction of the stock by robber bees. The bees being often fully gorged cannot defend themselves against robbers, and so fall an easy prey to them, the contents of the hive being quickly carried away. In previous articles I warned bee-keepers against another danger arising from late feeding—viz., setting breeding a-going, which at this season with queens that have done considerable egg-laying (although young), there is a likelihood of some of them being deposed, the bees raising royal cells through the inactivity of the queen. Already many cases of the kind have been brought under my notice, and many queenless hives or drone-laying queens may be expected next spring.

One hive I was asked to see had already thrown out one young queen, which the owner attributed to the wisdom of the bees

throwing out the young one and retaining the old one. "Do not be so fast," I exclaimed, "will you allow me to examine?" The request was granted. An inspection betrayed two royal cells vacated, and a young queen and the old one on the same comb. No jealousy seemed to exist between them, but I could easily see that no attention was being paid to the old one, while she was occasionally being nipped at by some of the bees. I immediately removed the young one; yet, notwithstanding the old queen was still present, a partial commotion took place amongst the bees, showing plainly that the laying queen was doomed, and the greatest wisdom was displayed in removing the young one.

Even though queens may not be deposed at this season through late and untimely breeding, there is a risk in the queen so encouraged giving way in spring through autumn feeding. When bees require feeding in the autumn the proper time to do it is immediately the honey harvest is over and when there is still a considerable amount of brood in the hive, so that the queen will not have the chance of depositing many eggs; then both she and the bees will be allowed to go on in their normal state and prepare for the winter. With their natural rest they will commence work at the proper time and continue it until the change in the season. The so-called stimulative feeding has as bad or greater evils than rapid feeding. It causes a dwindling away of bees during the time of its continuance, an increase of egg-laying by the queen, with an equal diminution of the eggs by the bees eating them on a sudden decrease of temperature, while robber bees are ever on the wing when or wherever it is going on.

In addition to feeding immediately after the honey season is closed (which should serve the bees till next honey season) bees can be fed when newly swarmed and when they have been deprived of surplus honey with an extended harvest in view. If bees are not fed after being deprived of surplus honey they are liable to eat out their eggs and brood, even although much honey is left in their hive. Very little feeding at this time will not only prevent it, but will encourage the bees to continue bringing forth young ones, which will place the hive in a state capable of gathering much honey from the expected late bloom, which may be the Heather. These are the only times feeding should be resorted to. In a well managed apiary feeding at other times is never thought of, neither is rapid feeding, such as giving from 14 to 20 lbs. at a time, advisable. From 2 to 4 lbs. daily, or rather nightly, at the proper time is a good and safe medium. Nuclei have to be nursed or supplied with frames of comb containing honey.

What is the best feeder? is asked by several correspondents. My answer is, The frame feeder; not the one used as a dummy, but having the top bar of the frame about three-eighths of an inch thicker than usual, and having a trough cut along its centre to within an inch or so of its end piece. The top edges of the bar are reduced until a beeway is formed, a space in the centre is bridged off, and a thin cover flush with the adjoining frames completes it; a tin having a spout to suit, and fitted with a lead valve completes the feeder. This tin may be as large as the bee-keeper desires, or so small as to hold half a pound only.

The advantages of this feeder are—the syrup is placed near the tongues of the bees, which they take more readily than from any feeder that has the syrup placed at some distance, as is the case with most. Nuclei and weak hives can be fed with these feeders when they would die rather than take it from most other kinds, and this property is the one we determine what is the best feeder. A strong hive will take syrup from any sort of feeder, but weak hives will not. Moreover, although this feeder is suitable for a weak hive, never exposing much syrup at a time, it is also a rapid feeder where there are bees to take it.

The foregoing does not exhaust the subject. "A Renfrewshire Bee-keeper" many years ago in the *Cottage Gardener* described the mode and advantage of filling combs with syrup and placing these inside the hive. The Americans caught hold of it, and again those on this side the Atlantic have adopted the system as a new

thing. The same writer also described the mode of manipulating bees. The able way he did so, and the humane results, were very superior to anything we have either seen described in writing or practised at our leading shows, where the appearance of the ground after manipulation betrayed thousands of dead bees, though not one should have been seen had the proper care been taken and the proper lesson given. This is a second query by an Argyshire bee-keeper, "A. M. M." The question is, "How best to manipulate bees?" There are in all manipulations two things to be observed—viz., neither to kill nor irritate bees. Be careful that no offensive smell irritate them. Approach the hive cautiously, about 3 o'clock P.M. is the best time to manipulate. Bees returning from the field do not sting, only those that are flying and left their hive on being disturbed; a slight puff of smoke at the entrance, or a little carbolic acid upon the alighting board, will tend to soothe the bees. Smoke causes the bees to fill themselves, and no full bee stings. When the bees are quieted by either of these means the doorway may be closed for about thirty seconds or so. The bees will, during this interval, be attempting to gorge themselves with honey. Now uncover the hive, by degrees smearing the tops of the bars with carbolic acid, always in such a way as the bees will not be injured by coming into contact with it. If properly done it keeps the bees effectually down. Whenever they make the retreat before the acid they are subdued, and the frames may be manipulated forthwith. If the hive is a straw one the precautions are all that is necessary, when after a short time it may be inverted for further procedure. Caution is necessary, however. Never leave a hive in the middle of any manipulation, or woe betide the party who approaches it after with the view of finishing it off. A little forethought and patience on the part of the beginner will soon make him master of the art of manipulating bees. Other queries will be answered in future issues.—A LANARKSHIRE BEE-KEEPER.

THE NEW GLASS SECTION.

In my letter describing the above, on page 413, I omitted saying how it was put together, and as the Editor, in his foot-note, says "the glass being made secure in position by fine wire" may lead many to suppose that all the pieces of glass forming the section are held together by wire, I think I cannot do better than describe it somewhat in detail.

The sides of the section are of one width all round; the top piece of glass is split, to grasp a piece of foundation between, but this plan of fixing it will not be used or recommended by me, and was only done this year as an experiment. There are no corner joints to it; nothing, in fact, but the four glass sides and the honeycomb within can possibly be seen.

The sides of the section sent are only protected, after being finished by the bees by two squares of glass cut the exact size of the outside measurements of the section, which are fastened on with "fine wire" tinned; this glazing the sides is what is usually done to protect the comb from dust or insects, &c.

The advantages to be gained by the sections being of one width all round are many, one being they can be crated for market in a skeleton crate formed of very little more than a bottom board placed edge to edge, with a piece of glass at the outer sides, when it will at once form a massive lump of tempting honeycomb, insect-proof and practically dust-proof. When thus crated the faces of the comb in each section will be a bee space apart, but as a vivid illustration of how bees economise every little bit of space, and of how much they prefer glass, they have carried up their comb to the edge of the glass sides, storing honey in the cells next to it; thus the honeycomb looks $\frac{1}{2}$ of an inch thicker than it really is. This extra thickness is marked up with a "slope," and cannot be seen except by closely inspecting the section. This important advantage, which makes the section look bigger than it really is, makes a crate look a solid mass of honeycomb and adds strength and security in travelling, was not anticipated by me, and is wholly because bees prefer glass to wood within which to store their honey.

The section after being "glassed," was wrapped up in paper and enclosed in a small box surrounded with cork dust and sent by post, and the fact that it reached the Editor's hands safely should be conclusive proof that it is not really a "fancy" article, but one that is full of the elements of utility.

When they are "on the market," I think there will be few shop-keepers who will not take a pride in having half a dozen or so always on their counter or in the window, just protected at the sides with two pieces of glass.—A HALLAMSHIRE BEE-KEEPER.

[The section referred to was handed to Mr. Neighbour, the eminent apiarian, and can, we assume, be seen at his establishment, 149, Regent Street, London.]

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Tomatoes at Chiswick (A Scotchman).—The Tomato house illustrated on page 361 is 100 feet long and 30 feet wide. The prices (wholesale) realised up to that time, were 7d. and 8d. per lb. for the best, 5d. and 6d. for the seconds. The price obtained now is 9d. per lb. The distance between the plants is 2 feet 4 inches, and they have not been topped nor laterals permitted to grow, but the fruit is borne on the main stems. Thanks for your note, which will be remembered.

Zephyranthes (J. E., Aberystwith).—The bulbs at this time of year require resting, keeping the soil dry if they are in pots, or if out of doors they might be lifted and placed in sand if the soil and situation are at all damp. Both *Z. Atamaseo* and *Z. cernata*, which you mention, are hardly in the south of England and in other moderately warm districts, but they have such a beautiful appearance in pots that they are well worth growing in this way for the greenhouse or any cool structure. They prefer a somewhat sandy well drained soil, but require plenty of water when growing and flowering.

Ichneumon Fly (B. J.).—The specimen sent is a four-winged fly of the ichneumon tribe, the particular species being *Ichneumon crassorius*. They are insects of parasitic habit while in the larval or preparatory state; the eggs are laid by the parents upon the bodies of other insects, or in some instances deposited in their nests, and the young larvae burrow into and feed upon these, of course to their destruction. Many of the ichneumon flies attack caterpillars, hence they are really serviceable to the gardener. In the perfect state they are frequently seen upon flowers, to which they are attracted by the honey. Should one of them be taken in the hand, provided it is a female, the fly generally uses the ovipositor or egg-layer as a kind of weapon, and drives the sharp end into the skin; this act, however, is not accompanied by the emission of a poisonous liquid as is the case with the gnat and certain other species.

African Groundsel (T. R.).—This name has been given to a somewhat remarkable climbing or trailing plant—*Senecio macroglossa*, which is figured on page 67, vol. viii., January 24th, 1884. It is described there as having leaves like Ivy and flowers resembling those of the *Etoile d'Or* variety of *Chrysanthemum frutescens*. *Senecio macroglossus* has been found on the Table Mountain, at the Cape of Good Hope, and in other districts of South Africa, seeds having been first sent to Kew by Mr. Sanderson in 1868, and from these probably the first plants grown in this country were raised. Sir Joseph Hooker states that he has heard that in some continental or other cities this plant is grown in rooms and trained round the walls near the ceiling, and from its peculiar succulent structure it would, no doubt, be fitted for such dry positions, though its strength would be severely tested in ordinary English rooms. The best position for it is a greenhouse or cool stove, but the former is preferable, as it cannot endure a moist atmosphere. It is not particular as to compost, light sandy loam with a little leaf soil or old decayed manure being suitable, and if grown in a pot this must be thoroughly drained and water very carefully supplied. The best plan is, however, that adopted at Kew, where it is planted out and trained up the roof of the house.

Grapes not Keeping (A. B.).—No doubt the cold sunless summer has had "something to do with" the tendency of the Grapes to decay sooner than usual this year. In the first place many were later in ripening than usual, and where, as in your case, the wood is still immature the fruit cannot be completely ripe. The rain falling in your district "every day for a week" has also been against good keeping, and extra care is essential under the circumstances to maintain a dry buoyant atmosphere. The "same treatment as formerly" is not always the best treatment when the essential conditions differ. You would have acted wisely in having employed more fire heat some time ago than you appear to have done, and we gather from your letter you only "keep a little fire heat on in the daytime" even now. If that is so the Grapes, considering the state of the Vines, are almost certain to decay prematurely, for the berries must have been so cold on many nights as to cause a deposition of moisture on them by condensation, almost inevitably to be

followed by mould. The pipes should never be cold, but a temperature of 45° at night, or even more, maintained with a dry atmosphere, ventilating judiciously on favourable occasions. The greater the disparity between the night and day temperatures and the more sudden the fall of temperature and the longer it remains at a low figure, the greater the liability of your Grapes to decay.

The Purple-leaved Birch (*W. N., Yorks.*).—It was raised in America, and its discovery was described by M. Ed. André in *L'Illustration Horticole*. "On the 5th of June, 1872," writes M. André, "whilst going through the horticultural exhibition at Orleans as one of the party of judges, the attention of myself and of my companions was drawn to a number of shrubs consisting of forty plants all of one species, which were almost hidden in the recess of a somewhat darksome corner. It required but a moment's contemplation to enable us to grasp the full importance of the remarkable plant, which was, without doubt, the chief object of interest in the exhibition. It was a very beautiful variety of the common white Birch (*Betula alba*), but the leaves were completely purple or purple-black, like those specimens of the Beech so often seen in our parks. Here was indeed a real discovery, and a golden medal was with one accord awarded to it. It was obtained by chance by an old hand of the firm of Transon Brothers, named Dubois, from a sowing of the ordinary Birch. He very soon observed the unaccustomed appearance of the plant, and after having raised it he took grafts therefrom, and placed them on young stocks of the common variety, and afterwards established them in pots. It will be a great acquisition for our parks, and may be most advantageously associated with the Purple Beeches, the habit of which is quite different. It succeeds in the poorest soils, at the same time preserving all the strength and rural beauty of the original type."

Culture of Epidendrum bicornutum (*B. C.*).—The Epidendrum is rather difficult to cultivate, but the following notes by an experienced Orchid grower who has been very successful with it will explain the treatment required:—"The best way to grow it is in baskets suspended from the roof, or on pieces of Tree Fern stem. I have grown and flowered it under both systems, and if grown in baskets a compost of very fibry peat, moss, and charcoal should be employed. The plant roots freely in its natural habitat, but is rather shy-rooting under cultivation. The plant is a native of the West Indian Islands, particularly Trinidad, consequently it requires the temperature of the East Indian house. Having a friend living in Trinidad, I wrote him for particulars with regard to where it was found and under what conditions, and I will give his reply as I received it. He writes, 'With regard to your questions respecting *E. bicornutum*, if I tell you how I collected it no doubt that will suffice. I went out one day last week, hired a boat to carry me to the Five Islands, a group of irregular size, standing at no great height out of the water, in one bend or basin of our harbour, which may be called rocks left after the severance of that part from the mainland by the encroaching influence of the sea. Round these islands one can sail and soon load his boat by pulling the tufts off the ledges of the rocks or any cavity. It is subject to drenchings of water by the action of the waves, is generally fully exposed to the sun, and as it is surrounded by water the plant must be subject to heavy dews owing to the great variation in temperature of the land at night. I soon collected a load, though I am afraid they are too much advanced in growth for travelling.' By these remarks it is easily perceived that the three most essential requirements of *E. bicornutum* are heat, exposure to sun, moisture, and a moderate low night temperature, and if these be carefully attended to it should make satisfactory progress. Any trouble bestowed on it will, I am convinced, well repay the cultivator."

The Rationale of Planting and Potting Bulbs (*M. R. S.*).—You ask for "information on the rationale of bulb-planting in the open border and in pots," and observe that "neither Lindley's 'Theory and Practice of Horticulture' nor Thompson's 'Gardener's Assistant' throw much light on the matter, especially as to the depth at which bulbs should be planted to secure complete success." Something more than the mere depth that bulbs are covered is requisite for achieving complete success; still, we will endeavour to answer your question. The bulbs of the splendid Hyacinths that are awarded honours at the London shows are scarcely covered, but the apex of such is about level with the rim of the pot, and the surface of the soil is made level fully half an inch below it. The same remark applies to Narcissi, Tulips, Crocuses, Scillas, and small bulbs generally are just covered with soil when grown in pots, and the pots in turn covered about 5 inches deep with cocoat-nut fibre refuse. This applies to all bulbs. In planting bulbs in beds for one season only—that is, removing the bulbs after flowering—they are covered a little more than their own depth with soil. Crocuses, for instance, are covered a little more than an inch deep, and Hyacinths twice that depth, about an inch thick of fibre refuse or leaf mould being spread on the beds after the soil is levelled over the bulbs. In planting bulbs in borders to remain permanently they should be covered from twice to thrice their own depth or thickness—Crocuses and the like 2 to 3 inches, Hyacinths and the like 4 to 5 inches. If planted near the surface the earth is washed from them sooner or later. But it is bad practice to simply press a dibber into the ground to those depths and drop the bulbs into the holes thus made, as they are then either suspended or rest on a hard base, and in adhesive soil these holes are really miniature wells in which water collects. The base on which bulbs rest should be light and free—roots then penetrate it readily and superfluous water passes away. Bulbs should also be covered with soil through which the growth can

extend freely, and the lighter it is the deeper they may be covered—for instance, they will push through 6 inches of leaf soil or gritty vegetable matter with greater freedom than through 2 inches of clay. It is an excellent practice to embed bulbs in and surround them with sand, or a mixture of sand and wood ashes, and too much importance cannot be attached to early planting. The more the crowns extend from bulbs out of the ground the worse it is for them, and root-extension should be slightly in advance of top growth for securing "complete success."

Names of Fruits (*J. Truro*).—1, Rotten; 2, Autumn Bergamot; 3 and 6, Bûre Hardy; 4, Catillac; 5, Red Doyenné. (*R. G.*).—1, Fondante Charnet; 2, Marie Louise; 4, Josephine de Malines; 5, Urbaniste; 6, General Todtleben. (*J. A. W.*).—The Apple is not King of the Pippins but Kerry Pippin. (*J. D.*).—1, Duchess's Favourite; 2, Rotten; 3, Scarlet Russet; 4, Fondante d'Antenne; 5, Doyenné du Comice; 6, Easter Beurré. (*J. Udale*).—1 London Pippin; 2, Lane's Prince Albert; 3, Trumpington; 4, White Astrachan. (*Walter Kruse*).—The Pear is correctly named Calebasse. The Apple Flanders Pippin. Atkins' Fancy is new to us. (*J. W.*).—1, Duc de Nemours, 2, not known. 3, Beurré De Jonghe. 4, Vicar of Winkfield. 5, not known. 6, new to us, a delicious little Pear. (*Gilbert Wootton*).—1, Beadnell's Seedling; 2, not known; 3, Beurré Amande; 4, Comte de Lamy; 5, not known. 6, Jersey Gratioli.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*F. G.*).—1, *Retinospora ericoides*; 2 and 6, *Cupressus Lawsoniana* varieties; 3, *Juniperus sinensis*; 4, *Cupressus torulosa*; 5, *Abies Douglasii*.

WINTER CORN.

AT the very beginning of another farming year we were beset by weather difficulties, for at Michaelmas the time for sowing winter corn had come, but owing to the dry weather land which had been ploughed during harvest had become so dry and hard that it could not be brought into condition for sowing till softened by rain; this was one weather difficulty. Another was that much of the land to be ploughed for winter corn was so hard that the ploughshare would not enter, and it also had to be left till rain enough fell to soften it. Meanwhile a discussion was going on in the pages of a contemporary about the respective merits of a stale and fresh furrow for sowing Wheat, just as if farming work was never the sport of seasons or weather, and we were able to prepare the soil at a given time and sow the corn to a day. What is the fact this season? Why, that we are ploughing and sowing as fast as we can without regard to line and rule. All we care for is to get the soil into a suitable condition for the speedy use of drill and harrow, so that the seed may be sown without the loss of a day.

The cultural points of real importance are these. The soil must be drained either naturally or artificially, so as to insure the speedy passage of superfluous water through and away from it. Soil that is water-logged is so inert and cold that it never can yield full or profitable crops; manure is wasted upon it, for no matter how abundant and rich may be the dressing of manure, how thorough may be the tillage, how good the seed, no satisfactory result can follow till it is relieved of the water. This done, however, Nature's treasure house is at once unlocked and the fullest measure of success is then possible if only we keep the soil free from weeds, render it thoroughly fertile, and keep it so. Is this done by farmers generally throughout the country? The best answer to this query is found in the estimates and reports of the Wheat crop of the current year. All concur in placing the average below that of last year, and this goes to prove that the corn crop in badly cultivated soil is much more liable to suffer from bad weather than that under high cultivation. If this were not so how is it that we find such a wide difference in results upon neighbouring farms? It does not answer to take things for granted and to talk of good soil and bad soil as if soil improvement were impossible.

Though the season is so much advanced the hardening of prices will probably cause much more Wheat to be sown than was done last year. If this is done well results will be satisfactory; if not, far better would it be not to sow the Wheat at all. How can we expect a full crop from soil in a half-barren condition? It is true enough that land can now be had at a very low rent, but in most cases farmers would find it answer to curtail rather than enlarge the bounds of their holdings. If it is possible for a farmer by high culture to cause one acre of land to yield as much or more than he formerly obtained from two acres, surely every sensible man would try and do so. This is the point which it is so important should have full and general recognition. How is it that a Jersey farmer with his seven or eight acres of land is able to thrive and put by money? It may be said, and well said, that a man with such a small holding is bound to cultivate it as highly as a garden to get a living out of it. Just so, then why not copy his practice and apply it to farming generally? If this were done it would lead to a more radical change both in the size of farms and in farm management. But depend upon it the change would prove wholesome and highly beneficial, for then a great improvement both in the quantity and quality of the farm would follow.

One of the best tilled and most productive farms we know is

only 60 acres in extent, and every square yard of it is turned to full account. The tenant apparently has no thought of any of his land requiring a bare fallow, but rather strives to crop the whole of it once, and much of it twice yearly. His yards are kept well stocked with pigs; by watching market sales he gets together a small flock of lambs early in the year at a cheap rate, and they are at once put upon the land in folds and kept there till ready for sale as fat hoggets in winter or spring. So by means of sheep, pigs, and horses he contrives to enrich his land sufficiently to keep it in condition for constant cropping. It is by following the ploughs and harrows closely and picking up weeds every time the soil is stirred that he contrives to keep it clean, and so avoids having any of it in fallow. We have wandered slightly from our subject, which has led up to such a train of thought, but we know that every record of good practice has its special value, and can never be out of place in connection with any subject bearing on practical farming.

WORK ON THE HOME FARM.

Enough rain has fallen to soften the soil sufficiently for corn sowing, which is now being pushed on so fast that a week or two of fine weather will enable us to finish this important work. Wheat has to be drilled with care, and the soil must be first stirred with harrows, the drill follows, and then a turn or two with harrows gives the requisite finish to the work. All seed corn is carefully cleaned and no inferior grain is sown. If we would have a full crop of really fine Wheat we cannot be too careful in the selection and preparation of the seed. After cleaning the seed it should be dressed with blue vitriol, 1 lb. to 4 bushels of Wheat. This is done by dissolving the vitriol in a quart of hot water, to which add 2 gallons of cold water. Spread the Wheat upon a barn floor, pour the vitriol water over it, turn the Wheat over a few times, and it is ready for use. On very large farms it is customary to have a tank filled with vitriol water into which the Wheat is lowered in a wicker basket attached to a pulley, by which means a large quantity can soon be steeped. Winter Beans and the last crop of winter Tares have been ploughed in. This is done by attaching a single drill to a plough, two ploughs following without drills for Beans, and one plough without a drill for Tares. The advantage of this plan is that the seed is sown at once without the use of the large drill and harrows, much labour being thus avoided, as well as any loss of time in sowing, which frequently happens if rain follows the ploughing.

The clearance of the Mangolds from the land was finished before the weather broke, and we have a fine store of roots for the lambing season. A certain quantity of Mangolds are used for the horses all through winter, the roots being minced and mixed with Barley chaff. So far as we are aware this use of Mangolds for horses is not general; certainly it is not done in Kent and Sussex, where Carrots have the preference as horse food. There is no doubt that some such succulent juicy food in winter is highly beneficial for horses.

KINVER CHEVALIER BARLEY.—We learn that at the Brewers' Exhibition, London, last week, Webbs' Kinver Chevalier Barley was awarded the champion cup open to the world, and first prize silver medal for the best malting Barley, and that this is the second year in succession that these honours have been won by this celebrated variety.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

28th.—Fine, with some sunshine; rain in evening and night.

29th.—Dull and damp early, wet day.

30th.—Wet morning, gloomy afternoon, fine evening and night.

31st.—Bright day, cloudy evening, solar halo in afternoon.

1st.—Fog all morning, rather dense early, gradually changing to rain in afternoon, heavy rain in evening and night.

2nd.—Overcast morning, wet afternoon and night.

3rd.—A dull drizzly day. Dense high fog, rendering gas necessary from 11 A.M. to 0.15 P.M. At 11.20 impossible to read the largest type close to a window, and at 11.35 in the open air a board about 3 feet by 1 foot, painted white, was invisible while within reach of the hand.

A very wet week, temperature remarkably uniform in the latter part of the week.—G. J. SYMONS.

SIMPLICITIES.

MANY practical gardeners and competent amateurs hesitate to communicate their experience because they feel it is of a common-place nature, and that the narration would neither display their erudition nor scientific accomplishments. That is a mistake. Some years ago a gentleman desired what his gardener was not producing for him—good Grapes. The man thought himself, and endeavoured to convey, that he was a scientific gardener, and discoursed learnedly by way of explanation about the principles on which his practice was based, not omitting sundry references to the action of oxygen and carbonic acid gas on vegetation. He was, in fact, talking the master over by a process of mystification, but was met with the stinging retort, “I hear what you say and wish you to understand that I would rather have less gas and more Grapes.” That represents the desire of the vast majority of owners of gardens. They want good produce of various kinds in season, and often as much out of season as means allow, and sometimes more than they will permit. This latter is an unfortunate contingency, and beyond doubt it would be a great advantage if the true resources of gardens were appreciated by their owners, as this would in many instances result in a modification of expectations, and a man who is worth his salt will strive to the utmost of his power to make the garden of a considerate master both pleasurable and profitable. He cannot do this without going into the simplicities of his vocation, for these form the basis of success.

Indoors and out and at all seasons what are known as simple duties must be performed, or satisfactory results cannot be achieved. What is more simple, for instance, than sowing Peas? yet what is more important than a full supply of pods for gathering at the earliest possible date? and what more disappointing than being a week or ten days later than a neighbour who grows them under similar conditions, but differs in his methods? Years ago the good old kitchen gardeners rarely failed in the first early Pea crop by simply sowing in November, but some advanced gardeners of the present day appear to think the old practice obsolete, hence they sow in pots in frames, “gradually harden the plants,” then plant them out and shelter them as if they were so many bedding plants. No doubt the plan of first making young Pea plants tender then “hardening” them answers or it would not be practised and advocated; but this does not prove the failure of the old method of sowing in the open and letting the plants assume a hardy character from the first; and though a few rows may fail now and then, if too advanced when a sharp spring frost occurs, those raised in pots and planted are liable to be similarly injured or destroyed; and it is an open question if more of these are not damaged than of the others that have passed through the winter in the open ground.

Some gardeners who have been “brought up” where every convenience in the way of frames and other glazed structures were provided, have arrived at the conclusion that it is of “no use sowing Peas in the autumn nowadays,” and therefore raise all the plants for their early crops “under glass,” just as there are other men who are firm in the belief that the days of successful Peach culture on open walls are gone for ever “because the seasons have altered.” Are these propositions, as the lawyers say, true in substance and in fact? Are there not gardeners a hundred miles north of London, and even more than twice that distance, who seldom fail to have good crops of Peaches on garden walls, the fruit ripening well, and in quality equal to that grown under

glass? And are there not other gardeners who sow Peas in November with as much confidence as their fathers had that in due time good crops would be ready for gathering during the last week in May or early in June, according to the season—crops even more abundant as a rule than those borne by plants raised in pots, according to the modern course of procedure?

As to the failure of Peaches outdoors, it is not the “seasons” as a rule, but insects, that lead to failure—aphides at the outset retarding the growth then, which is equal to a loss of time that may be counted by weeks, and can never be regained; then in hot summers comes the scourge of red spider, arresting growth, and depriving the trees of juices that are essential to their health and fruitfulness. Is not this shortening of the season at both ends sufficient to account for the failing of Peaches on walls? The “seasons are altered” with a vengeance, but altered by insects that were permitted to increase by the forbearance of man, who did not see the importance of having recourse to preventive measures, but preferred to wait till he had something to kill—that “something” in the meantime ruining the trees. All that is very simple, but the more it is thought about the more clearly it will be found to be true; and if the fact was not appreciated before, evidence is at once afforded of the tendency of even generally close observers, and in many ways able men, to overlook simplicities. These cannot be ignored with impunity, for the neglect of small matters at a critical time has often far-reaching effects, and a penalty has usually to be paid in some form or other for the omission, sooner or later, trifling or serious, according to results and the special circumstances surrounding each case.

November sown Peas fail if raised too early, and also if the work is unduly deferred. “Do not sow before the 5th of the month nor after the 20th” was the advice of one of the best kitchen gardeners, who during thirty years of practice was able to say he had never failed in his early Pea crop. If sown before the date first named the plants are liable to get too forward; if sown after, and a term of cold and wet weather sets in, much of the seed is apt to decay. The method of sowing is also important. It was pitiable to see a man the other day trampling the soil of a south border into semi slush, the earth adhering to boots and implements like so much birdlime. Yet he was sowing Peas, and if the crop fails, as it may, it would be curious to hear from the cultivator the cause to which he will attribute the failure.

There are only two ways of sowing Peas at this season of the year that indicate good workmanship, and can be trusted to answer the purpose in view. One is to dig the land on a dry day, sowing as the work proceeds; the other to make the drills and sow from a wide board, pointing up the compressed surface after the board is turned over. Nothing could be simpler than that, but the simplicity is not to be laughed at. The great point to secure is the free passage of water and air through the soil, and the little matters alluded to contribute to that end, while the rough trampling plan frustrates it. Bearing that in mind, the habit of treading the drills for Peas that may be practised in summer with impunity, is in most soils, and certainly in all of a retentive nature, a plan to be avoided in November. The drills should be level undoubtedly, but light and porous so that the rain can freely filter through instead of being retained where it could not possibly do good, and might do considerable harm.

One or two other precautions are taken by gardeners who are successful nine years out of ten with the crop in question. If the ground is wetter than they wish, yet the date late and the work must be done (through the possibility that by waiting longer would be to fare worse) they spread half an inch or so of dry soil for the Peas to rest on, and cover them with a similar layer before levelling in the natural soil. That may appear a trifling matter to refer to, but failure is no trifle, and the simple provision mentioned has often been a chief factor in the success accomplished. Another little matter, notwithstanding its simplicity, is worth noting for the benefit of the young and inexperienced, as these are always with

us, and it is to be hoped always will be—namely, the depth of covering the seed. This may be buried 4 or 5 inches deep in late spring and early summer without any ill effect: but it is very unwise to act similarly in November. A simple plan proved sound by a generation of experience is to cover the seed an inch deep, or a little more if the soil is light and porous, then spread an additional inch of ashes on the surface exactly over the rows and extending a couple of inches on each side wider than the drills. This covering serves three or four good purposes—its porosity, admitting water and air; its sharpness, making a good barrier against mice in winter and slugs in spring; and its dark colour absorbing more of the sun's rays than the soil can possibly do that is many shades lighter in hue; or, in other words, the Peas lie warmer under the ashes than they would without them, and growth is quicker after the winter has departed, because the earth is warmer through their influence, and in obedience to the same law that makes black coats and hats warmer than light ones when the sun shines on them.

All this is very simple, no doubt, to many, and mere rudimentary truth; but there are others who have not thought about the great influences of little things, and are seldom led to do so by the teaching of their elders. Yet is it not correct to say that men who become the most competent in their calling are those who take the greatest pains in their work, no matter what it may be? No item is too small for them to consider, no work too simple for them to do, and it is because they digest the items and master the simplicities that they accomplish with apparent ease the fame that is their reward. "It must be easy to paint a picture like that," observed an on-looker to a famous artist, who with quick and easy freedom was displaying his skill. "Oh yes, quite easy," was the comforting reply, "You have only just to mix the right colours, and put them on in the right places, and the work is done." That was easy to the artist, who, we may be sure, had overlooked nothing however small, that had contributed to the education of the eye and hand.

And so it is with others, including gardeners, and in none more than those who have good crops of Peas by sowing in the autumn, good crops of Peaches on open walls, not to mention the men who win the first prizes with Chrysanthemums in the best competition in November.—EXPERIENTIA DOCET.

APPLES AND PEARS IN WALES.

WALES was not well represented at the late Chiswick Conference. I know one at least who worked hard to reverse this, but it was not so much the unwillingness of growers as their inability that prevented exhibits being forwarded. As viewed from Wales, or indeed from anywhere, Chiswick is a great place. Growers in Wales who have any respect for themselves and their country do not care to send specimens for exhibition to London unless they are representative of the average production, and as a rule Apples and Pears have been much below the average in quantity and quality in the principality this year. At the best of times Wales is not a first-rate fruit country, but this, be it fully understood, is not so much due to want of skill in culture as to a marked deficiency of natural adaptabilities. In many cases there is no overcoming these, as the soil and climate—not the natural climate, but that produced by the development of different forms of industry—are so antagonistic to Apples and Pears generally that all attempts have proved futile. There is no class of people more anxious to grow good fruit and plenty of it than the Welsh, and I have often felt sorry after I recommended amateurs to plant trees to find that they failed prematurely or nearly so from canker and other causes that are unheard of in many of the best English growing fruit counties.

Small fruits are abundant, and it would be difficult to surpass them. In good Apple and Pear years many gardens in Wales will hold their own in the production of fine fruit, but this year, besides being deficient, they are below the average in size, and they do not display much quality. A good indication of this was noticed at the summer and autumn shows, where Apples and Pears were worse than I have seen them for a dozen years. Glamorganshire is one of the poorest Apple and Pear counties, but Carmarthenshire is better, and so is Pembrokeshire, as neither of these counties is so much overrun with works and the consequent vapours as Glamorgan,

and I do not know of any reason why Carmarthen and Pembrokeshire should not be as profitable fruit counties as Hereford, Gloucester, Somerset, or Devon. The climate is favourable, so is the soil generally, and judging by the fine crops in small gardens in Carmarthenshire and Pembrokeshire I think fruit culture might be extended there to advantage if proper varieties were selected and carefully planted.

There is abundance of room for improvement on the present system of culture, as this chiefly consists of retaining old trees that have long passed their best, giving them little attention and showing but small inclination to introduce new and improved sorts. I hope that the movement that is awakening English landowners to the advantage of improved fruit culture will have some influence in Wales; but it is not so much professional gardeners that will be benefited by it as amateurs and farmers. When I go from home and pass through some of the English counties where many of the hedgerows and fields are studded with Pear and Apple trees a profitable system of culture is indicated which we could not see imitated during a week's travel in Wales. I should like to see many of the existing Apple and Pear trees destroyed. They are too old, cankered, and debilitated ever to produce fruit that would be regarded as good at any future conference. Their place should be taken by healthy young trees of sorts noted for their free bearing and good qualities everywhere. I would not have those who have proved Apple and Pear culture to be a failure under their circumstances attempt it again, on an extensive scale at least, but where the situation is away from the influence of the works, and there are many such, Apple and Pear culture should be begun and energetically followed up at once. At present the bulk of the Apples and Pears used in Wales are imported from the western counties of England, the demand for them is very great, and the prospect of every Apple and Pear that anyone cares to grow in Wales being readily and remuneratively bought up is as bright and encouraging as could possibly be desired.

Of late years I have induced some farmers to plant rather extensive orchards in various parts, and it may interest others who are inclined to do likewise to know that so far they are delighted with the results, and I have every confidence that in years to come they will be still more so. Those which are doing best are in cases where considerable attention was given to selecting and preparing the ground and buying good trees. The varieties I have noted as doing best in Wales are, Apples—Lord Suffield, Kerry Pippin, Hawthornden, Stirling Castle, Peasgood's Nonesuch, Golden Noble, Warner's King, Dumelow's Seedling, King of the Pippins, Northern Greening, Keswick Codlin, Court of Wick, Cellini, and Cox's Orange Pippin. Pears.—Bonne d'Ezée, Beurré d'Amanlis, Beurré Diel, Beurré Rance, Louise Bonne of Jersey, Souvenir du Congrès, Passe Colmar, and Josephine de Malines.—CAMBRIAN.

PLUMIERIAS.

I WAS much interested in reading the article in the Journal upon the Plumieria, and possibly, as you say that the plant is not much known, a few remarks may be acceptable to some of your readers. I was, however, under the impression that there is a fine specimen of the plant at Kew, as some years since my brother-in-law, Sir J. F. Dickson, whilst resident magistrate at Anaradhapura in Ceylon brought me some cuttings which, if my memory serves me well, my late gardener, Mr. W. Wright, identified from the plant in the Kew collection. It is really a tree and not a bushy plant, and being held as sacred to Buddha is usually planted in the enclosures of the Temples, from which it derives the name by which it is ordinarily known—Temple Tree—and the flowers are presented as offerings to the god. The flowers furnish also the scent known as Frangipani. The habit of the plant is to flower before the new growth commences, and after blooming the branch divides into three shoots. The flower stalk is produced from the central axis of the branch as a strong single growth for about 2 inches, which divides into three or four smaller stalks, each with a row of buds on the upper surface, and the buds open successively on the stalks, so that it seems rare to find more than two at a time open on the same stalk. I presume from seeing the full cluster that is shown on Mr. Cannell's plant that it may be some different species to ours, of which I enclose a photograph, and I understand that our plant is decidedly flowering out of season, as it has bloomed immediately after making growth. Sir Frederick Dickson tells me that he believes the botanical name of our species is either *P. longifolia* or *lanceifolia*, but he does not remember which.—C. M. MAJOR, *Cromwell House, Croydon*.

[The photograph received is very good. So far as we remember the flowers produced by the plants at Cromwell House were not quite so large nor so intensely yellow as those sent by Mr. Cannell

and illustrated on the page cited. We thank Mr. Major for his interesting communication.]

YOUNG VERSUS OLD FRUIT TREES.

WITHOUT wishing to depreciate the value of some large old fruit trees, which under good culture frequently yield large and profitable crops, I am yet disposed to assert that, as a rule, much younger trees are more to be depended upon. In very many instances the old giants are mere lumberers of the ground. It is only occasionally they bear anything approaching a heavy crop, and very rarely indeed is the quality of the fruit other than second rate. When these large old trees happen to be the survivors of what was once a well stocked orchard there is no great wisdom in destroying them, as they afford shelter or shade to stock grazing near them equally as well as ordinary forest trees, and in addition will yield a certain amount of fruit, which may be utilised in various ways. But when valuable garden or wall space is taken up by old and comparatively valueless trees the case is very different. Five old Pear trees against walls, if the variety is worth preserving, ought not to be too hastily condemned, as it is quite possible to reinvigorate these by gradually lifting and shortening the principal roots, relaying these in fresh loamy compost. Nor would I cut down fairly large specimens of useful Apples before making an attempt to renovate them. For instance, that most valuable Apple Blenheim Pippin is rarely very fruitful till the trees have attained a large size, and such must therefore be taken more care of. Not many fruit growers could afford to partially lift and give much fresh soil to large Apple trees, but quite recently I saw a fine tree of Blenheim Orange that had been once condemned and then repited to see what good could be done with a heavy surfacing of solid manure. This tree is now carrying a profitable crop of fruit after having failed for several years past.

I give the foregoing advice upon the retention of old favourites by way, however, of exceptions to the rule, as, according to my experience, old and slowly decaying Apples, Pears, Plums, Cherries, Apricots, Peaches, and Nectarines do not give adequate returns for any trouble taken with them. It does not follow that these should be rooted up wholesale, but, on the contrary, it is generally unwise to destroy one set of trees before others are ready to take their place. Any intended improvements in the way of substituting young trees for old ones ought to be anticipated one or more seasons in advance, or in other words young trees should be bought and prepared as much as possible in the time allowed to take the place of those rooted out. This is, unfortunately, not possible in all cases, many persons having a most inexplicable objection to their gardeners purchasing trees before it is absolutely necessary; in fact, there are numerous badly furnished walls in this country that are so entirely owing to this mistaken notion of economy. Those who imagine that it is useless for them to plant trees, seeing that there is little likelihood of their enjoying the fruit, err greatly. Proprietors of gardens and orchards are not a particularly short-lived race, and it is surprising how soon a tree attains a fruitful size, especially when it is not watched too closely, because the "watched pot never boils." Those who are most apt to grumble are the owners of gardens where very many of the trees are young. Let young trees be planted always in advance of the decay or clearance of the old ones, and the change will gradually be effected without any perceptible falling off in the supply, the quality gradually improving according as the healthy specimens arrive at a bearing state.

Occasionally we see gardens where the walls are so well furnished as to render it a difficult matter to introduce young trees between them, but as a rule there are plenty of suitable vacancies for the preparation of youngsters, and these ought to be utilised to their full extent. It is even desirable to introduce fresh trees where the garden is already well stocked, with the aim of improving the selection. There are always some failures either as regards the well-doing or the quality of the fruit of certain varieties, and with good trees of newer or better varieties at hand there is less hesitation in rooting out a healthy yet unprofitable specimen. Apricots, Peaches, Nectarines, and in a lesser degree Plums and Cherries, are very liable to lose whole limbs or the best portion of the tree from gumming or other causes, vexatious gaps being the result. With plenty of young trees ready to pop in where required the wall space is soon refilled, and much annoyance avoided. In the case of all trees to be grown in the open garden or orchard there is less excuse for neglecting to plant a few occasionally, as such do not encroach seriously on the garden ground. It is not my intention in this paper to discuss how many years it takes for a tree to arrive at a free bearing state, and will only repeat they are by no means necessarily planted for the sole benefit of those who come after us.

Which is the best form of tree and the most suitable stocks

could not well be stated in a brief compass, so much depending upon circumstances; but as a rule I prefer to purchase medium sized well ripened maiden trees, or those which have not been cut back. These invariably form the healthiest trees, and soon surpass the majority of those that have been repeatedly pruned and trained in the nurseries. This is no novel idea, nor is it advanced from any desire to prejudice nurserymen in any way. The fault is not theirs, as they must prune and train as long as they have their trees in stock, and we have only ourselves to thank if we plant much-pruned, or it may be large yet stunted examples which do not take kindly to their fresh quarters, or which, perhaps, will canker or gum badly before they have long been in position.—W. I. M.

CYPRIPEDIUM FITCHIANUM.

IN the last issue of the "Orchid Album" Mr. B. S. Williams gives the following description of the above-named hybrid Cypripedium.

At the present time the genus Cypripedium is exceedingly popular, and new forms are continually appearing through importations from abroad, as well as from the work of the hybridiser at home; indeed, the crossing and recrossing of the different species and varieties appears to be a favourite pursuit with amateur growers, as well as those connected with the trade in orchidaceous plants, and from the result of whose work many excellent, new, and beautiful varieties have emanated, whilst from the experience gained in previous experiments, many other and superior forms may be confidently anticipated. Cypripediums are amongst the easiest of plants in the whole order to fertilise, and for this reason they have been taken in hand by the many. They also come freely from seed, and in most instances are robust in constitution and produce flowers in a young state, so that it is little wonder that they are very popular, especially as many of them produce showy flowers, although in a different degree of excellence, which continue long in full perfection. Many beautiful species and varieties of this genus have already appeared in the "Orchid Album," but there are many more which we hope to introduce in the same manner to the notice of our readers.

The plant is one which we had the pleasure to introduce to commerce in the spring of the present year, and which we have named in honour of our artist, Mr. John Nugent Fitch. It is the result of a cross between Cypripedium Hookeræ and C. barbatum. It is a very free grower, and also a prolific blooming plant, thoroughly distinct, both in foliage and flower, from any other kind known to us.

Cypripedium Fitchianum is a distinct and pretty variety, and compact in its habit. The leaves are oblong acute, from 4 to 6 inches in length by about 1½ inch in breadth, and prettily variegated; the ground colour is greyish-green marbled and spotted with deep olive green. The scape rises well above the foliage and bears a single large and handsome flower; dorsal sepal somewhat ovate cuneate, white, conspicuously veined with bright green, the lower sepal being similar in colour, but smaller; petals long and strap-shaped, with blunt ends, green towards the base, the apical portion and the margins being suffused with deep red, and bearing a few black hairy warts on the edge; lip large, dull red, veined in front with green, the inner surface profusely covered with dots and spots of red. It blooms in the winter months, and continues in perfection for fully six weeks.

We think this variety of Slipper Orchid thrives best in the East India house, as may have been anticipated by a knowledge of its parents, which are both natives of warm places in the east, but we find that this, and the majority of the other members of this genus, succeed best when shaded from the direct rays of the sun during the hotter part of the day, although they enjoy full exposure to the light, and we have recently observed great improvement in the health of the plants in one or two collections, where these plants have been subjected to a greater amount of shade from the sun than was formerly given them. Perfect drainage is essential to the health and well-being of Cypripediums, as during growth they enjoy copious supplies of water to their roots, which, however, requires to be passed away quickly; a slight syringing overhead in the morning, and again in the afternoon during the growing season, will be found highly advantageous. The potting material should consist of good peat fibre and living sphagnum moss. These plants

do not require a lengthened period of rest, but during this time syringing must cease, and a considerable reduction made in the quantity of water supplied to the roots, but even at this season they must not be dried, or evil results will follow.

Insects should be carefully watched for, and speedily destroyed if they make their appearance on the *Cypripediums*, or their leaves will quickly become marred and disfigured, and the plants fall into a sickly condition. Black-thrips and red spider are amongst their worst enemies, but these may be effectually kept in abeyance by steaming the house occasionally with tobacco-juice from the *thanatophore*.

DR. PATERSON'S ORCHIDS.

On the 10th inst. I had the pleasure of looking into Fernfield, Bridge of Allan, of having a "crack" with the worthy Doctor, hearty and enthusiastic as ever, a sight of the latest additions to his wonderful collection of "auld airn nacksits" and valuable curiosities, and an inspection of the Orchids. Visitors daily turn into Fernfield, but I fancy it is not every day that the Doctor among them in a group of four embraces at once a blooming lass of sweet nineteen and a wondrously hale old gentleman of ninety-four years. The houses are again all but filled with young Orchids in the Fernfield state of health, and will before very long need all the accommodation at command. With others in bloom I found about a score of *Cattleyas*, including *C. Gaskelliana*, *C. Pereivaliana*, &c.; *Masdevallia ignea*, *M. Lindeni*, *Maxillaria pieta*, *Miltonia spectabilis*, *Odontoglossum Alexandræ*, *Oncidium cucullatum*, *O. macranthum*, *O. Marshallianum*, *O. unguiculatum tigrinum*, *Phalenopsis grandiflora*, *Pleione lagenaria*, *Vanda tricolor*, *Zygopetalum Mackayi*.

In the open flowers were still plentiful. In a hasty glance I observed *Chrysanthemums*, *Rose Souvenir de la Malmaison* and others, two lines of *Yucca filamentosa*, *Tropæolums* in profusion, *Phloxes*, &c., and everything was, as usual, in apple-pie order.—
A NORTHERN AMATEUR.

THE JENSEN SYSTEM OF MOULDING POTATOES.

DURING two successive seasons elaborate experiments and careful observations were made as to the effect of the Jensen system of moulding. The experiments were made at Chiswick under the superintendence of the Scientific Committee. Although results of considerable practical interest were obtained, yet the primary object of the experiments was frustrated by the non-appearance, or, rather, by the scanty development of the Potato mould. Moreover, it became apparent that the cost of the experiments, as then carried out, would be such as to preclude their imitation on a large scale for practical purposes.

During the present season the Potato disease set in at Chiswick with virulence about July 29th. Up to that time no attempt had been made to check its course or to note the conditions under which it occurred; but at the suggestion of Mr. Plowright two rows in juxtaposition were submitted to experiment on August 10th.

Two rows were 30 yards in length, the variety selected *Schoolmaster*, and the conditions as absolutely identical as possible, except that the one row was left moulded in the ordinary way, while the other was "high moulded"—that is to say, banked up on one side to form a ridge, while the haulm was slightly bent over to the other side. In the ordinary system of moulding a furrow is left along the top of the ridge into which it is surmised that the spores fall, washed off by rain from the foliage. The high moulding, it is supposed, obviates this by securing the fall of the spores on the ground between the rows, and not on the rows themselves. As the disease appeared to be equally severe on both rows, and was, moreover, far advanced, but little expectation was indulged in that the results would be of any value.

Nevertheless, on September 29th, the Potatoes in the two rows were lifted and examined, as dug, by Mr. Barron and Dr. Masters. It speedily became apparent there was a considerable difference between the two rows, and that the tubers from the high-moulded row afforded a much cleaner and more even sample. With a view to put this general impression to a numerical test, fifty tubers from each row were taken indiscriminately—twenty-five by one observer, the remainder by the other, so as to equalise, as far as possible, the "personal equation."

These hundred Potatoes were then examined with a more careful scrutiny, each one being cut open to ascertain whether or no it was diseased. The result was as follows:—Out of fifty taken from the row moulded in the ordinary way, thirteen were found diseased, or 26 per cent.

Out of fifty taken from the high moulded row five only were noted as diseased, or 10 per cent. No doubt a more careful examination by the microscope would have indicated a larger proportion of disease in each case, but it is not likely that it would have very materially altered the proportion either in one direction or the other. In order, however, to obtain further information upon this point, twenty-five tubers from each row were put aside for future examination. Of fifty tubers set aside at the time of lifting to show how many would show disease subsequently, the result is now—ordinary moulding, thirteen tubers diseased, twelve sound; high moulding, all sound.

HYBRID PERPETUAL ROSES IN POTS FOR FORCING.

THE reason many fail with these Roses in pots is simply because they commence forcing them before they are thoroughly established. No greater mistake can be made, for the plants make only puny growth and produce the poorest flowers. This is not all, for they seldom succeed satisfactorily afterwards. They are ruined to start with, and those who wish to attain success in their culture will be wise to establish the plants thoroughly in pots, and then, if they are required to bloom early, to train them with the same care as *Azaleas* or *Camellias* require. Start the plants earlier each year, which will enable them to make and ripen a good growth, so that they have time to rest before being pruned.

Whether the plants have to be purchased, or home-grown plants are lifted, potting should not be delayed until the autumn has advanced and the plants are destitute of foliage. Very often when potting is delayed severe weather sets in and delays the operation longer than cultivators might desire. There are others who think all will be well if the plants are potted any time during the winter, or before they show signs of growing in early spring. Such notions would soon be obsolete, if the trouble was taken to pot one lot of plants in October and another in February and then compare the results.

It has been said by certain cultivators that they have lifted plants at the end of November and during the following month and have forced them successfully, the plants yielding very fine blooms. I do not doubt this, but it would be interesting to know what is meant by forcing. If the plants produced fine blooms I am mistaken if they did not allow them to come forward in cold frames or cool houses under almost natural conditions. I do not term protection by the aid of a cold frame or cool house, forcing. I have had good flowers from plants planted outside in December, but have always been of opinion that I have had better from those planted in October, and finer growth the first season.

I have always found some difficulty in getting Roses from nurseries for potting as early as I desired, and could never make out the reason. On two or three occasions, perhaps more, I have had a polite note saying they had not commenced lifting, the plants were scarcely ready. But when I purchase again I shall be prepared to take all risk, and shall have my plants from the middle to the end of October according to the season. A few soft young growing shoots on the top need not alarm anybody. When getting the plants from a distance the only risk to fear is that of the roots being dried before they are packed in damp straw. I have had plants from a distance and potted them at once on arrival; the foliage has remained fresh for a very long time afterwards, and they have made quantities of roots that have reached the sides of the pots before the end of November. Plants lifted at home have certainly the best chance, but if obtained from the trade early, and the plants receive proper treatment afterwards, they will not be far behind when the season for flowering arrives. I prefer the trade size plants to start with, and think they do better in the end than larger but older plants that may have been growing without being disturbed for some years.

When ordering plants it is wise to specify that they are required for pots, and those worked close to the root will be sent. I would not pot dwarfs that have a long stem, but all the principal growers work as close to the root as possible now. The *Briar* is decidedly the best stock on which to grow Roses in pots. The plants as a rule are not quite so large as those worked on the *Manetti*, but they start better the first season, and in the end make the best plants and last in good condition considerably longer.

For plants of the ordinary trade size 7-inch pots are the most suitable at first. These should be well drained by placing one good crock at the base, hollow side downwards, and then a number of smaller pieces round and over it. Over this place a little fibry loam to keep the smaller particles of soil from intermixing with the drainage, and on this a pinch of soot, which will act as a preventive against worms entering the pot through the hole at the base.

The plants need as a rule very little preparation. The unripe ends of the shoots are removed, and straggling ones cut back, leaving them about 2 feet long. The roots will need trimming; damaged portions should be cut back to where they are sound with a sharp knife, and strong fibreless roots may be well shortened back.

The soil must consist of good fibry loam of an intermediate nature between light and heavy; if the former, dry some clay and reduce it to powder and then add it to the loam. In this condition it can be mixed

freely and evenly; if the latter, add coarse sand, charred soil—anything that will keep it open and porous. To the loam add one-seventh of decayed manure, one 6-inch potful of soot to each barrowful of soil, and the same quantity of quarter-inch bones with the dust left in. The soil must be in an intermediate state of moisture; this is important, for if the plants are treated as I shall advise they will need no water at their roots until after they are pruned, if then. If the soil is dry it will be necessary to water the plants, but it is better to water the soil before it is used and throw it into a heap for some hours, and then turn and mix it thoroughly. On the other hand, the soil must not be used too wet; this is a much greater evil than the other, for if the plants are potted in wet soil they are seldom satisfactory. Potting is a simple process. The union of the stock and Rose should be just below the surface of the soil when the plants are finished, say half an inch. The soil should be pressed moderately firm into the pots.

A very usual practice with cultivators after the plants are potted is to stand them outside. This necessitates frequently watering the plants and does them considerable harm, besides washing away food supplies from the soil that will be required by the plants the following season. They make few, if any, roots when subjected to this treatment, and in addition must be placed in frames directly a few sharp frosts are experienced for fear of injury to the pots. The best plan is to plunge the pots in ashes, there is nothing better, covering the rim of the pot and surface of the soil. If this is done all the attention needed will be to syringe the plants during dry weather to insure the foliage remaining fresh. Water at their roots will not be required, evaporation is prevented, and the soil remains in about the same state of moisture when they are placed in frames as when they were first potted. This treatment suits the plants admirably, and they make fresh roots quickly. Before it is necessary to place them under cover—which can be done when convenient, for the pots are safe against frost—the roots will have reached the sides of the pots; in fact they will be sufficiently established to make a vigorous growth and produce fine blooms. The weather alone should guide the cultivator when to give the plants cold frame protection. Moderate frost will do them no harm, but if very wet weather sets in they are better in frames than outside. If the pots can be plunged in the frames all the better, but this is not important. The lights of the frames should be drawn off during fine weather.

The plants may be pruned the last week in January or the first in the following month, the shoots being well cut back and not left 6 to 8 inches in length, for they seldom break from the base, and therefore no advantage is gained. Two or three eyes on each shoot are sufficient. The plants may be arranged where they are to grow and the pots plunged to the rim. Each plant should have room to develop without being crowded. If they come forward under the influence of plenty of air they will make sturdy growth, fine foliage, and flower at the end of April, or they may be sufficiently retarded to just precede the outdoor supply. In this case they need not be pruned before the end of February. When they have flowered they can be plunged outside and placed during June or the early part of July into 9-inch pots. At this stage I will leave them, for if well cared for they will be in good condition for flowering in March the following season. Suitable varieties will be found on page 401 in the issue for May 17th last.—W.M. BARDNEY.

DEEP PLANTING.

A POINT in Rose-planting, which I believe to be of the utmost importance, is the depth at which the roots are laid out. It is desirable for all budded dwarfs, and necessary for those on Manetti, that the union of scion and stock should be beneath the surface, that the Rose may form roots for itself; but, with this proviso, my advice would be, Plant as shallow as you can.

A good rule to remember in the transplanting of all trees and shrubs is not to plant the tree deeper than it has been hitherto. And as dwarf Roses are budded at the nurseries not more than half an inch below the surface, and frequently above it, I believe that to plant so deeply as to bring this junction 3 inches below the surface (as I have lately seen recommended) is always hurtful and frequently fatal.

I have witnessed during the past week the lifting of some Briar cutting Roses which were put in as fine plants this time last year. They proved a great failure, some actually dying, while the remainder just lived, and that was all, though old-established plants in the same bed with the same treatment did remarkably well. On lifting the cause of failure was, in my estimation, plain. The union of stock and Rose was about 3 inches more or less in each case below the surface, and the roots had been not "planted" but "buried."

Sometimes we get dwarfs sent us which have been budded too high, the union being 2 or 3 above the roots. If on Manetti I should consider such a plant worthless. A Rose on a long leg of Manetti could only be planted horizontally, and is practically of no use. If on the Briar, and it be determined to try it, I would not attempt to cover the union of Rose and stock, but plant the roots at a proper depth and let it take its chance. It may do well, though it has not as good an opportunity as it would have had if budded lower.

In planting Roses separately, or filling up gaps, it must be remembered that the freshly disturbed soil will sink, especially if the hole made be deep, or much manure has been added, and that the plant will sink with the soil; an allowance of half an inch at least should be made for this. In a general way I should consider 3 inches to be deep enough for any Rose roots; and indeed I have always found that,

provided they are deep enough to be well out of the way of the hoe, the roots of Roses which are well cared for cannot be too near the surface.—W. R. RAILLEM.

TRIDAX BICOLOR ROSEA.

THE yellow-flowered Compositæ are so numerous in late summer and autumn that it is quite a relief to obtain any additions to the

FIG. 50.—TRIDAX BICOLOR ROSEA.

family in which the flower heads are of some other tint. The Zinnias and the Asters afford some of the best known examples of the diversely coloured Compositæ; but the plant to which attention is called in the woodcut (fig. 50) and this note, is by no means familiar in gardens. At Kew this year it has been very attractive, and it evidently is worthy of a place with other border plants from the great western Continent. The

flower-heads are of moderate size and neat shape, white with a strong suffusion of deep clear rose—a peculiarly bright and pleasing tint. They are freely produced. The plant is compact, of moderate height, and of easy culture.

MR. GEO. BUNYARD'S NURSERY, MAIDSTONE.

KENT is justly styled the Garden of England, and we men of Kent do not intend to yield the palm to any other county, and of this county there is no richer or in its way more beautiful portion than that which surrounds for some miles the county town of Maidstone. The soil generally is of that rich unctuous loam in which so many plants rejoice. Even Rhododendrons and Conifers, which are sometimes supposed to rejoice only in sand, flourish here as well as they do in the sandy hills of Bagshot, while it is a very Paradise for all kinds of fruit trees. Since Mr. Geo. Bunyard has taken the Maidstone Nursery in hand each year has seen additions and improvements, and here at any rate the Secretary of "the Fruit Growers' League," whatever that may be, will find no worthless trees, no inferior stock, but a large number of the very best varieties in cultivation. There is no doubt that a few years will see a complete revolution in our fruit culture, although it is very hard to drive into the minds of some people, that the old worn-out and cankered trees should be rooted up and young ones of good sorts planted in their stead, while owners of private gardens will surely see the wisdom of planting kinds that will be satisfactory both to eye and palate.

Mr. Bunyard kindly met us at the Barming station, on which his nursery abuts, and we then began our round. It must be remembered that the nursery is a very extensive one, and shaped somewhat like the letter U, and that by the time you have got round it you have accomplished a good afternoon's work. As my object was to see the fruit trees I must leave unnoticed many other interesting parts of the garden, where trees, flowering and evergreen shrubs, herbaceous plants and other things are exceedingly well grown. Some idea of the extent of these nurseries may be had when I say there are 400,000 fruit trees of various kinds. Of Apples alone there are 120,000. Some are cordons on the Paradise stock, then there are pyramids, bushes, and standards, while the growth in maiden trees was something remarkable. It is well known that this is not an Apple year, yet no one would think so who saw the beautiful little trees in this nursery—trees laden, although only 3 feet high, with richly coloured and large fruit. Taking the culinary Apples first, these were evidently most in favour with the public, and Mr. Bunyard had taken good care to meet that taste where it was correct, for a good nurseryman has not merely to follow the public, but, to a certain extent, to guide it. If anyone comes into a nursery to order trees and mentions some indifferent sort, the vendor will say, "Yes, I can supply it, but there is so and so, a much better Apple, which I would advise you to have." There are thus large breadths of such sorts as Manx Codlin, Duchess of Oldenburg, Worcester Pearmain with its lovely high colour, Grenadier, Lord Suffield, Potts' Seedling, Yellow Ingestrie, Ecklinville, Cellini, Stirling Castle, Bismarck, a most remarkable Apple, a new introduction from Australia; the fruit large and highly coloured, and the tree very productive. Then there are Gipsy King, Domino, Lord Derby, Lord Grosvenor, Mr. Gladstone, Colonel Vaughan, Calville Rouge, Lane's Prince Albert, Cox's Pomona, Small's Admirable, Alexander, Warner's King, Peasgood's Nonesuch, Mère de Ménage, Alfriston, and other fine sorts. But perhaps the most useful and best of all our kitchen Apples is Wellington or Dumelow's Seedling, a late and long keeper and well-known kind. And this is, I think, what must be aimed at in the future of Apple-growing in England. We are inundated with early Apples, but we want such kinds as will take the place of the American Apples, which do not commend themselves to our taste when we can get anything else; but Wellington is a sharp, well-flavoured Apple, not with that flat taste which most of the American Apples have. Of dessert Apples there were also some fine quarters, Irish Peach, Ribston Pippin, Cox's Orange Pippin, and other fine sorts. What a deal of nonsense people write about the Ribston Pippin dying out. Let anyone who writes this sort of rubbish only pay a visit to Mr. Bunyard's nursery, and they will be soon disillusioned; there are in fact in the whole of the nursery no healthier and better trees than those of this old and hardy fruit, but which I believe to be eclipsed by Cox's Orange Pippin, equally good in flavour, and not so hard to digest. But the finest examples of fruit were to be found on the potted trees, whether plunged outside or in the orchard house; these latter were perfect pictures, laden with handsome and highly coloured fruit, showing how great are the capabilities of a well-managed orchard house. Amongst these were Belle Portoise, a new and promising variety, of which Mr. Bunyard thinks very highly; Golden Noble, New Hawthornden, Peasgood's Nonesuch, and many of the varieties named above. Amongst early Apples Lady Sudeley was prominent, and is likely from its beautiful appearance, fertility, and excellent flavour to become popular. It would be tedious to enumerate the many excellent examples of the very best sorts to be found here, but suffice it to say that when the Apple and Pear Conference have put before us what they consider the best this nursery is one of those where their wants can be supplied.

In Pears the nursery is equally rich, although as the Pear has not the economical value of the Apple, it is not so numerously represented, for while there are 120,000 Apple trees, Pears are only 35,000. They are cultivated on the Quince and Pear stocks. Great care has been taken to select the stocks which experience has proved to be best suited to each variety. There were large quantities of Williams' Bon Chrétien, Clapp's Favourite, Souvenir du Congrès, Triomphe de Vienne, Doyenné du Comice,

Fondante d'Automme, Durondeau, Beurré Hardy, Beurré Baltet père, Colmar d'Été, Pitmaston Duchess, &c. These are to be had as pyramids, bush fruits, and cordons, and were in excellent health, although Mr. Bunyard has had to complain, as many of us have this year, of fruit cracking, especially such kinds as Doyenné du Comice. This is to be attributed I believe to the check which the fruit received during the cold and wet July of this year. The marvel is that more did not suffer.

Of Plums and Damsons, which are a more remarkable stock than Pears, there is a larger number grown than even of the Apple, the stock being about 175,000; in fact the Plum culture is one of the features of the nursery, and it is to be hoped that ere long a number of utterly worthless varieties which are cultivated in all parts of the country, so that when a good Plum season comes they are a complete glut, and, as was the case three years ago, rot by bushels on the trees, as no one would take the trouble of picking them, will be discarded. There were large quantities of Victorias and Rivers' Prolific, while amongst Damsons that most prolific variety the Farleigh Prolific, Kent Cluster, or Crittenden, is cultivated to the extent of 40,000. Anyone who wants to grow Damsons ought to grow this, for not only is the tree hardy and prolific, but the fruit has that true rough Damson flavour which other sorts are wanting in, approaching as they do in size and flavour more to Plums. As might be expected in a county so famous for its Cherries, there is a supply here ready to meet the demand, the Bigarreau being especially sought after. Nothing can be finer than the clean healthy looking orchard trees of these fine rare Cherries, and they are, moreover, true to name.

Need I say that the utmost courtesy and kindness was shown to us? All who know Mr. Bunyard will be sure of this. I know this is but one of many nurseries where fruit trees are grown for sale, and it is a comfort to know that if persons wish to embark in fruit growing they can do so under the happiest auspices.—D., Deal.

EVENTS OF THE WEEK.—The Chrysanthemum shows still constitute the principal horticultural events, but another week will nearly bring them to a close. To-day, Thursday, there are shows at Brixton, Reading, Pembroke, Stroud, Wimbledon, Lindfield, and several other places. On Friday the National Chrysanthemum Society's provincial show will be opened at Sheffield and continue on the Saturday. It will no doubt attract a large number of visitors, and most of those travelling from London will leave St. Pancras by the 5.40 train on Thursday evening. On Saturday a Show is announced at Derby. On Tuesday, the 20th inst., the Liverpool Show will be held, Birmingham and Rugby on Wednesday, November 21st, and Hull on Thursday, November 22nd. It may be noted that the Borough of Hanley Show takes place on the 20th and 21st, and is followed by a show at Newcastle, which is only about two miles distant, on the 22nd and 23rd. Messrs. Small & Co. announce sales of bulbs and forcing roots on November 19th, 21st and 23rd.

— LEEDS HORTICULTURAL SOCIETY.—In the absence of any suitable place for holding the usual summer Show this year the Committee respectfully ask subscribers to transfer their subscriptions to the exhibition of Chrysanthemums to be held on the 21st and 22nd inst., when from the promises of the principal exhibitors the Committee feel justified in announcing that the Exhibition will be worthy of extended support.

— WE are informed that the Trustees of the British Museum have appointed MR. ALFRED BARTON RENDLE, late Assistant Demonstrator of Botany, Cambridge, an assistant in the Department of Botany at the Natural History Museum, in the vacancy occasioned by Mr. H. N. Ridley's taking the office of Director of the Botanical Gardens at Singapore.

— MR. J. HAM sends the following note on the ANOMALIES OF THE SEASON IN INSECT LIFE:—"It has been most singular as regards some of our commonest insects. The caterpillar plague will long be remembered; nothing approaching it do I remember. The winter moths are coming out in swarms as a natural sequence after so many caterpillars. On taking a light to an Apple tree that has been blighted in the summer, the female moths—which are wingless, or the wings undeveloped, so that they might cause them to be mistaken for spiders—may now be seen running about the trunk seeking a snug place to

lay their eggs, which will hatch out in the spring. No time should be lost in dressing trees to prevent the moths running up. In addition to the caterpillar plague we have had to contend with a ravenous host of earwigs. On one occasion only I killed, as nearly as I could tell without actually counting every one, 2750 in going round my garden and a small orchard. Against this as a set-off we have not had a wasp of any of the species which eat fruit and rob bees, and during the whole summer in all my walks I have only met with two solitary worker wasps. It will be curious to see if the race is actually extinct. It must take years to produce or establish these insects again if there are any left in other districts. Another curious fact is that there are no daddy long-legs this year, although there were grubs in the summer, as I know the starlings brought them for their young in the nests; yet in the fields and gardens no insects appear to have been hatched out. One other injurious insect (in the grub state) has been very scarce, the cockchafer or locusts as they are usually called. I cannot remember seeing half a dozen during the summer."

— LORD PALMERSTON PELARGONIUM. — This old Nosegay variety has flowered more freely with me than any other during the past summer, wet and cold as it has been. The colour is rosy red. Vesuvius has scarcely flowered at all; West Brighton Gem, Henry Jacoby and others have grown very strongly, but have produced few flowers.—G. C.

— MR. F. GEESON of Midhurst writes:—"Mr. A. Pettigrew, on page 429, speaks of PETROLEUM FOR PEAR SCALE. As we have a great quantity of the pest, I would be glad to know at what strength it should be applied. I tried last winter 1 oz. to the gallon of water, and there are as many pests this winter as last. If Mr. Pettigrew would state the proportion of oil to the gallon he finds effectual and safe, I shall be glad."

— WE are informed that the TEDDINGTON CHRYSANTHEMUM SHOW was highly successful in all respects, the cut blooms being excellent and numerous. Mr. G. A. Bishop, The Grove Gardens, Teddington, won the principal prize, a silver cup, W. Furze, Esq. (gardener, Mr. Coombs) with Messrs. Munro, Bates, Allen, and Davies also exhibiting well. Mr. D. Anderson, the Hon. Secretary, has worked hard in the interest of the Society.

— WE regret to hear that ALDERMAN THOMAS GRAY, OF MORPETH, died on the 13th inst. The deceased gentleman was an ardent supporter of horticulture in the North of England, and took an especial interest in the Newcastle-on-Tyne Society, of which he was Treasurer for some time. He was widely known, and much respected by all who had the pleasure of knowing him, and a correspondent writes that he was "an enthusiast in gardening, a most genial friend, and an excellent business man."

— A GARDENER recently staying at SOUTHPORT IN LANCASHIRE sends the three following notes—"The small gardens about Southport are much better kept than is the case in the neighbourhood of many seaside towns. Evidently great taste and care have been exercised in planting them. Too often carelessness is the rule in such gardens, dead and dying trees and shrubs telling too plainly of the mistakes that have been made; but here evergreen Privet, Hollies, Euonymus, Aucubas, and such seaside plants have been planted and flourish amazingly. Poplars and Elms have been freely planted, and are doing well."

— "THE foreshore has been greatly improved during the past few years. A large portion of the beach has been converted into delightful grounds with walks freely interspersed amongst the grass, which is in capital condition. This is made cheerful during the summer by the introduction of flower beds of the ordinary bedding type, with annuals and perennials planted in the borders. The sea is a long way from the town, and to obviate this a large lake has been formed in front of these grounds. To carry out the same arrangements on the other side of the pier would be money well spent, and would undoubtedly prove profitable to the town."

— "THE BOTANIC GARDEN AT CHURCHTOWN has been beautifully laid out, and has been gay with annuals and hardy flowering plants in the past season. Very few of the ordinary tender bedding plants are employed, and if this were done it would be impossible to have produced with them such a diversified and charming effect as has been the case. The grounds are well kept and varied with cool shady walks, Rose beds, and borders, water-loving plants and Ferns. Every bed and border where sun and light can reach is gay with flowers during the summer, for there has been ample room left at the front of all the shrubs for this purpose."

— LILIUMS IN PARTIAL SHADE. — Liliiums unquestionably like partial shade. When fully exposed to the sun they gradually dwindle away, but in the shade, or where they are protected from direct sunshine, they increase in numbers and strength. We have a good number of Liliium tigrinum superbum, and those shaded by trees were the strongest, and have produced the greatest number of flowers on each spike. Although the trees are growing close to them, they did not appear to suffer last year by drought. Several other Liliiums have also behaved in the same way.—W. B. L.

— THE FIG HARVEST.—The Fig harvest this year has been good, while last year it was very much below the average. The whole crop, that practically supplies Europe and America and a great part of Asia, is gathered from a strangely limited acreage. The average yield is about 25,000,000 lbs. The yield of 1887 was much less. This year it will be a little over average. America is largely increasing her demands, and the London consumption grows more and more important every year. It is the "Lacoum" Figs that are sent in greatest quantity across the Atlantic. The whole Fig crop is gathered off very classic ground. The gardens lie along the valley of the Meander, and especially round the ruins of Ephesus. Turks and Christians work side by side, and in perfect amity.—(Daily Paper).

— WRITING about PHLOXES, a northern correspondent says:—"These have been beautiful during the past season; the wet weather appeared to suit them, for they have never been healthier or produced larger trusses with us. Virgo Marie is a splendid pure white variety, and just coming into flower. Enfant du Rhone is very distinct, with its large amaranth reddish scarlet flowers. It is a grand companion to the one named above for late flowering. The last will flower freely until the end of October if planted in different aspects. Few plants are more effective planted in small groups about the pleasure grounds; if they are dashed by heavy rains, the flowers open so quickly that a few hours of bright sunshine renders them highly attractive."

— THE same correspondent remarks that "RUDBECKIA NEWMANNI is not very attractive when planted on the dotted system in mixed herbaceous borders, but it is one of the most attractive plants in the garden when planted in moderate large masses. When six or twelve plants are planted about a foot apart and allowed to spread until they are well established, they are conspicuous either at the front of shrubs or surrounded with annuals or other flowering plants."

— GROS COLMAN GRAPE IN POT.—When recently visiting Mr. Butts at Leigham Court Gardens, Streatham, I was much impressed with the value of this fine-looking Grape as a pot Vine. Mr. Butts had a Vine that had been in a very large pot two seasons; this season when I saw it, the Vine had eight good-sized bunches. It was growing in a Black Hamburgh house. The bunches were well filled, as black as jet, and from 1 lb. to 1½ lb. in weight. It is the improved flavour that I wish to note. Mr. Butts gave me a few berries to taste, and in comparison with some that were growing on a Vine planted out here it was much superior. In fact, I do not remember ever to have tasted it so good before at this season. It may be worth asking those who have not the accommodation to grow it planted out, but would like to have a few bunches, to grow a few Vines of it in a pot in a house that may be wanted for other purposes during the winter. When those were ripe they could be lifted into a warm dry Muscat or other similar house till wanted. While speaking of Leigham Court I may remark that I also noted good bunches of Muscats, the most useful West's St. Peter's and many others still hanging.—WANDERER.

NARROW VINE BORDERS.

THIS subject has been receiving some attention lately, but no more than it deserves, for if less expensive borders will give equally good results with those of the usual description, the fact cannot be too widely known. When individual cases are cited as instances of success or failure, erroneous notions are apt to be drawn from them which were never intended by the writer. It is well that success under difficulties should be recorded, whether it is the production of good Grapes in ordinary garden soil, or in borders much within the usual limits, or any other result which shows that the grower's heart was in his work. This acts as a stimulus to others. In like manner the chronicling of a failure comes as a warning. No gardener of experience can doubt that good Grapes can be grown well for a few years in comparatively narrow borders, but where the doubt will arise is respecting the length of period in which they will continue satisfactory. That this is generally believed in is shown by the manner that borders are usually made, only soil enough for a few years being placed in first, and other soil added as the roots show they require it. It would be interesting to

know how long Vines have proved satisfactory in narrow borders, and the treatment they received. Of course the definition of a narrow border will vary with individuals, but it may, I suppose, be understood to mean in a general way small in proportion to the Vines which derive their support chiefly from it.

My first experience with narrow borders was when a junior in an establishment where Vines were grown well. Pot Vines had previously been grown for an early supply with the uncertain result they usually produce. The bed in which the pots were placed was of fair dimensions; then a border was made and canes planted as soon as the pots could be removed. As they were forced annually when established their life was but short, and after several years, when signs of weakness were showing, they had to make way for others. Now for such a purpose as this a narrow border is in every respect preferable to one of the orthodox description.

At a later period I had charge of a vinery where from force of circumstances the border was what was generally considered too narrow, and yet the Vines for about four years bore excellent crops of good Grapes. After that time they began to colour indifferently, although the bunches were of good size and the berries quite up to the average. It seemed as if they had nearly exhausted the soil, and the feeding to which they were necessarily subjected had only the effect of carrying them on to a certain stage, and failing when the colouring began. Even top-dressing a narrow border has not the same influence on the Vines that it has on a more proportionate one, the crowded condition of the roots making it more difficult for all to get a share of its virtues.

My experience shows that for permanent Vines narrow borders are not advisable where borders in proportionate size to the vinery can be made, but, as several correspondents have so ably demonstrated, plenty of porous material in the soil is a matter of great importance whatever the size of the border.—M. D.

THE NATIONAL AURICULA AND THE NATIONAL CARNATION AND PICOTEE SOCIETIES.

(SOUTHERN SECTIONS.)

As the writer of the report of the annual meeting of the above Society, held on October 23rd, which appeared in the *Journal of Horticulture* (page 390), I take exception to Mr. Douglas's statement that it was an inaccurate one. It was a fair, honest, and independent report, and my simple aim was to bring before the notice of florists the fact of the existence of societies that have of late appeared to hide their light under a bushel, and by giving publicity to the fact of their existence seek to increase their usefulness. As I am not in any way responsible for the "adverse criticisms" founded upon these reports, it is not necessary for me to refer to them. The main point in Mr. Douglas's contention is, not that I was guilty of an inaccuracy, but of an omission—namely, that I said nothing about application being made to the Royal Horticultural Society. I was silent about it because I heard nothing respecting it of a definite character. The place for holding next year's Exhibition of the National Auricula Society was certainly discussed, and a general condemnation of the Drill Hall at Westminster indulged in. Those who were at the Exhibition held there in April last will remember it was so dark within that the colours of the flowers could not be determined with accuracy. It was assumed that as the R.H.S. gave the Society nothing in 1888 they were hardly likely to do so in 1889, therefore it was agreed that Messrs. D'Ombra and Hibberd should approach the Crystal Palace Company to see if terms could be obtained from that quarter. I objected to going to the Crystal Palace on the ground of its distance from London, and I said that supposing the Council of the Royal Horticultural Society were to agree to carry their meetings to Chiswick, that it would be better to hold the Show there without a subsidy than at the Crystal Palace with one; but I heard nothing about approaching the Council of the R.H.S., and, indeed, that seems to be an afterthought on the part of Mr. Douglas. Mr. Douglas appears to think that he as the Secretary to these Societies should have, and indeed possesses, the exclusive right to send reports of their proceedings to the gardening papers, but I hold that the annual meetings of these Societies are as interesting to horticulturists as that, for instance, of the Royal Horticultural Society. They are Societies appealing for public support, and it is only fair the public should be made acquainted with their proceedings. I object altogether to Mr. Douglas regarding these Societies as his sole property. Their existence is known to comparatively few, and for want of the knowledge they do exist, but this knowledge should be conveyed by means of impartial and independent reports, and not by those prepared by their officials, such reports being too often coloured according to circumstances.—RICHARD DEAN, *Ealing, W.*

CANKER IN FRUIT TREES.

REFERRING to some comments on my paper on canker by two of your correspondents, I think Mr. Kruse may be led astray if he relies on analysis of his soil as a guide in estimating the ingredients of the manure required to supply its deficiencies. The father of modern agriculture, Liebig, says "Analysis gives but rarely a correct standard by which to measure the fertility of different soils;" and Ville, "The most laborious analysis is not able to throw light upon the most vital and essential questions of practical agriculture." The reason for this is very

simple. Although the chemist can accurately determine the several ingredients of a soil, he cannot distinguish between such as are soluble and available by the plant and those which are insoluble, and consequently inert; therefore in attempting to cure canker the application of a complete manure, containing all which may be required for perfect growth, is more likely to produce satisfactory results. It is extremely improbable that the iron in Mr. Kruse's soil is a cause of canker. The 3.38 per cent. given in Dr. Voelcker's analysis is far from an excessive quantity. Some of the most fertile soils known contain three times as much of the peroxide. Nor need he have any fear of the acid in superphosphate producing injurious effects, but its use may involve a question of economy, as recent experiments seem to prove that undissolved phosphates are equally beneficial.

Some misapprehension exists of the object of my paper. It was not intended in any way to describe the nature of the disease so well known as canker, but to suggest what are the circumstances under which it may make its attacks, and the means by which these may be warded off, and possibly the disease cured.

It is not improbable that the disease itself may be due to the fungus referred to by Mr. Fraser in his paper on "The Enemies of the Apple and Pear," as *Nectria ditissima*—it is so stated in De Bary's book on fungi, Oxford, 1887, on the authority of two German naturalists, R. Hartig and R. Goethe—but while it would be absurd without sufficient reason to question the conclusions of such distinguished authorities, there need be less hesitation in expressing a doubt as to the relation of *Acari* to this disease. Some of these little arachnoids, notably the red spider, are the most troublesome pests with which the gardener has to contend, but others are not enemies. The scarlet mite (*Trombidium holosericeum*), to which I suppose "J. R. S. C." refers, being carnivorous is probably beneficial, and has about as much to do with canker as its much-abused relative has with the disease of the *Eucharis*.

Our knowledge of the animal and vegetable parasites affecting plants is yet in its infancy, and the injury done by them is, I believe, increasing. Patient observation may in time enable us to work out the life history of these terrible pests and discover means of averting their attacks. In the meantime we cannot do better than encourage healthy growth. It is patent to the most careless observer that both animals and plants when well nourished are not so subject to the attacks of parasites as those in ill condition. Topical applications of insecticides and germicides may give temporary relief, but the good gardener has occasion to use them but rarely.—EDMUND TONKS.

I HAVE read all the articles in the *Journal* on this subject with interest, and I did not intend to intrude with any remarks until I noticed my name mentioned by your correspondent, "J. R. S. C." I am very pleased to see that the subject has received so much attention at the late Conference. It would be presumption on my part to follow these scientific papers with my poor abilities. A member of our Amateur Gardeners' Society was once asked to give a paper on a subject with which it was known he was familiar as a practical grower, and his answer was that he could not, and in his simple and unaffected way said he knew nothing about it, "only from experience." Another was asked to give us his experience on "hult-growing," especially Hyacinths, as he was well known to have been a successful grower. His reply was, I can give it in a few words, it was to this effect, "Fill your pot three parts full of soil, place your bulb on it, and then fill up with soil, and water occasionally." My experience of canker and its cure remains so far about as short. If I get rid of the live stock or *acari* my trees remain healthy, notwithstanding the soil, climate, weather, drainage, and bad sorts for canker, including Wellington and Ribston Pippin. I should like to see a piece of the cankered wood referred to on page 407, "and others near cankered with no insects upon them." I am afraid I am too much like Thomas of old.—J. HAM.

ROYAL HORTICULTURAL SOCIETY.

THE usual fortnightly Committee meetings were held in the Drill Hall, Westminster, on November 13th, but the duties of the Committee were extremely light. One side of the large hall sufficed for the exhibits.

FRUIT COMMITTEE.—H. J. Veitch, Esq., in the chair. Present: Messrs. Crowley, Cummins, Blackmore, Willard, J. Smith, Denning, Cheal, P. Barr, and Marshall. Mr. E. H. Woodall, St. Michael's House, Scarborough, exhibited a dish of Grapes under the name of Mrs. Clarke, described as a seedling from Gros Colman and as ripening earlier and colouring more freely than the parent. The bunch sent was small and not well coloured. A seedling Apple unnamed and undescribed was shown by Mr. Kent, Denver, Downham Market. Mr. W. Roupell, Harvey Lodge, Roupell Park, London, S.W., staged a collection of fifty-seven varieties of Apples, comprising good examples of Peasgood's Nonesuch, The Queen, Ecklinville Seedling, Stirling Castle, and Loddington. A bronze Banksian medal was awarded. He also showed a basket of Pears, comprising two fruits of Pitmaston Duchess weighing respectively 16 and 15 ozs. from trees grown in pots out of doors; two fruits of Baltet Père and Louise Bonne, both from trees on the Quince stock, were also exhibited. A. Lane, Esq., Mileham, Leigham Court Road, Streatham (gardener, Mr. Thornton), also exhibited a collection of Apples. A collection of Onions came from the Society's garden, also a dish of *Stachys tuberifera*, and a few examples of Beetroot. Mr. Willard, The Gardens, Holly Lodge, Highgate, exhibited specimens of a new vegetable described as *Asparagus Chicory*, and stated to be suitable

as blanching for salad or cooking green as a vegetable. Mr. Tozer, Leamington, had a dish of a seedling Potato. A first-class certificate was awarded to Messrs. Carter & Co. for tubers of *Stachys tuberifera*, cooked specimens also being sent. These somewhat resemble Artichokes in flavour, and with the proper accessories would be by no means bad. A certificate was also awarded to Onion Southport Red Globe. This was exhibited in the collection from Chiswick referred to above, and was under trial for Messrs. Veitch & Sons. It is a globe-shaped variety, of medium size, and very highly coloured.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. Present:—Messrs. J. Laing, Wynne, Dominy, Pollett, O'Brien, Walker, Duffield, Herbst, Noble, Pileher, Ballantine and Wilks.

Messrs. James Veitch & Sons exhibited a box of hybrid greenhouse Rhododendrons, for which a vote of thanks was awarded. The most noticeable of the varieties was Primrose, a beautiful canary coloured bloom of admirable form; it is a seedling from Teysmanni. A form of the multicolor type named Hippolyte was also noteworthy. The truss, which is of close and handsome form, bore sixteen flowers of a rich scarlet crimson hue. The other varieties comprised hybrids of the javanicum group. Mr. Herrin, The Gardens, Dropmore, Maidenhead, exhibited a pair of fine cones of *Pinus Lambertiana*, for which he was accorded a vote of thanks. A. H. Smee, Esq., The Grange, Hackbridge (gardener, Mr. Cummins) exhibited *Disa coelestis* (? graminifolia), and R. D. Knox, Esq., Caversham, Reading (gardener, Mr. Lawrence), showed *Oncidium cornigerum*. Mr. Herrin showed some *Chrysanthemum* blooms with smaller clustering around them, under the name of "Hen and Chickens."

A fine group of *Cyclamens* came from Mr. Warren, Worton Gardens, Isleworth, and a silver Banksian medal was deservedly awarded. The plants numbered upwards of 200, and formed a pleasant feature of an otherwise dull gathering. The plants were healthy and well flowered. First-class certificates were awarded to the following:—

Chrysanthemum Mr. Garnar.—This was exhibited by Mr. Stevens, of Putney, and has been several times previously honoured and described. It is a Japanese of a bronzy yellow hue, with narrow fluted florets.

Chrysanthemum Avalanche.—This was also shown by Mr. Stevens, and is illustrated and described in another column. The blooms shown on the present occasion were distinguished by the breadth of floret and singular purity of hue which are the characteristics of this charming variety. The blooms, however, were small.

Lelia Victoria.—This was exhibited by Baron Schröder, The Dell, Egham (gardener, Mr. Ballantyne), and is a hybrid between *L. crispa* and *L. Domini*. The flower resembles *L. crispa* in the petals and sepals, and is deliciously fragrant. The sepals are much recurved, and give the flower somewhat too light an appearance, but the lip was magnificent, being deeply coloured with rich rosy purple from the tip to the throat. This grand variety aroused considerable interest amongst the orchidists present.

SPECIAL MEETING.

Subsequent to the Committee meetings at the Drill Hall a special meeting of the Fellows and the public was held at the Council rooms, 111, Victoria Street, Westminster, to consider the question of where to hold the meetings of the Society in the future. The chair was taken by the Rev. W. Wilks. Dr. Masters was of opinion that much more might be done with Chiswick, and in this he was supported by Mr. Shirley Hibberd. Subsequently Dr. Masters proposed the following resolution: "That the Council be requested to hold a certain number of meetings in the summer and autumn at Chiswick." This was supported by Mr. Hibberd, and carried with one dissentient. The Chairman stated that those who were unable to attend the meeting had been invited to state their views in writing, with a view to their consideration by the Council. Amongst those who had acted upon this suggestion were Messrs. Ware, Cannell, Cypher, Rumsey, Miles, Ryder, Mayer, Barnes, Crowley, W. S. Walker, Henwood, Arbutnot, Pragnell, Phillips, Baines, Dean, Sutton, Ross, Holmes, Wright, &c. The general opinion appeared to be that Chiswick would not be a suitable place to hold the exhibitions of the Society, being less easily accessible than a central place in London. Several spoke in favour of a fewer number of exhibitions, and Mr. Cheal suggested that they should be divided between London and Chiswick. Messrs. Bunyard and Pearson expressed a hope that a later hour could be selected for the meetings of the Committee. Mr. G. Paul said that he did not consider the Drill Hall a failure, there had been larger attendance there than at South Kensington before the Great Exhibition years. Speaking as a tradesman he had found it to answer well. Opinions as to the suitability of the Drill Hall were then invited by the Chairman, and after some discussion it was proposed by Mr. May and seconded by Mr. Bunyard that the Council be advised to retain the Drill Hall for another twelve months, and on a show of hands being taken this was declared carried by a majority of twenty to four. The proceedings then terminated.

HORTICULTURE IN MALTA.

THE "Kew Bulletin" for the current month continues the interesting reports on colonial fruit. Amongst them are the following notes on Malta and its wild fruits, an elaborate account of the cultivated fruits in the island, extending over six pages, being added.

The inquiry into the fruits of Malta was entrusted by the Government to a special board. For this board the following exhaustive

report has been prepared by Professor Gavino Gulia, M.D., Director of the Botanic Gardens:—

The Maltese islands have been from time immemorial celebrated for their fertility. The spikes of corn on ancient Maltese coins denote the fecundity of Malta, the agricultural produce of which has often been praised by Roman writers. Rich and very productive plantations which covered this country were destroyed by the Saracens who took possession of these islands (A.D. 870—1090). It was in the fifteenth century that our countrymen began to repair the great damage thus caused by these enemies of Christendom and civilisation. Unluckily, afterwards the cultivation of Cotton and Wheat, and in modern times that of Potatoes, which to our husbandmen seemed more profitable, was the cause of their putting aside the planting of trees. The extensive plantations were no more cared for, the trees were felled for timber to make room for other economic products, a fact which is greatly to be regretted, for, owing to its excellent climate and fertile soil, trees and shrubs of different kinds grow in Malta wonderfully and produce fruit, which being of an exquisite sort, would well repay exportation. It is desirable that the Agrarian Society of Malta and the wealthy proprietors of lands should do their utmost to have these islands once more covered with productive plantations, giving preference to the Olive, the Almond, the Vine, and Orange trees.

The long-felt need of water supply in rural districts has lately, fortunately, been a subject of careful research. The water supply of these islands is derived from rainfall, part of which is directly absorbed by plants, part is re-evaporated, part runs into the sea through numerous ravines, and part sinks into the soil and occupies natural reservoirs, or runs between the strata that form the geological structure of the Maltese group. By digging deep wells a considerable amount of water has already been obtained. By the laws lately enacted our ground tillers will no more depend simply on the rainfall, as a reasonable supply of water will be pretty equally distributed to all parts of the island. In a place like Malta, subject to droughts from periodical want of rain, tanks are indispensable to the agriculturist; it would therefore be advisable to force, by law, landlords to dig a tank in each field, the dimensions of which to be proportionate to the extension of the field itself. With the view of encouraging agriculture, prizes for the best plantations should be awarded to farmers; and whilst an easy way of obtaining young trees is afforded them, the expense of obtaining water for irrigation should be as moderate as possible.

The art of manuring is very little understood by our farmer, who chiefly uses rotten animal and vegetable manures after having exhaled their best constituent parts whilst lying in a corner of his field. He knows nothing of liquid manure, "which," as Professor Lindley remarks, "works the wonder, and operates like the overflow of the Nile or the Indus." The large quantity of nightsoil, which is now lost in the sea, would become a most valuable manure to our gardeners were they taught how to employ it properly. Owing to the unchanging habits of our country people, the Maltese farmer does not differ greatly from his ancestors. Very little, if any, novelty has been introduced into the old farming customs of Malta. Owing to the want of sound knowledge of horticulture and of proper agricultural implements, the work of our farmers is laborious, tedious, expensive, and often unsuccessful. As a modern writer remarks, "Farming in Malta and Gozo is a battle and victory of labour. The 144 square miles comprised within the insular area are partly barren rock and in many respects a geographical riddle. Cultivation has asserted its sway over 54,716 acres, the remainder being sterile rocks." It is to be hoped that a large portion of the waste open spaces some day or other will be brought under cultivation, that the primitive implements of agriculture still in use will be superseded by proper machinery suitable for our soil, and that, as books for our farmers are useless, lectures on horticulture will be given them in each casal, with the view of teaching them how to improve their old methods of cultivation and lead them to the discovery of better modes. It would be then possible to introduce and largely cultivate many exotic trees and shrubs, bearing excellent fruit both for the home market and for exportation; and to improve at the same time the products of those species which are now more or less successfully grown.

Wild Fruits.—Under this term we include the *Rubus discolor*, or common Bramble, called Ghollick by the Maltese, plentiful both in Malta and Gozo. The small acid drupes are grateful to most palates. Our ancestors used to make of them jams, tarts, and a syrup which, being sub-acid and cooling, was recommended to allay the heat and thirst of patients suffering from fever. The Fig tree, *Ficus carica* (tin salvagg), is also a native of these islands. The wild variety produces small and delicate fruits. As many varieties of this tree have been introduced to Malta from abroad, we th n't proper to include them among the cultivated species. Of the Olive, the wild variety of which is also a native of these islands, we shall speak hereafter, and also of the Pear, a variety of which grows wild in several gullies of Malta. Also indigenous is the Azarole Hawthorn, *Crataegus azarolus*, called Ghanzalur by the Maltese, the fruit of which, yellow or red, has an agreeable taste, and is by some much esteemed for making tarts. The fruit of the common Hawthorn, *Crataegus monogyna*, is very small, and only eaten by children and birds. It is known under the name of Zgharun. The *Mespilus germanica*, which used to abound in several ravines, especially in the neighbourhood of the Boschetto, belongs now only to the flora of Gozo, where it grows seemingly wild among bushes. It is called Pommel lip. The fruit of the wild variety is middle-sized and worthless. The Medlar is cultivated in some gardens, where it produces a fruit which, like that of the *Sorbus domestica*, is eaten in a state of incipient decay.

Punica Granatum and *Ceratonis asiliqua* belong to the flora of these islands, so does *Olea europæa*.

We think that *Ceratonis* should be more extensively cultivated for the sake of the abundant Carobs it produces, called *Harrub*, which are eaten by the poorer classes, especially in times of dearth, and form a nourishing food for all kinds of cattle. A very considerable quantity is consumed yearly by horses. It is, therefore, largely imported from Sicily and Cyprus, the quantity of pods produced in Malta being insufficient for this purpose. The Malta Carobs are sold from 2s. 6d. to 5s. per cwt. The Carob tree does not require any particular culture; it is slow in growing and lives for many ages, especially if care be taken to screen it from the cold northern winds which visit us during winter, by planting the young trees on the northern sides of the ravines.

THE BRITISH FRUIT GROWERS' ASSOCIATION.

A MEETING of the above Association was held in the Balloon Room, Royal Aquarium, on Thursday last, November 8th, to discuss the subject of railway rates in relation to fruit transit. Mr. T. F. Rivers took the chair at 5 P.M., and amongst those present were Mr. W. Roupell, Brixton; Mr. Albert Bath, Sevenoaks; Mr. J. Laing, Forest Hill; Mr. R. Ivatt, Cambridge; Mr. R. Dean, Ealing; Mr. J. Cheal, Crawley; Mr. C. J. Goldsmith, Beckenham; Mr. E. Butts, Streatham; Mr. A. Dean, Bedford; and the Hon. Secs., Messrs. L. Castle and W. Earley. In the course of a few introductory remarks the Chairman said—I have to congratulate this Association on the very encouraging success which has attended its formation. We have received greater support and sympathy than we expected, and I think we may say that the Association has become an established fact. We have succeeded in drawing public attention to the necessity of thoroughly examining the possible outcome of the decadence of industrial fruit-growing in this country, and I hope of arresting the serious loss which would undoubtedly occur if measures were not taken to arrest such loss before the evil had gone too far to mend. This Association will not have been formed in vain if it can succeed in attracting the serious attention of cultivators to the best means and methods by which the country can hold its own in the competition with which it is threatened, and the objects of our Society are to obtain the best possible information from fruit growers in different parts of the country, and to distribute this information as widely as possible. With this end in view we propose in the ensuing year to hold meetings in the provincial districts to invite the co-operation of all who are willing to help us in the good work by reading papers and assembling to discuss matters which are of vital importance to the particular industry. Our meetings will be held on the understanding that they will be entirely non-political, and this salutary abstinence will, I hope, meet with the hearty approval of all who join us. We intend to deal with matters of important interest in a thoroughly impartial spirit. One of the important points is the cost of the conveyance of fruit, and we shall be glad if we can, by obtaining information, enable growers, handicapped by distance from the centres of distribution, to compete with those more happily situated. We trust that we shall be able to obtain by reports from competent persons sufficient knowledge on this head to submit our case to the Board of Trade. We are not accustomed in England to make a grievance, but to examine and endeavour to remove an existing one. In this particular case there are good grounds for believing that the cost of the transport of fruit is much greater than it need be, and that this cost presses heavily on one of our native industries. There can, however, be no doubt that the question will be fairly dealt with. I must remind those who make the reports that the facts must be accurate, and that a case which is to be submitted to the Board of Trade must be very clear and distinct.

We also hope by inquiry and discussion to raise the standard of quality of fruits sent to market, and as planting is likely to be carried on for some years on a more extensive scale than has hitherto been known, any information as to the relative value of sorts in different districts will be of very great importance to the planter, and it will, I hope, be one of the aims and objects of the Society to classify and determine as far as possible the suitability of sorts of fruits to different localities; the fewer sorts the better, both for the fruit tree grower and the planter. It is, I think, known to many that a very decided liking is exhibited by certain fruits to particular districts. I may instance the Winesour Plum in Yorkshire, the Apple orchards of Herefordshire and Devonshire, the Bullaces of East Anglia, and in my own district the singular success of the Early Prolific Plum. A Society which can visit the different fruit-growing districts will be able to gather more facts than a Society which is fixed permanently in any one locality, and will, I imagine, much extend its sphere of usefulness.

Several letters were read from members of the Association and others interested in the subject, and it appeared that those who lived sufficiently near all sent their fruit by road as cheaper and safer, one stating that it would be to his interest if all the railway rates were increased. The majority, however, at a distance from towns condemned the present charges strongly. Mr. Watkins of Hereford remarking that the present rates are amongst the greatest hindrances to the extension of fruit cultivation. Mr. J. Udale, Tamworth, wrote—"Railway rates for the transit of fruit and vegetables under some circumstances are quite prohibitive. Twelve months ago I was in the habit of sending all classes of fruit to two fruiterers in Birmingham. Choice fruit was sent by passenger train, coarse fruit and vegetables by goods train, thinking it would be much cheaper. However, after one or two consignments

had been delivered at the ordinary goods rate, I received notice from my customer—whom I have known for many years, and is a strictly honest and truthful man—that the railway company had a higher tariff for fruit and vegetables, and that they demanded extra payment of either 1s. 3d. or 1s. 6d. on previous payments for the same weight of the same class of goods in the same hamper. This additional charge, in conjunction with a rate upon returned empties, caused me to cease sending such goods to Birmingham, and I dispose of them nearer home. This excessive charge by the railway company causes a direct loss to four classes of the community:—First, the grower; second, the railway companies themselves; third, the fruiterer; fourth, the public. My experience is, that the railway rates are prohibitive of the rapid transport and wider distribution of all classes of garden produce except fruit and flowers of the highest quality, beyond a distance of twenty miles; and I have long been of opinion that the time had come when it was desirable that growers should combine for the purposes of dealing with railway rates, selecting the most suitable markets, and disposing of their own produce, if possible, direct to the consumer."

From Mr. W. E. Bear a suggestive letter was received in which he said—"I am sorry that I have too much in hand for the next fortnight to help your useful Association by preparing and reading a paper on railway rates. It seems to me that the only really important thing for your Association to do in this connection, is to form a Parliamentary Committee, and to get the Association recognised as a body entitled to be represented before the Board of Trade. All members who have real grievances should send details to the Committee, and those that prove on examination to be valid should be brought before the Board of Trade. It is of no use to read a paper showing that rates on fruit are too high; everybody knows that. The time has come to get such rates reduced."

Mr. Albert Bath said he was not prepared to treat the subject fully, but he had made some careful comparisons between the rates per ton for fruit conveyed by rail from different stations at an equal distance from London, and he showed by a series of figures the extraordinary disproportion that existed on some lines. He contended that a system of equalisation was needed in the interest of growers who had to send their fruit long distances.

Mr. R. Dean followed with some facts and figures relating to the irregularities of railway charges, showing how the foreign preferential rates press very heavily on the home producer, the difference in a railway rate often meaning the whole of the profit. It was stated that English Potatoes and fruit cost 23s. 4d. per ton to bring from Selling to London, yet foreign produce of the same character were brought to London via Selling for 20s. per ton.

Mr. R. Ivatt, Mr. J. Cheal, and Mr. A. Dean also gave many statements of a similar character, but Mr. Figgures of the Railway Clearing Office remarked that the railway companies were mostly willing to make any reasonable concessions, and that there was a danger if rates were much decreased it would have a tendency to flood some markets, with a consequent reduction in prices to the producers. He thought the best plan was to encourage people to send their goods to the nearest markets. In the course of a prolonged discussion many interesting and important facts were elicited, and the business of the meeting was concluded by a resolution, proposed by Mr. Ivatt and seconded by Mr. Roupell, to the effect "that the Executive Committee of the British Fruit Growers' Association be requested to collect all available information on the subject of railway rates in fruit transit and distribution, to enter into communication for this object with the Railway and Canal Traders' Association, and to submit the results in the form of a report at the earliest convenient meeting."

THE CHRYSANTHEMUM CENTENARY.

As the result of a letter sent by Mr. W. Holmes to one of the daily papers, some comments upon which have already appeared in this Journal, a meeting of the Judges at the Crystal Palace Chrysanthemum Show was by permission of the Secretary, Mr. Gardiner, held in the Board Room on Friday afternoon last. Mr. E. Sanderson occupied the chair, those present being Messrs. W. Holmes, R. Ballantine, J. Laing, J. Douglas, G. Gordon, J. Douglas, L. Castle, R. Dean, and W. G. Head. After some discussion respecting the desirability of celebrating the centenary, concerning which there was not the slightest difference of opinion, it was proposed by Mr. Laing and seconded by Mr. Earley—"That considering the year 1889 is the centenary of the introduction of the Chinese Chrysanthemum into Europe, it is advisable that the National Chrysanthemum Society be requested to prepare a scheme for the proper celebration of the event." This was adopted unanimously, and several suggestions were made as to the best way in which such a celebration could be best effected, one point being strongly pressed—*i.e.*, that it was desirable as large a collection of plants as possible should be grown with a view to their careful comparison and the determination of synonyms and the correction of nomenclature.

JAPANESE CHRYSANTHEMUM AVALANCHE.

THIS remarkably handsome pure white Japanese variety was brought into notice by Messrs. H. Cannell & Sons, Swanley, last year. Mr. E. Molyneux secured plants, and some of the finest blooms yet shown have been from the Swanmore Park garden, one of these being represented in the illustration (fig. 51). That its merits quickly became recognised by cultivators is proved by the fact that it obtained a place in the National Society's catalogue select list. The blooms are pure white, large, full and round, the florets very substantial, straight, or slightly drooping

many growers to undertake its culture. Most of the varieties Messrs. H. Cannell & Sons sent out last year have obtained a good position on the boards, but that best and most frequently shown is Edwin Molyneux, which, in the tabulated lists and analysis, may be expected to take the foremost position amongst the recent introductions.

CHRYSANTHEMUM PRINCESS OF WALES.

THE voting as tabulated on page 10 of the National Society's catalogue places this very fine variety in a not very favourable position.

FIG. 51.—CHRYSANTHEMUM AVALANCHE.

in mature blooms, some being split at the edges. The finest bloom we have seen was that from Mr. E. Molyneux, certificated at Southampton on the 1st inst., this being 7 inches in diameter and 5 inches deep. It has also been certificated at several other shows, including Kingston and the Crystal Palace, the bloom at the last named place being exhibited by Mr. Packman. As an exhibition variety it will undoubtedly take a high place, as the samples shown this year will be sufficient inducement to

There are eight places in a list of thirty-six varieties which are so arranged that those which received an equal number of votes are bracketed together. Ten varieties occupy the second position in the list, whereas Princess of Wales is bracketed with three others only, and these only moderate companions, one of them particularly so—Venus. Seldom indeed is a good or even a moderate bloom of this variety staged, as good blooms go nowadays, while Princess of Wales is by many regarded

as having few equals and less superiors. Take for another instance Prince of Wales, which I regard as quite an inferior variety, as it lacks the most important points in an incurved bloom—depth and solidity. Seldom indeed is this variety seen with a full centre; generally the petals are thin and loose, the bloom altogether flat. Still the Prince stands before his royal consort in position in the voted list. The only reason I can assign for the adverse position of this favourite, and one which it does not deserve, is that generally it is not well cultivated owing to no fault of its own. For this reason it gets the character of not being one of the best, whereas under the best treatment it has been able to hold its own against all comers. Only once has it been my lot to see six blooms of any other sort capable of surpassing the Princess. The superior stand in this case was Lord Alcester. One fault which Princess of Wales possesses is that of being shy in producing cuttings early. In this manner valuable time is lost in the growth of the plants, which can never be made up by any kind of treatment. The variety is then often neglected by the ordinary cultivator. I fancy a leading exhibitor would think he was but badly off if a bloom of Princess of Wales was not forthcoming for a stand of blooms in an important class, certainly would it be regarded by such exhibitors and the judges as possessing more merit than either Mr. Bunn or Baron Beust for instance. Growers of Incurved Chrysanthemums know well the value of such sorts as Princess of Wales in close competition.

Taking into consideration also the list of forty-eight Japanese varieties which are classed into thirteen divisions, which are bracketed together according to the number of votes obtained, Madame C. Audiguier in my opinion is entitled to rank quite at the head of the list; certainly it is more meritorious than M. Tarin, Balmoreau, Comte de Germiny, or even Baronne de Prailly. As far as I know this variety has only one fault, that of extremely tall growth, making it unpopular with those who have not the necessary convenience of accommodation.—E MOLYNEUX.

WHAT CAUSES "DAMPING-OFF" IN CHRYSANTHEMUM BLOOMS?

THIS is a question of considerable importance among the exhibition growers in several parts of Ireland, as pointed out by Thomas Phelan, Esq., of Spring Gardens, recently. I have seen many of the collections—I am now referring to those grown for large exhibition blooms—and none are safe. I may at once say those grown for decoration or for trial—including the newer introductions, such as Avalanche, White Cérés, James Carter, Mrs. Beale, Ralph Brocklebank, Alice Bird, Elsie, Lady Lawrence, Mrs. H. Cannell, Edouard Audiguier, Mrs. J. Wright, and Amy Furze—are, with me, quite free from damp; while 300, the majority being Japanese, against a partially protected south wall, are equally so. Those grown for large exhibition blooms are then alone to be considered; so this narrows the subject.

Mr. Phelan is among the best amateur exhibition growers in Ireland, and in last issue he attributes this general damping-off in this locality to the effect of the cool wet summer and consequent insufficient ripening of the foliage and wood, and that they are now surcharged with sap. This is probably right as far as it goes, but from careful examination and thinking the matter over I think constant feeding with stimulants under those circumstances is the real cause. For maturation purposes the amount of sunshine last summer has been estimated at 30 per cent. less than in the previous year. As this is the great agent for the elaboration of the sap and the process of ripening, the deficiency was a third less. It is this, too, that has thrown back the time of blooming from ten days to a fortnight. Feeding plants with stimulants then, when they must have had a difficulty in assimilating what was already fit for absorption, partly from the constant rains, was, and must have been at times, a work of supererogation. I respectfully submit then—but will duly defer to the opinions of Messrs. J. Wright, Lewis Castle, or E. Molyneux for instance—that if we are to have another comparatively sunless and moist summer the use of stimulants, if any, must be greatly curtailed and only given where the pots are comparatively small and as the ripening and building up of the tissues proceed. One word as to small pots. I was kindly shown through the Duke of Buccleuch's collection of some 2000 Chrysanthemums at Dalkeith Palace Gardens last September by Mr. Malcolm Dunn and his intelligent foreman, Mr. Brough. The plants were in pots ranging from 5½ to 8 inches, none larger, but regularly fed with a variety of stimulating liquids as they required it. Finer and healthier plants I never saw, with in every instance foliage to the rims of the pots. A party of Yorkshire gardeners were admiring them the day before. This set me thinking as to the necessity of 10 or 12-inch pots when stimulants are regularly administered; but the matter only indirectly bears on the above query.—W. J. MURPHY, *Clonmel*.

CHRYSANTHEMUMS AT FROYLE PARK, ALTON, HANTS.

AT the gardens of T. Oliverson, Esq., under the superintendence of Mr. H. Coster, Chrysanthemums have for several years constituted an important specialty, and Mr. Coster has this season excelled all his former efforts to produce good plants and blooms. And Mr. Coster attributes much of his success to his employer allowing him the necessary facilities required to produce such grand plants and blooms. There are 600 plants grown for large blooms, chiefly from crown buds, and the majority of the blooms are fit for exhibition. At the present time there is a grand display in the conservatory; about 500 plants are arranged in one group, all the pots standing on the level ranging from 3 to 10 feet in height. Enumerated are all the recent, new, and approved

older varieties, and I must admit never before has it been my privilege to inspect such a magnificent display in a private establishment. Japanese, incurves, and reflexed are well represented both in colour and varieties. They are remarkable for their purity, cleanness, and solidity. Noticeable among the Japanese are Stanstead White, M. Freeman, Sarah Owen, Florence Percy, Avalanche, Soleil Levant, Marguerite Marrouch, M. J. Laing, Moonlight, Madame C. Audiguier, Grandiflorum, J. Délaux, M. Délaux, and Criterion. These are all of great size. Edwin Molyneux and Ralph Brocklebank are just unfolding some very large buds, the former variety looking very promising.

The best of the incurved were Jeanne d'Arc (grand bloom), Lord Wolseley, Lord Alcester, Queen of England, Bronze Queen of England, Empress of India, Golden Empress of India, Prince Alfred, and many others too numerous to mention. The most noticeable among the reflexed was Cullingfordi, Cloth of Gold, King of the Crimson, Christine, and Golden Christine. Another conspicuous feature at Froyle Park is a large quantity of Poinsettia pulcherrima with its brilliant colouring of scarlet bracts of large dimension.—VISITOR.

FLORA OF THE KERMADEC ISLANDS.

UPWARDS of thirty years ago Sir Joseph Hooker published an account of the botany of Raoul or Sunday Island, one of the Kermadec Group (Journal of the Linnean Society, i., pp. 125-29), founded upon a small collection made by McGillivray and Milne, naturalists attached to H.M.S. "Herald." This collection consisted of forty-two species, of which twenty were flowering plants, and the rest Ferns and Lycopods; and the most interesting circumstance connected with it was "the identity of most of the flowering plants, and all but one of the Ferns, with those of New Zealand."

In 1815, Mr. J. T. Arundel presented to the Kew Herbarium a collection of fourteen species from Meyer, a small rocky islet about a mile and a half north of Sunday Island. Poor as it was, it contained half a dozen plants not previously known from the group, though they are all included in the collection referred to below.

Since then, no further light has been thrown on this insular flora until the quite recent appearance (Transactions of the New Zealand Institute, xx., pp. 151-81) of a paper by Mr. T. F. Cheeseman, Curator of the Auckland Museum, New Zealand, a copy of which was kindly forwarded to the writer. Mr. Cheeseman was permitted, through the kind offices of Mr. Percy Smith, the Assistant Surveyor-General of New Zealand, to accompany the expedition despatched last year for the purpose of formally annexing the group to the colony of New Zealand. If Mr. Cheeseman has not succeeded in exhausting the botany of the Kermadec Islands, which, of course, is hardly probable, the undiscovered species cannot materially affect the question of the origin of the vegetation. But before giving the results of his investigations it will be useful to indicate the position and extent of the islands.

A short note was recently given on the subject, but the following further particulars are interesting.

The information obtained points unmistakably to New Zealand as the source of the greater part of the flora of the Kermadec Islands. How the plants reached these islands is an interesting question. Mr. Cheeseman is prepared to admit a former north-western extension of New Zealand; but, after a careful examination of the evidence, he arrives at the conclusion that the Kermadec Islands have always been isolated, or, at least, have not formed part of any other land since the Secondary period. Spores of the Ferns may have been conveyed by winds; and ocean currents and birds it may well be conceived have operated in stocking the islands with flowering plants. Most of the birds are New Zealand species, and the presence of Kauri logs, of different dates and brands, stranded on various parts of the beach, is convincing evidence of the direction of ocean currents. Moreover, the composition of the flora strongly supports this theory.

Sunday Island is the only one of the group on which there is anything approaching arboreal vegetation, and this, with the exception of a small area of the crater, is clothed with forest from the seashore to the tops of the highest peaks. The prevailing tree is *Metrosideros polymorpha*, one of the most characteristic trees of Polynesia, especially of the smaller islands, reaching the Sandwich, Marquesas, and Pitcairn Islands; but this particular species does not occur in New Zealand nor in Australia.

Next to the *Metrosideros* in abundance and conspicuousness is a Palm, which Mr. Cheeseman thinks may be identical with the Norfolk Island *Rhopalostylis Baueri* (*Areca Baueri*). In some places this grows gregariously, forming large groves.

Ferns are everywhere abundant, varied, and luxuriant; and the endemic Tree Fern, *Cyathea Milnei*, is very plentiful, and handsome withal, rising to a height of 50 or 60 feet. Prominent among the New Zealand trees are *Corynocarpus laevigatus*, *Myoporum laetum*, *Melicope ternata*, *Melicytus ramiflorus*, and *Panax arboreum*. *Cordylina terminalis*, the widely-spread Polynesian "Ti," and *Pisonia Brunonian*, *Pittosporum crassifolium*, *Coprosma acutifolia*, and *C. petiolata*, natives of New Zealand, are other elements deserving of notice.

The herbaceous vegetation includes no plants with conspicuous flowers, but there are two Orchids—namely, *Acianthus Sinclairii*, a native of New Zealand, and *Microtis porrifolia*, which also inhabits both New Zealand and Australia. Macaulay Island was entirely covered with a beautiful sward of natural grass, supposed to be composed of a species of *Poa* and an *Agrostis*, but in the absence of flowers they were in-

determinable. Students of botanical geography will find much more that is interesting in Mr. Cheeseman's valuable paper, from which I have extracted the principal facts.—W. B. H. (in *Nature*).

CHRYSANTHEMUM SHOWS.

THE NATIONAL SOCIETY'S SHOW.—NOVEMBER 7TH AND 8TH.

LAST week we were compelled to dismiss the great Show at the Royal Aquarium, Westminster, in a very brief report, and in returning to it now we can only give some additional particulars concerning the varieties shown in the first prize collections, and a general review of the Show. That it was an exceedingly satisfactory exhibition may be judged from the large increase in the number of entries (504), the space occupied, the good quality of the blooms throughout, and the great attendance of visitors (over 10,000 on the first day alone). What such a show would have been arranged in one large building can be readily imagined. Much of the effect was, however, necessarily spoiled by the exhibits being unavoidably separated and distributed throughout the main building in the side galleries and St. Stephen's Hall.

It was not only an exhibition of Chrysanthemums, but the display of vegetables and fruit in competition and otherwise would alone have formed a show of no mean importance, while in addition there were horticultural sundries, greenhouses, and appliances in strong force. With regard to the latter a very judicious system was adopted of charging for the space occupied, and many societies might follow this out with advantage to themselves.

The Societies' challenge trophy for forty-eight cut blooms, twenty-four incurved, in not less than eighteen varieties, and twenty-four Japanese, distinct, was, as we stated last week, won by the Weald of Kent Society, represented by Mr. Doughty, Angley Park Gardens, Cranbrook; with the following varieties in excellent condition, the flowers substantial and clean:—Incurved, back row—Lord Alcester, Alfred Salter, Empress of India, Emily Dale, Lord Alcester, Alfred Salter, Empress of India, and Queen of England; middle row—Bronze Queen, Golden Empress, Prince Alfred, Mrs. Heale, Prince Alfred, Golden Empress, Lord Wolseley, and Jeanne d'Arc; front row—Mrs. W. Shipman, Hero of Stoke Newington, Jeanne d'Arc, Empress Eugénie, Prince of Wales, Violet Tomlin, Jardin des Plantes, and Lady Hardinge. The Japanese were similarly good, the varieties being, in the back row, Baronne de Prailly, Fair Maid of Guernsey, Edwin Molyneux, Madame B. Rendatler, Val d'Andorre, Boule d'Or, and Madame Baco; middle row—M. Astorg, Carew Underwood, Hiver Fleuri, Belle Paule, Madame Paul Detour, Dormillon, Madlle. Lacroix, and Madame C. Audiguier; front row, Comte de Germiny, Grandiflorum, Madame de Sevin, Meg Merrilies, Criterion, Dr. Macary, Triomphe de la rue des Châlets, and Peter the Great.

In another large class, that for forty-eight incurved, not less than twenty-four varieties or more than three blooms of one variety, Mr. Doughty was also the premier exhibitor, staging grand examples of the following, arranged in the order named:—Back row—Lord Alcester, Alfred Salter, Empress of India, Lord Wolseley, Golden Empress, Prince Alfred, Emily Dale, Alfred Salter, Lord Alcester, Bronze Queen, Golden Empress, Lord Wolseley, Emily Dale, Prince Alfred, Lord Alcester, and Alfred Salter. Middle row—Princess of Wales, Jeanne d'Arc, Prince Alfred, Queen of England, Violet Tomlin, Empress of India, Mrs. W. Shipman, Golden Empress of India, Empress Eugénie, Queen of England, Violet Tomlin, Jeanne d'Arc, Princess of Wales, Empress of India, Empress Eugénie, and Queen of England. Front row—White Venus, Lady Hardinge, Jardin des Plantes, Venus, Charles Gibson, Hero of Stoke Newington, Jeanne d'Arc, Antonelli, White Venus, Cherub, Mrs. Norman Davis, Venus, Mrs. Halliburton, Cherub, Jardin des Plantes, and Princess of Wales.

With twenty-four incurved, distinct varieties, Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, was awarded premier honours, his stand containing the following varieties, represented by beautifully fresh compact blooms:—Back row—Empress of India, Golden Empress, Lord Wolseley, Queen of England, Lord Alcester, Prince Alfred, Emily Dale, and Alfred Salter. Middle row—John Salter, Jeanne d'Arc, Jardin des Plantes, Beauty, Nil Desperandum, Mr. Bunh, Prince of Wales, and Mr. Brunlees. Front row—Princess Beatrice, Golden Perfection, Venus, Barbara, White Venus, Mrs. Shipman, Prince of Wales, and Lady Hardinge.

The class for forty-eight Japanese blooms, not less than twenty-four varieties, or more than two blooms of one variety, was an extraordinary one, fourteen competitors staging fine blooms, the consideration of which occupied the Judges for over an hour. Ultimately Mr. J. McKenzie, gardener to T. S. W. Cornwallis, Esq., Linton Park, Maidstone, was awarded the premier prize for handsome blooms of the under-mentioned varieties. Back row—Ralph Brocklebank, Comtesse de Beauregarde, Madame B. Pigny, Edwin Molyneux, Meg Merrilies, Carew Underwood, Soleil Levant, Baronne de Prailly, Mrs. J. Wright, Carew Underwood, Soleil Levant, Meg Merrilies, Edwin Molyneux, Madame B. Pigny, and Comtesse de Beauregarde. Middle row—Marguerite Marrouch, Madlle. Lacroix, Madame J. Laing, Thunberg, Madame C. Audiguier, Maiden's Blush, Val d'Andorre, Stanstead White, Val d'Andorre, Mrs. H. Cannell, Madame C. Audiguier, Maiden's Blush, Thunberg, Baronne de Prailly, Madlle. Lacroix, and Marguerite Marrouch. Front row—Florence Percy, Criterion, Elaine, M. Brunet, L'Adorable, Balmoreau, Mrs. H. Cannell, Gloriosum, Belle Paule, L'Adorable, J. Délaux, M. Brunet, Elaine,

Madame J. Laing, Florence Percy, and one name we missed. Messrs. Packman and Munro won the second and third prizes.

The best twenty-four Japanese in a class of twelve exhibitors were shown by Mr. C. Cox, gardener to J. Trotter, Esq., Buckenden Grange, Hertford, who had the following varieties. Back row—Album Plenum, Belle Paule, M. Tarin, Meg Merrilies, Madame C. Audiguier, Edwin Molyneux, Soleil Levant, Fair Maid of Guernsey; middle row—Madame de Sevin, Ralph Brocklebank, Madlle. Lacroix, Thunberg, Carew Underwood, Peter the Great, Comte de Germiny, and Spectre Toulousain; front row—Snowstorm, Val d'Andorre, Criterion, Hiver Fleuri, Yellow Dragon, La Triomphante, J. Délaux, and M. Astorg.

Mr. T. Skinner, East Surrey Park Gardens, had the leading box of twelve Japanese, and amongst sixteen competitors secured the first prize. He showed capital examples of the following: Madame C. Audiguier, E. Molyneux, Baronne de Prailly, Carew Underwood, Maiden's Blush, Golden Dragon, Madame B. Pigny, J. Délaux, Dormillon, Meg Merrilies, Val d'Andorre, and Edouard Audiguier.

There were ten entries with twelve Japanese reflexed, Mr. J. Hewitt, Hillside House Gardens, Hythe, being first for fine blooms of Val d'Andorre (3), Maiden's Blush (3), Criterion, M. Astorg, L'Adorable, Amy Furze (2), and J. Délaux. Mr. C. Cox had the best stand of twelve reflexed, Mr. Sullivan the finest twelve large Anemones, and Mr. Jukes the best twelve Anemone Japanese, very handsome blooms.

Specimen plants were well shown by Messrs. J. Brooks, E. Easey, W. Davey, S. Gilbey, F. E. Wright, and R. Cooper. The leading groups came from Messrs. Davis & Jones, J. Hudd, J. Laing & Son, and J. Witty.

In the fruit classes Grapes were excellent, Messrs. A. Luff, C. J. Goldsmith, and G. Duncan taking the prizes for white varieties. Mr. Howc had the best black Grapes, Messrs. Batten and J. Barry following. Mr. Lambert, Shrewsbury, staged the finest Gros Colman, Mr. J. Craven and W. Allan being second and third. Mr. C. J. Goldsmith won the premier award for dessert Apples, and Mr. I. McKenzie for culinary Apples, Mr. Goldsmith also being first for six dishes of Pears.

The competition in the classes for Potatoes, and the special prizes for vegetables offered by Messrs. Sutton & Sons, Webb & Sons, Deverill and Co., and C. Fidler, was very keen. The miscellaneous exhibits also from the principal seed and nursery firms were both abundant and interesting.

BATH.—NOVEMBER 7TH AND 8TH.

THIS Society, with Alderman Chaffin at its head and Mr. B. Pearson as Secretary, held a highly successful Exhibition on the above date. Although nominally a Chrysanthemum Show fairly good prizes were offered for other plants as well as fruit and vegetables, and in nearly every class the competition was close and the exhibits numerous.

PLANTS.—The Veitch Memorial medal and £5 were offered as the first prize in the class for eight specimens, distinct, four to be Japanese and four of large flowered varieties, pots not to exceed 12 inches in diameter. Six competed, but two of them far surpassed the rest. The first prize was eventually awarded to Mr. R. B. Cater, who had a very even collection, each plant being flatly trained, about 4 feet through, and carrying on an average seventy good blooms, the foliage also being good; the varieties Madame Bertie Rendatler, M. Jean Marie Pigny, Source d'Or, Margot, Lord Wolseley, Mrs. Dixon, Prince Alfred, and Mrs. G. Rundle. The Rev. E. Handley (gardener, Mr. S. Kerslake) Bath, was a close second, two plants rather smaller than the rest being the only drawback to the collection. The third prize was awarded to Major W. P. Clarke, Trowbridge. There was a great falling off in the class for four dwarf trained plants, and with these Mr. M. Cole was first, Mr. H. C. Smith second, and the Rev. C. C. Layard third. Mr. Cole was also first for three well flowered standard-trained plants. In a corresponding class for Japanese varieties Mr. S. P. Budd (gardener, Mr. W. Davis), Bath, was well first, and Mr. E. B. Titley second, both had very freely flowered plants. Mr. M. Cole was first for conservatory plants, and Mr. T. Jolly (gardener, Mr. A. Hawkins), Bath, second. Mr. R. B. Cater had the best pyramid large flowered variety, the second prize going to Mr. S. P. Budd. In the class for a flatly trained specimen of large flowered variety Mr. W. J. Brown (gardener, Mr. J. Southard) had a fine plant of Mrs. G. Rundle, fully 6 feet through, and was first, the second prize being awarded to Mr. Cater, who also had a good specimen. There were also classes provided for specimen plants of Pompons and Anemone flowered varieties, but in most instances those staged were much too backward to be attractive. Good prizes were offered for groups of Chrysanthemums to occupy a space 12 feet by 6 feet, and of these there were five arranged. The first prize was rightly awarded to Mr. R. B. Cater. Mr. S. P. Budd followed, the plants in this case being dwarfed, and the blooms were fine and fresh, but the front was decidedly weak. The third prize went to the Rev. E. Handley.

MISCELLANEOUS PLANTS.—Mr. R. B. Cater was the only competitor with six Orchids, and was awarded the first prize. Of these the most noteworthy were *Odontoglossum Sanderianum*, *Oncidium tigrinum*, and *Oncidium Rogersi*. A freely flowered *Lapageria rosea* gained Major W. P. Clarke the first prize in the class for one flowering plant. Mr. E. E. Bryant (Mr. W. J. Mould, gardener) being second with *Allamanda Hendersoni*. The best four fine-foliaged plants were staged by Mr. C. Doherty (gardener, Mr. H. Jones), the second prize going to Mr. R. B. Cater. Mr. A. A. Walters, Bath, was first for six good table plants, and Mr. J. Cray, Frome, second. Bouvardias were not so good as usual; Mr. W. Pumphrey (gardener, Mr. J. J. Tate) was first, and Messrs. G. Cooling & Sons second. Primulas made quite a fine display,

the raised centre of one long table being closely filled with them. For twelve plants Mr. M. Cole was well first, the second prize going to Mr. C. Fisher. In the next class, that for six plants, Mr. Jerome Murch was first, and Mr. T. Carr (gardener, Mr. T. Frickle) second; while for double Primulas, Mr. J. Murch was first and Mrs. Hoare (gardener, Mr. F. Rice) second. There were three collections of plants arranged for effect in a space not less than 12 feet by 4 feet. The Judges had no difficulty in awarding the first prize, Messrs. G. Cooling & Son, Bath, being well ahead of the other competitors. Their arrangement was somewhat formal, but a capital assortment of Ferns, Palms, Crotons, Dracenas, Orchids, and other choice flowering plants was employed. Mr. E. E. Bryant was second, the arrangement in this case not being sufficiently close to well hide the pots. Mr. W. C. Drummond was third.

CUT FLOWERS.—There were five entries in the class for twenty-four distinct varieties of large flowered Chrysanthemums, and the Judges were a considerable time in making their awards. The first prize was ultimately awarded to Mr. W. M. Baker, (gardener, Mr. J. Applin), Harefield Court, Gloucester, who had many fine but not particularly well set up blooms. In all probability had judging by points been resorted to, the winner of the second prize, the Earl of Radnor (gardener, Mr. H. W. Ward), Salisbury, would have been placed first, good dressing being apparent throughout the stands of well grown blooms shown by this competitor. His best was Empress of India (this securing the silver medal of the National Chrysanthemum Society, which was offered for the best bloom in the Show). Lord Heytesbury (gardener, Mr. J. Horsefield), Heytesbury, Wilts, took the third prize, and was also first for twelve varieties, these comprising Empress of India, Golden Empress, Lord Wolseley, Queen of England, Jeanne d'Arc, Alfred Salter, Golden Queen of England, Nil Desperandum, Jardin des Plantes, Princess Teck, Prince Alfred, and Lady Hardinge, all good. Lord Radnor was a good second, and Mr. A. Cole (gardener, Mr. W. Carpenter), third. Major W. P. Clarke was first for six varieties, Mr. S. P. Budd second, and Mr. M. Hookings third. Japanese varieties were very well shown, a very few points dividing the prizewinners. The first prize for twenty-four varieties was awarded to Mr. Wilfred Thomas (gardener, Mr. Thomas), Taunton, who had fine blooms of Boule d'Or, Madame C. Audiguier, Meg Merrilies, Thunberg, Belle Paule, Carew Underwood, Avalanche, Elaine, M. J. N. Pigny, Soleil Levant, Ralph Brocklebank, and Criterion. Mr. H. W. Ward was second. The third prize was awarded to Captain Alcock (gardener, Mr. A. Parker). Mr. W. Marshall was again first for twelve varieties, and Mr. W. M. Baker was second. Mr. M. Cole was first for six blooms, and Mr. M. Hookings was second. There were comparatively few Anemone-flowered varieties shown. For twelve blooms in not less than six varieties Lord Radnor was placed first, the second prize going to Mr. W. Marshall for what apparently was the better stand of the two.

For a vase or epergne of cut flowers Mr. C. Winstone, Clifton, was first, and Mr. M. Hookings second, both displaying great taste. The first named was also first for a hand bouquet, and Messrs. Garaway and Co., Clifton, second, the former having the more elegant arrangement, and both used very choice flowers.

FRUIT AND VEGETABLES.—There was as usual a very fine display of Grapes in the three classes provided for them. The best four bunches in not less than two varieties were staged by Alderman Chaffin (gardener, Mr. W. Taylor), these consisting of Muscat of Alexandria, each of the two bunches weighing upwards of 5 lbs., and were well finished, with these being fairly good Alicante. Mr. T. Jones staged fine Gros Colman and Alicante, and was second; the third prize going to Mr. S. Fox Andrews (gardener, Mr. T. Haste). Mr. Chaffin was also first for three very fine bunches of Muscat of Alexandria; Earl Cowley (gardener, Mr. J. Gibson) being a most creditable second. In the class for any variety of black Grapes, Mrs. Gouldsmith (gardener, Mr. G. Pym), Trowbridge, was well first with grand bunches of Gros Colman, these being perfect in every respect; Mr. T. Jones was second with very good Alicante. A grand lot of Pears were shown in the several classes provided for them. For six varieties, the first prize was awarded to J. D. Wingfield Digby, Esq. (gardener, Mr. W. G. Pragnell), Sherborne, these consisting of very fine Pitmaston Duchess, Beurré Diel, Marie Louise, Duchesse d'Angoulême, Doyenné du Comice, and Beurré Clairgeau; Mr. E. Hall was second. With four varieties, Mr. C. B. Weaver was first, staging extra good Marie Louise, Doyenné du Comice, Louise Bonne of Jersey, and Pitmaston Duchess; Captain Alcock was a good second, and there were thirteen other lots shown. Mr. C. B. Weaver was also awarded the first prize in a very large class for a single variety fit for the table, winning with extra fine fruit of Prince Imperial, this being another name for Pitmaston Duchess; Mr. C. Fisher was second. Apples were also largely shown. The best six dessert varieties, consisting of Newtown Pippin, Ribston Pippin, Blenheim Pippin, King of the Pippins, Royal George, and Jackson's were staged by Mr. E. Hall; J. D. W. Digby, Esq., being a good second. For four dessert varieties, Mrs. Pinder (Mr. J. Riddick, gardener) was first, and Mr. E. T. Hall second. Kitchen Apples were extra good, the Dorset and Somerset dishes quite eclipsing those sent from Hor ham in Sussex. For six varieties, Mr. J. D. W. Digby was first, the collection consisting of very fine dishes of Peasgood's Nonesuch, Cox's Pomona, Ecklinville, Mère de Ménage, Warner's King, and Hawthornden; Mr. W. H. Long, M.P. (Mr. A. Miller, gardener), was a good second. Four competed in the class for six varieties of dessert fruit. The Marquis of Bath (Mr. W. Pratt, gardener), Longleat, was placed first, having beautifully finished Muscat of Alexandria and good Alicante Grapes, Late Admirable Peaches, Coe's

Golden Drop Plums, King of the Pippins Apples, and Gansel's Bergamot Pears; Mr. H. W. Tugwell (gardener, Mr. J. Ellicott), Bath, was second, the Lady Downe's and Muscat of Alexandria Grapes being good in this collection. Only one class was provided for vegetables. For a collection to occupy a space 4 feet by 3 feet, Mr. J. D. W. Digby was well first, having extra fine examples of Celery Wright's Grove White, Broccoli Veitch's Autumn Protecting, Tomato Hackwood Park, Brussels Sprouts The Aigburth, Potato Reading Russet, Carrot Veitch's Matchless, Parsnip The Student, and Onion Rousham Park. The second prize also came from the Sherborne district and was of great merit. Mr. W. E. S. Erle Drax (Mr. J. H. Copp, gardener), Holnest Park, was the exhibitor.

PORTSMOUTH.—NOVEMBER 7TH, 8TH, AND 9TH.

A LARGER and finer exhibition than ever was held by this flourishing southern society in the Drill Hall, Landport, on the dates named. The great building is specially adapted for such a show, as ample space is afforded for the exhibits as well as for visitors, the secret of the large attendance being the popular low prices for admission. As showing the advance in competition in almost all classes it may be stated that six tables, 108 feet long each, 10 feet longer than last year, were required instead of four as before to display the exhibits of eat blooms, fruit, and vegetables. The staging of the exhibits was ably carried out by Mr. Collins and his assistants, reflecting credit upon them, and Mr. Power, the courteous Honorary Secretary, was indefatigable in his duties to make the Exhibition what it was, a splendid success.

PLANTS.—Trained plants were staged on the floor down the centre of the Hall, and being mostly of good quality made an imposing display. Jubilee prizes of £10, £5, and £2 10s. were offered for eight specimens, four incurved or reflexed and four Japanese. Mr. H. Joy, nurseryman, Shirley, Southampton, was an easy first with splendid examples from 4 to 5 feet in diameter, profusely flowered and neatly trained, William Robinson, Bouquet Fait, Golden Christine, Mrs. Forsythe, Dr. Sharpe, Hiver Fleuri, and Madame Bertie Rendatler were the best. Mr. Mills, gardener to Mrs. Pearce, The Firs, Bassett, Southampton, was second, staging smaller specimens. Another class for eight plants was set apart for which Mr. Penford was the only competitor, staging creditable examples of leading varieties. For the best group of Chrysanthemums, arranged in a space 50 square feet, there were the unusual number of twelve competitors. The first prize was awarded to Mr. H. Gate, gardener to G. Cook, Esq., Gosport, for plants characterised by excellent blooms, but the arrangement was faulty. The second prize was awarded to Mr. Hatch for a capitally arranged group, and the plants being well grown, but the extra sized flowers of the first prize group carried the day owing to the absence of special regulations to the contrary in the schedule. Mr. W. Roberts, gardener to E. R. Longcroft, Esq., Hall Place, Havant, was an excellent third. Three extra prizes were given in this class, and right well they were merited. For a single specimen plant Mr. Joy staged Madame Bertie Rendatler, from 5 to 6 feet in diameter, quite covered with bloom. Table plants, Primulas, and Solanums were well shown by Messrs. Molyneux, Agate, and H. Drover, Ventnor.

CUT BLOOMS.—These were both numerous and good, 1800 being placed in competition. The increased number of entries showed that much interest is being taken in the cultivation of Chrysanthemums in the Portsmouth district, while the quality throughout was above the average for the year.

The principal class was that for thirty-six blooms, eighteen to be Japanese and eighteen incurved, distinct, for which the second challenge trophy was offered, value £25 and £6 in money, while the second prize was £5; third, £2 10s., and fourth, £1. Six entered the list, making a capital show. Messrs. W. & G. Drover, nurserymen, Fareham, were easy winners; the incurved blooms were large and fresh, while the Japanese were of good quality, and all staged well. The varieties were as follows:—Japanese—Back row—Boule d'Or, Baronne de Prailly, Gloriosum, Edwin Molyneux, Madame C. Audiguier, and Carew Underwood. Middle row—M. J. M. Pigny, Marguerite Marrouch, Meg Merrilies, Fimbriatum, Ralph Brocklebank, and Madame Baco. Front row—Criterion, Belle Paule, Jean Delaux, Mdle. Lacroix, Val d'Andorre, and Avalanche. Incurved—Back row—Golden Empress, Empress of India, Queen of England, Golden Queen of England, Alfred Salter, and Lord Alcester (grand). Middle row—Prince Alfred, Mrs. W. Shipman, Novelty, John Salter, Mrs. Heales, and Lord Wolseley. Front row—Lady Hardinge, Empress Eugénie, Nil Desperandum, Princess of Wales, Jardin des Plantes, and Jeanne d'Arc. Mr. Neville, gardener to F. W. Flight, Esq., Twyford, Winchester, was second, the Japanese and incurved also being smaller but capitally finished. Mr. Penfold, gardener to Sir F. Fitz-Wygram, Leigh Park, Havant, third, who staged his blooms much too low. Fourth, Mr. J. Inglefield, gardener to Sir J. W. Kelk, Bart., Tedworth, Marlborough.

The next important class was for twenty-four blooms, half Japanese and the remainder incurved, seven competitors. Mr. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham, was easily first, his blooms being of good quality, though not "monsters," while they were staged in his usual good style. Japanese:—Edwin Molyneux, Baronne de Prailly, Meg Merrilies, Madame C. Audiguier, Avalanche, Val d'Andorre, Mrs. Falconer Jameson, Ralph Brocklebank, Boule d'Or, Belle Paule, Golden Dragon, and Madame Laing. Incurved:—Empress of India, Golden Empress, Alfred Salter, Queen of England, Golden Queen of England, John Salter, Lord Alcester, Lord Wolseley, Bronze Queen of England, Jeanne d'Arc, Nil Desperandum, and

Princess Beatrice. Mr. Trinder, gardener to Sir Henry J. St. Mildmay, Dogmersfield Park, Winchester, was second, staging heavy Japanese and large incurved, but some a little rough. Mr. Neville was third, staging light but clean blooms. A somewhat novel class was next staged, twelve of Mrs. G. Rundle, twelve George Glenny, and twelve Mrs. Dixon, for which the sum of £4 was offered as the first prize. It cannot be said the blooms were worthy of the prizes given. Messrs. Drover were first; Mr. Penfold, second; and Mr. Woodfine, gardener to Captain Boyd, Emsworth House, Havant, third. Four competed in the class for twelve Japanese, distinct, the best coming from Mr. Inglesfield, a heavy lot, the names being Baronne de Prailly, Meg Merrilies, Madame C. Audiguier, Ralph Brocklebank, M. Brunet, Boule d'Or, Edwin Molyneux, Mons. Freeman, Jeanne Delaux, Belle Paule, Criterion, and Mrs. J. Wright. Mr. Molyneux was an exceedingly close second; Mr. Trinder third. For twelve incurved, distinct, four competed, Mr. Molyneux easily leading the way with an even stand, Empress of India, Golden Empress, Lord Alcester, Queen of England, Alfred Salter, Prince Alfred, Lady Hardinge, Lord Wolseley, Empress Eugenie, John Salter, Jeanne d'Arc, and Mrs. Heale. Messrs. Drover were second, staging rather rough blooms; Mr. G. Inglesfield, third. For twelve reflexed, in not less than eight varieties, Mr. Woodfine was first, staging medium-sized blooms; Mr. W. Covell, gardener to J. A. W. Martin, Esq., West Leigh, Havant, second. Five staged twelve Anemones, large varieties in not less than six varieties. Messrs. Drover were easily first with full centred blooms of Nouvelle Alveole (2), Laing's Anemone (2), Miss Annie Lowe (2), being the best. Second, Mr. J. Horril, The Union, Havant. Mr. J. Agate, Havant, third. Messrs. Drover were also first with twelve Japanese Anemones, staging substantial blooms good in colour, the best being Fabian de Mediana, Margouline, and Jean Marty. Mr. W. Covell was second.

Pompons made a good show. Six staged twelve bunches, three blooms to a bunch, of Pompons, not less than eight varieties. Mr. Neville was easily first, Mrs. Telford, President, and Mdlle. Elise Dordan being the best varieties. Mr. G. Russell, gardener to Dr. J. Lewis, Henfield, Sussex, was second. Twelve bunches of fimbriated varieties, three blooms to a bunch, formed an attractive class. Mr. Hatch, gardener to the Victoria Park Committee, was the first prize winner, Chardonnet, Scipio, and Belle Navaraise being especially fine. Mr. Agate second. For twelve bunches of single varieties, three blooms to a bunch, six competed, making a charming display. Mr. Agate was a good first, Snowflake, Ox Eye, Nellie, Mary Anderson, Patience, and Mdlle. La Mout being most noteworthy. Mr. Hatch was a good second. For the best two blooms of incurved and Japanese, arranged in separate glasses, ten competed, Mr. Molyneux was easily first with Empress of India and Edwin Molyneux. Second, no name. The premier incurved bloom was a very fine one of Lord Alcester in Messrs. Drover's cup stand, and the premier bloom in the Japanese section was found in Mr. Trinder's stand, a grand Boule d'Or.

For twenty-four blooms, to consist of six Japanese, six incurved, six reflexed, and six Anemones, open to growers in Portsea Island only, a handsome silver cup and £3 were offered as the first prize. There was keen competition. Mr. Hatch was easily first with good even stands: Incurved, Madame C. Audiguier, M. J. M. Pigny, Madame Baco, Avalanche, Hamlet, and Madame Laing; Japanese, Jeanne d'Arc, Bronze Queen of England, Golden Empress, Empress of India, Lord Alcester, and Queen of England; Reflexed, Amy Furze, Dr. Sharpe, King of Crimson, Golden Christine, Cullingfordi, and Chevalier Damage; Anemones, Annie Lowe (2), Empress, Prince of Anemones, Gluck, Fleur de Marie. Many other classes were set apart for local competitors, in most of which there was strong competition and good blooms.

FRUIT.—This formed a creditable display. For six bunches of Grapes, three black and three white, for which the handsome sum of £5 was offered as first prize, Mr. Molyneux was easily first with Alicante and Muscat of Alexandria, both very good; Mr. Penfold second with good Gros Guillaume and fair Muscats. For two bunches of black Grapes, Mr. W. Sait, gardener to General Napier, Stakes, Cosham, was first with Alicante; Mr. E. Smith, gardener to Mrs. Learmouth, Cosham, second. For two bunches of white Grapes Mr. Covell was an easy first. The heaviest bunch was one of Trebbiano from Mr. Molyneux weighing 5 lbs. 12 ozs, the next being Alicante, 4 lbs., from Mr. Smith. £5 was offered as first prize for seventy-two dishes of Apples and Pears, which brought one exhibitor only, Mr. J. Watkins, Witherington, Hereford, who staged fifty-two dishes of Apples, the majority being large, clean, and richly coloured. Pears were smaller, yet clean. The best four dishes of Pears were staged by Mr. Trinder; and Mr. Jacob, Petworth, Sussex, was first with even clean samples of Mère de Ménage, Lane's Prince Albert, and Emperor Alexander Apples.

Vegetables were staged plentifully, and of excellent quality. For eight distinct varieties, Mr. Cox, gardener to R. K. Wyndham, Esq., Corhampton House, Bishop's Waltham, was first with superior produce. Messrs. W. Cutbush & Sons, Highgate, had a stand of well grown autumn flowering plants not for competition.

CRYSTAL PALACE.—NOVEMBER 9TH AND 10TH.

THOUGH so closely following the National Society's Show at Westminster that at Sydenham on Friday and Saturday last was very satisfactory in the quality of the cut blooms, and all the more important classes attracted numerous competitors. Mr. W. G. Head arranged the exhibits in the usual effective and convenient manner in the east nave—i.e., the cut blooms on long tables, but with ample spaces between for

the visitors, the groups and some of the specimen plants being placed at the sides.

The chief of the cut bloom classes was that for forty-eight, twenty-four incurved and twenty-four Japanese, not less than eighteen varieties of each or more than two of one variety. Amongst six competitors Messrs. W. & G. Drover, Fareham, secured the leading prize (£10) with one of the most even and meritorious collections they have yet shown. The incurved were particularly clean, even, and well finished, and the varieties were as follows taken from left to right:—Back row—Lord Alcester, Golden Empress, Alfred Salter, Empress of India, Golden Empress, Lord Alcester, Lord Alcester, Alfred Salter, and Empress of India. Middle row—Mrs. Heale, Nil Desperandum, Golden Queen of England, Princess of Wales, Queen of England, Lord Wolseley, Mrs. Heale, and Mrs. W. Shipman. Front row—Prince Alfred, Novelty, Cherub, Jeanne d'Arc, Lady Hardinge, Barbara, and Empress Eugenie. The Japanese were very fresh, bright, and of good substance, the varieties being arranged as follows:—Back row—M. J. M. Pigny, Carew Underwood, Edwin Molyneux, Ralph Brocklebank, Madame Baco, Meg Merrilies, and Boule d'Or. Middle row—Gloriosum, Meg Merrilies, Boule d'Or, Madame C. Audiguier, Ralph Brocklebank, J. Delaux, and Album fimbriatum. Front row—Mr. H. Elliott, Madame Baco, J. Delaux, Mrs. J. Wright, Belle Paule, Comte de Germiny, Album fimbriatum, and Criterion. Mr. J. Horsefield, gardener to Lord Heytesbury, Heytesbury, Wilts, was a good second; Messrs. Royle & Co., Green Street, Sittingbourne, third; and Mr. J. McKenzie, gardener to F. S. W. Cornwallis, Esq., Linton Park, Maidstone, though so successful at the Aquarium two days before, had to be contented with fourth place.

The class for eighteen incurved varieties, distinct, was also a good one, eight stands being entered, and Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roelampton, secured the premier honours for solid medium size but fresh blooms of the following:—Back row—Lord Alcester, Prince Alfred, Empress of India, Queen of England, Alfred Salter, and Golden Empress of India. Middle row—John Salter, Emily Dale, Lord Wolseley, Mr. Bunn, Jeanne d'Arc, and Princess of Wales. Front row—Jardin des Plantes, Lady Hardinge, Mrs. Heale, Nil Desperandum, Princess Beatrice, and Mr. Brunlees. The second and third prizes were awarded to Messrs. A. G. Hookings and J. Horsefield respectively, both showing well.

There was a surprising competition with twelve incurved blooms, distinct varieties, no less than eighteen exhibitors entering. Mr. T. Skinner, gardener to J. Aird, Esq., M.P., East Sutton Park, won the chief award with excellent examples of Golden Empress, Lord Alcester, Emily Dale, Empress of India, Queen of England, Jardin des Plantes, Princess of Wales, Jeanne d'Arc, Alfred Salter, Prince Alfred, Mrs. Shipman, and Venus. Mr. Todd, gardener to Dr. Southey, Sutton, and Mr. J. Wyatt, gardener to J. Perry, Esq., Brodenhurst, Caterham Valley, were second and third. Fifteen stands of six incurved, one variety, were also entered, Mr. Doughty, Angley Park Gardens, leading with Golden Empress of India, followed by Mr. Hewitt with Lord Alcester, and Mr. Sadler with Empress of India.

The Japanese invariably form an important portion of this Exhibition, and that held last week was no exception to the rule. Eight stands of fine bright blooms were staged in the class for eighteen varieties, Mr. W. Packman, gardener to C. E. Shea, Esq., The Elms, Foots Cray, having the best by several points. His varieties were in the back row, Ralph Brocklebank, Madame B. Pigny, Comte de Germiny, Baronne de Prailly, Golden Dragon, and Meg Merrilies; middle row—Marguerite Marrouh, Criterion, Soleil Levant, J. Delaux, Avalanche, and Marsa; front row—Maiden's Blush, Madame J. Laing, Duchess of Albany, Florence Percy, Martha Harding, and M. J. M. Pigny. The second place was taken by Mr. T. Glen, gardener to Mrs. Montifiore, Worth Park, Crawley, and the third by Mr. J. Snow, South Park Gardens, Wadhurst, Sussex.

The seventeen stands of twelve Japanese occupied considerable space, and constituted a very interesting feature. Mr. F. Skinner was first with handsome blooms of Madame C. Audiguier, Edwin Molyneux, Baronne de Prailly, Carew Underwood, Maiden's Blush, Golden Dragon, Madame B. Pigny, Belle Paule, J. Delaux, Mrs. Cannell, Val d'Andorre, and Edouard Audiguier. Mr. J. Dyer, gardener to G. H. Parsons, Esq., The Pentlands, Selhurst Road, South Norwood, and Mr. J. Wyatt were accorded second and third prizes. For the Japanese blooms, one variety, Messrs. W. & G. Drover were first with Boule d'Or, very large and handsome; Mr. Doughty, second for Belle Paule, of remarkable size and colour; Mr. Snow taking the third place with Edwin Molyneux.

Classes were also provided for Anemones, Japanese Anemones, Pompon Anemones, Pompons, reflexed and singles, in all of which attractive collections were shown, Messrs. W. & G. Drover taking most of the leading prizes. Messrs. J. Laing & Sons, Forest Hill, were first with a beautiful group of Japanese varieties comprising many novelties, Messrs. Davis & Jones following, but the latter were first with a group of incurved varieties, the plants in good condition, and bearing fine blooms of all the leading varieties. Specimen plants were well exhibited by Messrs. Cherry, Weston, Cooper, and W. Clarke, who won the principal prizes.

Of miscellaneous exhibits there were several classes for Primulas, with special classes for Potatoes and Onions, in which the prizes were provided by Messrs. Sutton & Sons and Mr. Fidler, Realing. Non-competing exhibits were also staged by Messrs. Sutton & Sons (Potatoes), J. Cheal & Sons (Apples and Pears), J. Laing & Son (Apples), and Messrs. Cannell & Sons, who had a tasteful group of

Chrysanthemum blooms, with Zonal Pelargoniums, and Tuberous Begonias.

First-class certificates were awarded for the following Chrysanthemums:—To Messrs. J. Laing & Sons for M. Bernard; to Mr. Packman for Avalanche, Marsa, and Florence Percy, all Japanese; and to Messrs. Davis & Jones for Violet Tomlin, a beautiful incurved, a sport from Princess of Wales.

STREET (SOMERSET).—NOV. 9TH AND 10TH.

THIS, though not on a large scale, was yet an interesting and highly creditable Exhibition. Mr. A. D. Porter, the Honorary Secretary, and a small Committee worked hard to make it a success, and it is to be hoped were not discouraged by a poor attendance consequent upon the bad weather. We have only space for the cut bloom classes. The best twenty-four blooms, twelve Japanese and twelve incurved varieties, were shown by the Right Rev. Lord Hervey, and remarkably good they were. The Japanese varieties were Criterion, Mons. Ardene, Marguerite Marrouh, Golden Dragon, Val d'Andorre, M. J. Laing, Maiden's Blush, La Triomphante, J. Delaux, Madlle. Moulise, and M. J. Tarin; the incurved being Lord Alcester, Lord Wolseley, Golden Empress of India, Jeanne d'Arc, Refulgens, Alfred Salter, Mrs. Shipman, John Salter, Jardin des Plantes, and Empress of India. Mr. J. Mendy was second. In the class for twelve incurved varieties, the first prize was awarded to Mr. W. Palmer (W. Baskett, gardener), Reading, and the second to Mrs. Rees Mogg. These positions were reversed in the next class—that for twelve Japanese varieties—the exhibits in both instances being fairly good. The twelve bunches of Pompons in not less than six varieties, sent by Lord Hervey, were very good both in flowers and foliage, the second prize going to Mr. A. Colson. Groups of plants were well represented, and there was a good display of fruit.

HITCHIN.—NOVEMBER 9TH.

THE third annual Show was held in the Corn Exchange, Hitchin, on the 9th inst., and though the weather was anything but favourable in the morning it cleared up towards the evening, and there was a fair attendance of visitors. The Show, despite the somewhat unfavourable season, was equal to, if not in advance of former years; indeed, it is not saying too much to state that Mr. R. Adams, gardener to G. B. Hodson, Esq., Frogmore Hall, Hertford, staged the best forty-eight incurved and the best forty-eight Japanese that has ever been seen at Hitchin. For forty-eight incurved and for forty-eight Japanese, Mr. R. Adams was first; second, Mr. Springham, gardener to J. H. Tuke, Esq., in the case of forty-eight Japanese; and Mr. J. Kipling, gardener to Lord Lytton, Knebworth, for forty-eight incurved. For twenty-four Japanese, Mr. Anning, gardener to W. S. Brown, Esq., Digswell House, Welwyn, was first (the only exhibitor). For twelve incurved, first Mr. Upchurch, gardener to W. F. Lucas, Esq.; second, Mr. J. Anning; third, Mr. E. Sharp, gardener to W. O. Times, Esq.; fourth (extra), Mr. E. Orsman, gardener to S. Lucas, Esq. For twelve Japanese, first, Mr. E. Orsman; second, Mr. E. Sharp; third, Mr. W. Millard; fourth (extra), Mr. J. Upchurch. For six reflexed, Mr. Kipling was first with good blooms. For six trained specimens in pots, Mr. Springham was first, and Mr. Upchurch second. For three ditto, first, Mr. Millard; second, Mr. E. Orsman; third, Mr. D. Shepherd, gardener to F. Lucas, Esq.

With groups, first Mr. E. Orsman, second Mr. W. Springham, third Mr. G. Harwood, gardener to A. Ransome, Esq.; fourth Mr. Thos. Joiner, gardener to J. Gatward, Esq. For the best specimen plants in the Show Mr. Springham was awarded the silver medal for a nice plant of M. Tarin, beautifully bloomed; Mr. Adams for the best bloom in the Show (Empress of India) silver medal; for the best bloom in the amateurs' class Mr. W. G. P. Clark was awarded a bronze medal for Golden Empress. For nine incurved, distinct, cut blooms (amateurs), Mr. W. G. P. Clark was first with a most creditable lot, the Judges awarding the National Society's certificate; second Mr. E. Cotton. For six incurved, first Mr. W. Abbiss, second Mr. A. E. Halsey. For nine Japanese, first Mr. Clark, second Mr. E. Cotton. For six Japanese, first Mrs. F. A. Wright, second Mr. W. Abbiss, third Mr. A. E. Halsey.

TABLE DECORATIONS.—First, Miss F. D. Lucas, second Miss F. Barker, third Miss Mary Ransome. For three specimens in pots (cottagers), first Mr. W. Hunt. For six cut blooms, first Mr. W. Hunt, second Mr. J. Holton, third J. Saunders. Three cut blooms, first Mr. J. Holton, second Mr. W. Hunt, third Mr. J. Saunders. Six bunches cut flowers, first Mr. J. Saunders.—M.

PUTNEY.—NOVEMBER 13TH AND 14TH.

THE Putney Show is not a large one, but it is invariably attractive and interesting, and this year proved no exception to the rule. As on some former occasions it was held in the Cromwell Hall, which is in close proximity to two railways, and is in every respect a most suitable structure for the purpose. The plants and groups were arranged at the sides and the balconies tastefully decorated, the Show altogether presenting a bright and pleasing appearance, highly creditable to the Secretary, Mr. Moore, and the Committee. Some notes on the principal exhibits and awards are appended.

Four prizes, the first a valuable silver cup, were offered for the best group of Chrysanthemums, not less than twenty varieties. Those in competition were all of fair average merit, Mr. Townsend, Providence Nursery, Putney, being successful in securing the principal prize. His plants were healthy and in good leaf, and the flowers in excellent con-

dition. Mr. Carter, gardener to Miss Parry, Heathside, Wimbledon Common, was a fair second, his plants being good but loosely arranged, similar remarks applying to the third and fourth prize lots of Messrs. Batten, gardener to A. Venables, Esq., Hollywood House, Wimbledon Park, and Burnett, gardener to Captain Fenwick, Tudor Lodge, Wimbledon Common.

Trained plants were noticeable for healthy condition and free blooming. Amongst the most successful exhibitors in the various classes were Messrs. C. Bentley, gardener to H. C. Smith, Esq., The Cedars, Roehampton; J. Bentley, gardener to Sir Thos. Gabriel, Bart., Edgcombe Hall, Wimbledon; H. Elliott, gardener to Mrs. Harrison, Leyden House, Mortlake; and J. Burnett. All these exhibited very creditable specimens. Amongst amateurs the most successful exhibitors of plants were Messrs. W. Oates, 363, Upper Richmond Road, Putney (excellent); H. Richardson, Springfield, Upper Richmond Road; J. Pepper, Eaton Lodge, St. John's Road, and H. Trengrouse, Danehurst, Upper Richmond Road.

Cut blooms were admirably shown in several instances. Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, won with twenty-four incurved—the principal class in this section—his flowers being very neat and fresh. The varieties were as follows:—Back row—Lord Alcester (3), one selected as the best incurved in the show; Queen of England, Golden Empress, Alfred Salter (2), and Empress of India. Middle row:—Prince Alfred, Golden Empress (2), Princess of Wales, Lord Wolseley, Queen of England, Beauty, and Golden Queen. Front row—Mr. Bunn, Lady Hardinge, Mr. Brunlees, Princess Beatrice, Jeanne d'Arc, Jardin des Plantes, Mrs. Heale, and John Salter. Mr. Knowles, gardener to Mrs. Egerton, Solna, Putney, was second, his flowers being bright and fresh if not remarkable for size, a remark that will apply to the third prize lot of Mr. Woodgate, gardener to Lady Wolverton, Warren House, Kingston-on-Thames. Mr. Sullivan again won with twelve blooms—capital examples of Empress of India, Prince Alfred, Queen of England, Lord Alcester, Alfred Salter, Golden Empress, Lord Wolseley, Princess of Wales, Mr. Bunn, Lady Hardinge, Jeanne d'Arc, and John Salter. Mr. J. Barker was the only other competitor, and was placed second. The latter won with six blooms, the varieties being Bronze Queen (exceedingly good), Golden Queen, Empress of India, Lord Alcester, Golden Empress, and Alfred Salter. Mr. Burnett was second, and Mr. Methven, gardener to W. Keiller, Esq., Fernwood, Wimbledon Park, third.

A charming stand from Mr. Sullivan secured him the first prize for six Anemone-flowered varieties, Madame Cabrol, Jean Marty, Marguerite Solleville, Acquisition, Nouvelle Alveole, and Gluck being the varieties represented. Mr. Knowles was second and Mr. Woodgate third.

In the Japanese as in the other classes Mr. Sullivan swept the board of the principal prizes. He was first for twenty-four blooms, showing the following:—Back row—Boule d'Or, (premier Japanese bloom in the Show), Madame Audiguier, Meg Merrilies, Japonais, Mr. Ralph Brocklebank, Edwin Molyneux, Mrs. Chapman, and Criterion. Middle row—Belle Paule, Mons. H. Elliott, L'Or du Japon, Carew Underwood, Fair Maid of Guernsey, L'Adorable, and Madame Baco. Front row—Duchess of Albany, Avalanche, J. Delaux, Wm. Robinson, Mr. H. Cannell, Marguerite Marrouh, Mlle. Lacroix, and Martha Harding. Mr. Hendon, gardener to D. B. Beresford, Esq., Castletown, Wimbledon Common, showed neat blooms for second prize. Mr. Sullivan again won with twelve blooms, Edwin Molyneux, Fair Maid of Guernsey, Madame Audiguier, Boule d'Or, Mr. R. Brocklebank, Marguerite Marrouh, L'Or du Japon, Belle Paule, Madame J. M. Pigny, Criterion, Madame Baco, and M. H. Elliott representing him. Mr. Knowles was second, showing Belle Paule finely, and Mr. Woodgate third. Mr. J. Bentley won with six blooms, staging moderate examples of Marguerite Marrouh, Fair Maid of Guernsey, Golden Dragon, Belle Paule, Madame Lacroix, and Thunberg. Messrs. Woodgate and Burnett took the remaining prizes; Mr. Knowles won with reflexed, Mr. Hendon following. There was only one stand of Pompons, that of Mr. Methven, to which second prize was awarded.

In the single-handed gardeners' classes, Messrs. Dard, gardener to J. Hooker, Esq., Lomond House, Putney; T. Picking, gardener to J. Pullman, Esq., Grove Park, Chiswick, and G. Walker, 12, Lingfield Road, Wimbledon, were the most successful, and the last named, with Mr. Pepper, showed best in the amateurs' classes.

There were several classes for Ferns, table and berried plants, &c., but space will not permit of details being given. It may be noted, however, that in the fruit classes Mr. Batten showed excellent black Grapes and Apples. White Grapes (Muscat of Alexandria) were finely shown by Mr. Luff, gardener to J. F. Schwann, Esq., Oakfield, Wimbledon Common. Amongst other exhibitors of fruit deserving of mention were Messrs. Newell, gardener to Sir E. Saunders, Fairlawn, Wimbledon Common; Campbell, gardener to Dr. Wood, the Priory, Roehampton; J. Bentley; G. Springthorpe, gardener to H. A. Alexander, Esq., Gifford House, Roehampton; and C. Knowles.

TWICKENHAM.—NOVEMBER 13TH AND 14TH.

THERE is always a certain freshness about the Twickenham Exhibitions that is most appreciated by visitors who are familiar with the too prevalent sameness of shows generally. The local horticultural enthusiasm is great, and the exhibits of corresponding merit, amply proving that the support generously accorded by the residents is deserved. Mr. J. J. G. Pugh is a courteous and most attentive Honorary Secretary, his efforts being strongly aided by an energetic Committee.

The season has been an adverse one to some extent, and the entries were in consequence not quite so numerous as on former occasions, but compensation for deficiencies in this respect was obtained from the fact that the quality of the leading exhibits was above the average.

A class was provided for a group of Chrysanthemums arranged in a space of 50 square feet, T. Twining, Esq. (gardener, Mr. J. Parsons), winning first honours with a freely arranged group of well grown plants, the light and dark colours well balanced, but wanting a few more bright tints. The second, from Lady Freake (gardener, Mr. Street), was also an effective group, but a trifle too crowded and high in front. The third, from J. Bigwood, Esq. (gardener, Mr. Waldie), was excellent in many respects, but there were too many white and pale yellow incurved varieties, and had a few bright Japanese been introduced it would have won first easily.

The cut blooms were good in several classes, and especially so in that for twenty-four; twelve incurved and twelve Japanese. W. Furze, Esq., Teddington (gardener, Mr. Coombs), was adjudged first honours for handsome examples of the following varieties, the incurved being particularly deep, solid, and clean. Incurved—Back row—Queen of England, Golden Empress of India, Empress of India, Lord Alcester. Middle row—Bronze Queen, Lord Wolseley, and Princess of Wales. Front row—Princess Teck, Mrs. Norman Davis, and John Salter. Japanese—Back row—Boule d'Or, E. Molyneux, Madame Audiguier, and Duchess of Albany. Middle row—Comtesse de Beauregarde, Mdle. Laeroix, Val d'Andorre, and Madame P. Pigny. Front row—Jeanne Délaux, Mr. Garnar, M. J. Laing, and Criterion. J. D. Paul, Esq. (gardener, Mr. Munro), was a good second, having twelve fine Japanese blooms, but he lost some points on the incurved; Mr. Davis was third. Mr. Furze had the best twelve incurved, and Mr. Munro the best twelve Japanese in the open classes, the latter being first in similar local classes. For six incurved of one variety Mr. Furze was first with grand blooms of Queen of England, followed by Mr. Munro with Empress of India, and by Mr. Bishop with Golden Empress of India. In a similar class for Japanese Mr. Munro won first honours for magnificent blooms of Boule d'Or, the finest specimens of the variety we have seen this year. Mr. Furze was second for Edwin Molyneux, and Mr. Bishop third with Madame C. Audiguier. With stands of flowers Mr. G. Filsell and Mr. W. Brown were the prizetakers in the order named, Mr. Brown also winning first prize for a bouquet.

In the fruit classes Messrs. Street, Davis, and Parsons were the prizewinners for black Grapes; Messrs. Davis, Garrod and Lambert for Pears; Messrs. Smith, Fitzwater and Parsons for Apples. The vegetables were numerous and good, Messrs. Stroud, Garrod and Coombs winning with collections.

The non-competing exhibits were excellent as usual. H. Little, Esq., St. Margarets, showed a beautiful group of Cyripediums, especially of *C. Spicerianum*, and *Lycastes*. Mr. Bates, Poulett Lodge Gardens, Twickenham, sent a collection of well grown Chrysanthemum blooms. Messrs. Hooper & Co. had some excellent *Gloxinia* flowers. Messrs. Warren and Walker exhibited *Cyclamens* in fine condition. Mr. Poupart sent a collection of fruit, and Mr. Manns had an exhibit of fruit and vegetables.

ECONOMIC ENTOMOLOGY.

[Presidential address to the Highbury Microscopical Society, by James A. Forster.]

I PROPOSE in the following paper to give, in the simplest language, some few facts and observations illustrating what I would venture to term "Economic Entomology," and which I would describe as the natural history of the insect friends and foes of the gardener and agriculturist.

The importance of the study of Economic Entomology is, I think, very generally much underrated. The entomologist is too often regarded with a sort of mild scorn as a man who pokes about in odd places and who finds his pleasure in childish pursuits, or as an enthusiast wasting his time over very insignificant things and claiming for them a preposterous importance—in fact, as an example of the old adage that "Small things amuse small minds." This, I hold, is not even just to the mere collector, but when applied to a true student of insect life is simply an opinion born of ignorance. Small in size, indeed, are the animals he studies, but their importance in the economy of Nature is very great and the study of their lives a most difficult one, requiring a highly trained observation, unlimited patience, unflagging zeal, and in addition to these, a humble reverence for Nature; for to the arrogant and careless she will never tell her tale or disclose her secrets. To the insect world we owe our most beautiful dresses, famous and much-esteemed food, and some of our loveliest flowers. On the other hand, some of our direst misfortunes have been occasioned by insects, countries have been devastated by them, nations reduced to the verge of starvation, travelling rendered impossible, flocks annihilated. Surely the study of creatures capable of affording us such benefits and of inflicting such miseries cannot in any sense be deemed futile simply because they are, for the most part, small in size and insignificant in appearance. Insignificant are they only to our unaided human eyesight. Bring the microscope to our aid, and away vanishes their insignificance, and they stand out revealed in all their wonder as creatures endowed with a beauty and strength that even the higher branches of the animal kingdom cannot rival.

That the microscope has so furthered our knowledge of, and is so essential to, the study of insect life, I think sufficiently justifies my choice of a subject. I believe the subject is no unimportant factor in one of our greatest national problems—viz., the agricultural question. For, as it is evident that the conditions of agriculture in this

country are undergoing and must undergo great changes, to result, probably, in the giving up of the old methods and the old productions, and the development of dairy farming, and the cultivation, at present neglected, of fruit and other products now largely imported from foreign countries—if this comes about, a national knowledge of insect life as affecting agriculture will become of increasing necessity, for with every new cultivation will come new dangers from our insect enemies. Many an insect at present rare in this country, and of no general or economic interest, may, through the introduction of some new crop or some new method of working the land, suddenly become a most formidable plague, placing the prosperity of the cultivator in the utmost peril. Such dangers can only be met and combated with success by a thorough knowledge of these minute creatures: their lives and habits, their histories, and, above all, their enemies themselves, for the most part insects. The majority of farmers and gardeners regard all insects alike as things to be killed wherever seen, and in carrying out this theory murder some of their best friends, while many of their deadliest foes, from their habit of closely concealing themselves, or from their minute size, escape detection.

(To be continued.)

HARDY FRUIT GARDEN.

SELECTIONS OF FRUIT TREES.—Already the work of planting has commenced, and a very busy season will be experienced by most nurserymen. Orders ought to be sent in at once, or the chances are the supply of many of the best varieties will be exhausted and inferior substitutes be sent instead. As a rule early planting is best, but those who prefer to defer the operation till the spring ought yet to order their trees at once, or disappointment may be the consequence of delay. If the trees are received this autumn they need not necessarily be finally planted at once, but may be laid in "by their heels" till the spring, straw litter, or bracken being banked over the lightly covered roots before severe frosts occur.

APPLES.—Dessert varieties suitable for cordon, pyramidal, or bush training:—Beauty of Bath, Irish Peach, Kerry Pippin, Worcester Pearmain, King of the Pippins, Cox's Orange Pippin, Margil, Adams' Pearmain, Blenheim Pippin, Braddick's Nonpareil, Cornish Aromatic, Fearn's Pippin, Court Pendu Plat, Ross Nonpareil, Ribston Pippin, Lord Burghley, Cockle's Pippin, Claygate Pearmain, Nonpareil, and Sturmer Pippin. Good culinary varieties also arranged somewhat in their order of ripening and suitable for garden culture are Keswick Codlin, Lord Suffield, Stirling Castle, Ecklinville Seedling, Duchess of Oldenburg, Emperor Alexander, Peasgood's Nonesuch, Kentish Pippin, Loddington, Mère de Ménage, Waltham Abbey Seedling, Beauty of Kent, Lady Henniker, Lane's Prince Albert, Warner's King, Tower of Glammis, Minchall Crab, Alfriston, Brabant Bellefleur, Reinette de Canada, Dumelow's Seedling, Winter Margarin, Winter Greening, and Brownlee's Russet. If the trees are required to bear almost at once, or are to be much restricted, they should be on the Paradise stock, but the largest and in the end most profitable are those on the natural or Crab stock. Varieties that succeed well as standards on the Crab stock, and therefore suitable for orchard planting, are Keswick Codlin, Lord Suffield, Lord Grosvenor, Manks Codlin, Loddington, Cox's Pomona, Beauty of Kent, Duchess of Oldenburg, Emperor Alexander, Small's Admirable, Hollow Core, Waltham Abbey Seedling, Grenadier, Ecklinville Seedling, Warner's King, Bedfordshire Foundling, Annie Elizabeth, Lane's Prince Albert, Golden Noble, Hollandbury, Pott's Seedling, Frogmore Prolific, Minchall Crab, Reinette de Canada, London Pippin, New Hawthornden, Hanwell Souring, Bramley's Seedling, Winter Greening, and Dumelow's Seedling or Wellington.

PEARS.—Dessert varieties suitable for wall culture arranged somewhat in their order of ripening:—Beurré Giffard, Jargonelle, Williams' Bon Chrétien, Beurré d'Amanlis, Pitmaston Duchess, Flemish Beauty, British Queen, Beurré Superfin, Fondante d'Automne, Brown Beurré, Louise Bonne of Jersey, Urbaniste, Maréchal de Cour, Marie Louise, Doyenné du Comice, Beurré Diel, Thompson's, Huyshe's Prince Consort, Napoleon, Huyshe's Prince of Wales, Hacon's Incomparable, Winter Nelis, Beurré Bachelier, Jewess, Beurré d'Arenburg, Glou Morceau, Beurré Sterckmans, Josephine de Malines, Easter Beurré, Jean de Witte, Olivier de Serres, and Madame Millet. The following succeed well either as cordons, pyramids, or bush trees clear of but sheltered by garden walls:—Williams' Bon Chrétien, Beurré d'Amanlis, Pitmaston Duchess, Louise Bonne of Jersey, Marie Louise d'Uccle, Doyenné du Comice, Durondeau, Beurré Superfin, Beurré Diel, Flemish Beauty, Duchesse d'Angoulême, Althorpe Crasanne, Beurré Hardy, General Todtleben, Beurré Clairgeau, Autumn Nelis, Bergamotte Esperen, Josephine de Malines, and Huyshe's Victoria. For orchard standards plant Doyenné d'Été, Autumn Bergamot, Lammas, Jargonelle, Williams' Bon Chrétien, Hessel, Windsor, Louise Bonne of Jersey, Beurré de Capiaumont, Fertility, Bishop's Thumb, Jersey Gratioli, Eyewood, Swan's Egg, Aston Town, and Colmar d'Été. All the last named should be on the natural or Pear stock, and this stock is

also most suitable where either large wall trained or pyramid trees are required. The dwarfing or Quince stock should be named when ordering trees that are required to bear quickly and not cover much space or occupy much ground.

PEACHES AND NECTARINES.—These succeed only on very sunny walls. Good Peaches given in their successional order are Early Alexander, Hale's Early, Early Rivers, Rivers' Early York, Dr. Hogg, Grosse Mignonne, Royal George, Bellegarde, Alexandra Noblesse, Barrington, Walburton Admirable, and Sea Eagle. Salwey is the latest of all, but is rarely fit to eat. Nectarines often fail where Peaches succeed well. The following are worthy of a trial, these being given somewhat in their order of ripening:—Advance, Lord Napier, Stanwick Elruge, Balgowan, Elruge, Violette Hative, Humboldt, and Victoria.

APRICOTS.—These also require the shelter and heat of sunny walls, or those of nearly or quite southern aspect, and on some soils they cannot be induced to thrive. The most reliable are Early Moorpark, Large Early Breda, Frogmore Early, Hemskerk, Shipley's, and Moorpark. The last named is the best of all as far as quality is concerned, but is most liable to gumming or sudden disease of branches.

CHERRIES.—The following varieties are suitable for sunny walls:—Knight's Early Black, Early Rivers, Black Tartarian, Elton, May Duke, Governor Wood, and Royal Duke; for cooler sites, Bigarreau, Florence, and Late Duke; and for the coolest positions on north walls, Morello, Kentish, and Late Duke. For orchard standards or as pyramids in the open garden, Early Rivers, Adams' Crown, Elton, Frogmore Bigarreau, Governor Wood, Amber or Kentish Bigarreau, Large French Bigarreau, Late Duke, Bigarreau Napoleon, Black Tartarian, Morello, Kentish, and Flemish.

PLUMS.—For wall culture some of the best are Morocco, Early Orleans, Green Gage, Kirke's, Jefferson's, Reine Claude, Guthrie's Late Green, Transparent Gage, Coe's Golden Drop, and Ickworth Impératrice. The following are suitable for pyramids or standards:—Early Rivers, Early Orleans, the Sultan, Victoria, Gisborne's, Goliath, the Czar, Prince Englebert, Pond's Seedling, Green Gage, Purple Gage, Dry's Seedling, Winesour, and Autumn Compôte.

VARIOUS FRUITS.—Medlars are very prolific, and ripen at a time when there is only a limited variety of fruit available for dessert. They succeed best as half standards, being very difficult to train as pyramids. The Dutch produces the largest fruit, but the Nottingham is the most prolific and best as regards quality. A tree of the Black Mulberry would succeed well on most lawns, and yield large quantities of fruit. It may be grown as a bush or pyramid, but standards are the best in every respect. Of Grapes the common White Sweetwater or Royal Muscadine is the most reliable, and the old Black Cluster also frequently ripens well in sunny positions. In the most favoured southern districts the Black Hamburg and Miller's Burgundy may be tried. Figs also require plenty of sunshine and heat. The hardiest and most prolific are Brown Turkey, Black Ischia, and White Marseilles. The most prolific Quince is known as the Pear-shaped, Portugal being a shy bearer; the fruit, however, are large and excellent in quality.

PLANT HOUSES.

Calceolarias.—Plants in 5 and 6-inch pots may be placed at once into 7 and 8-inch pots, and in these they should make large specimens and flower early in the season. Smaller plants may be repotted as they need root room. It is a mistake to allow them to become pot-bound before placing them into larger pots. Once check them by this cause, and the plants never afterwards grow with the same freedom and vigour. Do not place the plants on dry shelves, but stand them on gravel or ashes; they enjoy standing on material that is cool and moist. These plants are quickly devoured by aphides if grown on a dry open stage. Use for a compost good fibry loam three parts, the other part being composed of sand and leaf soil. To this a little soot may be added, and one-seventh of decayed manure. Press the soil moderately firm into the pots. Remove the small leaves at the base of the plants, so that they can be potted moderately deep. These plants root freely from the stem.

Cinerarias.—The earliest plants are very liable to be attacked by aphides now that they are developing their flower stems and buds. Fumigate gently with tobacco smoke, but be careful that the foliage is dry, but damp the stage and floor of the house before fumigating, as this assists in keeping the smoke towards the bottom of the structure. Give these plants clear sweet water every time supplies are needed. The next plants may be subjected to the same treatment. Place sturdy plants into 5-inch pots for spring flowering, and the latest in 60's for potting on again early in January.

Marguerites.—Give large plants that were lifted a light airy place until they are thoroughly established. They will then flower freely enough if placed in a temperature that ranges about 50° at night. With a little care and attention these plants will flower throughout the winter. Young plants in 5-inch pots for spring flowering should be kept close to the glass in a perfectly cool structure. Keep the shoots pinched to induce the plants to branch freely. Damp and heat are the two greatest enemies these plants have to contend against. If any of the plants are infested with a small grub in the leaves, the only cure is to pick off every infested leaf and burn them.

Double Primulas.—Water these carefully, and keep in a moderately dry atmosphere where the temperature can range from 50° to 55°. It is safer to keep the plants on the dry side than to overwater them. The soil should be kept as near as possible in an intermediate state for moisture. Avoid irregularities in this matter, and damping at the collar will be reduced to a minimum.

Single Varieties.—Those that are growing will thrive in a cool house. They will keep and do better on shelves than on a damp stage. The same care should be exercised in watering as advised for double varieties. Plants in flower should have a temperature of 50° to 55°, according to the weather, in a cool rather moist atmosphere; the flowers are very liable to be injured by damp. On all favourable occasions open the ventilators freely, and apply a little fire heat at the same time.

Fuchsias.—The plants that went to rest first may be pruned and arranged in an early vinery or Peach house ready for starting. Do not water them before they show signs of breaking. The moisture in the atmosphere through syringing the Vines will be ample at first. Give them a little tepid water after they have commenced breaking, and when they have well started into growth shake the old soil from them and repot in fresh. Keep young plants in 60's close to the glass. Do not encourage them to grow, merely keep them moving slowly. If growth is encouraged now they will soon run up tall and weakly, and good well furnished plants afterwards in 5-inch pots cannot be produced.

Cannas.—Remove decaying stems from plants that have been stored away, and keep them dry and at rest for another month. Where decoration is done largely in dwelling houses, and foliage plants are appreciated, Cannas will be found invaluable; they stand well, are quickly increased, as well as restored again to health.

Lantanas.—Keep these in a cool moderately dry place until they are at rest, when water may be withheld for a time. Give them the same treatment in this respect as Fuchsias. Keep young plants rooted in August in a temperature of 50°. If grown close to the glass and the shoots pinched from time to time they will be bushy little plants ready for 5-inch pots early in the new year, and will make useful flowering plants for the conservatory.

THE BEE-KEEPER.

APICULTURAL NOTES.

THE LONG IDEA HIVE.

OUR friend "Lanarkshire" is sure one fault in this hive consists in the combs being parallel to the entrance, which he implies is contrary to Nature. This matter of placing frames I have carefully studied for a long time, as I particularly wished to be sure, and I am positive—allowing of course that I may be mistaken after all—that it does not make the least difference which way the combs run. But there is one fact I have never seen anyone notice—viz., when the bees are left to themselves they never build the front comb to the bottom of the hive, at least in front of the entrance, nor the second comb either, though it is lower than the first; thus the bees naturally provide for that free ventilation so much insisted on by the "right-angled" advocates. It is when the front combs are put to the back, reversing the natural position, that the evils of crossway combs are developed; let them remain in their proper place and no difference will be noted.

WHICH WAY DO BEES NATURALLY BUILD THEIR COMBS?

When guides or foundation are given them they have no choice, but one writer, who professes to be an authority, has been insisting that if bees are left to themselves in a skep without any guides, the floorboard of which is either level or inclined from the back, the bees will always build their combs at right angles to the entrance. He also says, when this is not the case the floorboard will be found inclined from one side to the other. On this basis he argues that right-angled combs are the natural position. Very poor logic this, anyway about. When a hive is tilted up the hive walls are not vertical, and as Nature teaches bees to economise every little space, there is only one way in which they can do it and leave the hive walls parallel with the face of their combs; and the said "authority" must know this, by his reference to the combs being in the direction to the pitch of the floorboard. Now, as a matter of fact, based on careful experiment as well as observations made on some thousands of skeps, if a hive is set perfectly level, with walls perfectly vertical, in a position where the sun can shine equally on three sides, and no guide or starter is given, the bees are just as likely to build their combs in any direction, but if the sun is only suffered to shine on that side the entrance is, then, in nearly every instance, the combs will be built parallel to the

entrance, proving conclusively to me that they really have no choice. But whichever way they build them they always leave a blank space in front of the entrance when left to their own natural instincts.

I am not going to defend the longitudinal hive, further than to say that this matter of placing the combs is not one of its faults. Nor do I see why they cannot be safely taken to the moors and back. The frames in mine are 14 inches wide by 10 $\frac{3}{8}$ deep; those with standard frames I threw out of use, as they were too shallow. These frames, when filled with Heather honey, weigh over 5 lbs. each, and though we always travel downhill at a good trot, I have yet to see the first comb break down, and most of the frames are without bottom bars too.

Our friend "Lanarkshire" seems to imply that they cannot be safely taken to the moors. This I cannot admit for a moment. Perhaps his friend did not know how to pack them up. Certainly they are not fit for a novice to use in migrating his bees; they require more knowledge of bee matter than he is likely to possess. The Stewarton hive, I freely admit, is easier to pack, safer to travel, takes up less room, and is vastly superior to the long form of hive; but even in the best patterns I am not quite satisfied. I want a hive that always stands ready packed for a journey, no matter what may be its strength or condition; then one can take advantage of a distant Bean or Clover field or fruit plantation, as mentioned by our friend, and several times also by myself. When we arrive at this perfection, and agriculturists or horticulturists are educated up to the value of bees as fertilisers, we shall have quite a demand for moving apiaries, simply to secure fertilisation of the various blossoms, and no doubt an apiculturist with a good apiary might receive enough money payment to pay all his expenses of moving. This is dreaming of the future, mind.

IN WHAT PART OF THE HIVE DO BEES STORE THEIR HONEY?

As my bees, except the Punic I have so highly spoken of, failed to gather enough Heather honey for winter food, I have had to give syrup, and this at a time when all the bees were on the alert for robbing. We should think, if they had any reason for placing their stores the most remote from the entrances they would surely do it at this time, particularly when thousands of would-be robbers lay killed under the entrances, in fact one stock most beautifully loop-holed the entrance with propolis to keep them out.

All the bees were clustered to the front in every hive, as the sun shines more on that side—frames, mind, all parallel with the entrance. Well, not one stored their syrup in the back combs; in nearly every instance the front comb was filled and sealed nearly to the bottom, and all worked from the front to the back. This was just what I expected, or was sure they would do.

THE HEATHER SEASON.

This has been a practical failure this year with us here. I am inclined to think our friend "Lanarkshire" has had much better weather for his bees. I am pleased to note he has been trying the "mile away from the Heather," as I recommended last year; and though he does not show that it is better or even as good as close on it, still his report is very favourable, and I trust he will try it again. There was not a really good day during the whole season. When it was fine, with the sun shining, there was a terrible gale; in fact, one day I was watching the bees flying against the wind to the moors, and before they had gone 100 yards I could see thousands drop. This I noted by placing my back to the sun and watching them fly along a high hedge side. Many of these would get chilled and never rise again, which would partly account in the falling off of honey. In fact I must say I never saw bees dwindle more during the Heather season.

WHAT RACE OF BEES IS THE BEST?

I have not decided this important matter yet. If the Punic race scaled their comb as beautifully and were as clean in their

habits as Carniolians, I should certainly give them the preference, though they are very cross-tempered when they have the swarming impulse on. They have always been remarkable workers. Whenever a humble bee can be seen these bees would sure to be in full work carrying in pollen and honey, even if all other bees seemed fast asleep. They are the only bees I have not fed this year, the only ones that got enough for winter, and the only ones that got too much. They dwindled not at the Heather, on which they worked nearly every day, whether the sun shined or not. I am positive they never stole a drop of what they had, as I watched them too closely and should quickly have noted if they entered other hives. On October 1st we had a heavy snowstorm and 12° of frost, which cut down most plants. Since the 14th Michaelmas Daisies have been in bloom with fine warm weather. On these they have worked in a manner that does one good to see them, particularly as I had left them on a crate of my new glass sections, which I trust they will not fail to finish—I am sure they will if it keeps warm.

The next in order are Cyprians crossed with blacks. I have not had any crossed with Carniolians, though I have succeeded this year in crossing two Carniolian queens with Cyprian drones. Crossed Syrians have come well up. Carniolians are very good, and I intend trying to cross them with the Punic race both ways, as I say. I am not decided which is the best, all things considered. Each race has certain good points. Probably we shall retain and use them all, for the same reason we use such a variety of everything else in sheep, cattle, horses, vegetables, fruit, or even flowers.

ARE CYPRIANS SPITEFUL?

In another journal "Amateur Expert" says everyone who has had Cyprians two weeks are convinced that they are practically unmanageable. Two weeks is a very short time. At this age—presuming he had a queen—they would be too young to fly off their combs, and every "expert," amateur or not, knows that it is only the oldest bees in any race that ever do the stinging business. Then he speaks of "everyone who has had Cyprians." Surely he must be either a careless or reckless writer to make such an assertion, as there are hundreds of people who have had Cyprians for years, and who say they are as easy as anything to handle. I have had them two years and Syrians seven years, and I have had twenty stocks of Cyprians this summer; and I must say that handled in a proper way they are about the tamest and easiest of any race to handle. I am quite prepared to admit that they are not fit for nervous people to have, who would first accidentally, of course, give the hive a kick and then drop a frame when he had got it half-way lifted out, &c. The secret way to handle these bees is to give them no jar. If you lift each comb out with bees on and slowly turn it over, first putting it back in the hive before treating the next one, by the time the last one is done you can shake, brush, jar, or do anything with them, and when you have shut them up they are not cross afterwards.

THE EVILS OF POND'S ALIAS "SIMMIN'S" SYSTEM OF QUEEN INTRODUCTION.

All will remember that I have several times pointed out in the Journal, also Mr. Bonner Chambers, F.L.S., has done so, that when queens are introduced on this system the queen introduced is mostly superseded, and that a daughter of hers often, if not invariably, takes her place. Yet in the face of what we have shown to be the truth, and which has never been denied by anyone, "Amateur Expert" has the hardihood to say elsewhere that dealers are sending out Carniolian queens for pure imported, which produce banded workers; and that they are also sending out in the fall virgin queens for fertile ones. Had he been up with the times, and have digested what has been so frequently proclaimed in this Journal, a little reflection and common sense would have told him that the Carniolian queens producing banded workers were daughters of the imported ones introduced and mated in the bee-keeper's own apiary, where perhaps all kinds of the yellow races are

plentiful, and that the reason they are proving drone layers in the fall is because all the drones are gone, so that the young queen could not get fertilised. Many have been loud in recommending the Pond's-Simmins', or Simmins'-Pond's system. Had they only recommended marking the queen first by wing-clipping or otherwise its utter fallacy would have been long ago found out.

Only the other day a dealer told me that in the autumn of 1887 he sent a noted British bee-keeper (who has publicly recommended 'Simmins' system as the safest to follow, and which he declares has never failed in his case) nine queens, each one of which was producing sealed worker brood when he sent her. Every one of these nine queens was stated to be a drone breeder; but rather than have any unpleasantness he sent nine more, each one packed up with her own progeny, and yet the aforesaid consignee reported most of these drone breeders too. The dealer is sure his customer is a swindler, and no doubt the other thinks the dealer is, all because of a faulty system endorsed and recommended by certain of the big authorities (?). Of course I can understand they do not like to acknowledge their mistake, particularly because I first pointed it out, and that I am the author of an absolutely safe method, but they will have to eat their leek in the end. Truth is bound to prevail, and so will perhaps—A HALLAMSHIRE BEE-KEEPER.

THE NEW GLASS SECTION.

SINCE reading "A Hallamshire Bee-keeper's" description of his glass sections in the Journal, I was looking forward with some interest for his further details as to how they are made, fitted with comb foundation, and otherwise made ready for the honey season. If glass and the labour of cutting is so cheap as your correspondent states, and it is correct that bees prefer glass to wood, the sooner we adopt them the better. There is no doubt but that glass is the best material for making the honey look tempting, and I was very much disappointed to find he has not enlightened us any further as to how they are put together ready for the bees. It is easy enough to understand that nothing is necessary when it is full of honey. What we want to know is how they can be fitted together and placed in the racks ready for use in less time than the present wood sections. If he will do this, and take in hand to supply the 4000 pieces of glass necessary to make 1000 sections at a cost of 10s., he will confer a boon on bee-keepers in general and in particular—A SUSSEX AMATEUR.

TRADE CATALOGUES RECEIVED.

John Laing & Sons, Forest Hill, London, S.E.—*Catalogue of Chrysanthemums*.
Little & Ballantyne, Carlisle.—*Catalogue of Trees for 1889*.
Wm Etherington, Swanscombe.—*List of Chrysanthemums*.
Eugène Mézard, Rueil.—*List of Dahlias*.
Thomas Rivers & Son, Sawbridgeworth.—*Catalogues of Fruit Trees and Roses for 1889-90*.

* * * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (W. J.).—Mr. W. Collins, Martinhoe Terrace, Martindale Road, Clapham Park, London, S.W.

Books (Doctor).—The "Parks and Gardens of London" can be had from this office, post free for 2s. 11d. Our reply to your second question is write to Mr. Wm. Paul, Waltham Cross, Herts.

Orchid Holder (A. E. A.).—Your letter is forwarded to Mr. A. Outram, who will perhaps communicate with you on the subject.

Exhibition of Chrysanthemums (Marchal).—It is not possible for us to answer your questions without knowing the conditions attached to the class in the schedule further than to say, if there are no limitation in the class, we fail to see why any variety should be disqualified. In all questions of dispute in exhibiting, schedules should be sent with letters of inquiry.

White Tokay Grape (G. C.).—As you are in possession of the Vine and can compare its characteristics as to growth, leaves, and fruit with the descriptions in Mr. Barron's book, we do not see how you can err in arriving at a decision on the matter. If you like to send adequate samples another year they shall be carefully examined. We are obliged by the notes, and shall be glad to hear from you at any time.

Gilbert's Universal Savoy (Burgess).—It is a little singular that a "reader of the Journal for nearly twenty years" should not have heard of this vegetable before. It has been mentioned dozens of times, and more than once fully described. It was raised by Mr. R. Gilbert, of Burghley Gardens, Stamford, and if you write him he will no doubt be able to give you particulars of its parentage and properties. It is distinct from other Savoy, and very good.

Ventilating Tomato House (Old Subscriber).—Assuming you do not want to commence early by forcing, your proposed method of ventilation will answer. But in addition, and as providing for the contingency of cold winds from the north, we should have large ventilators in the ends of the house in the angle formed by the roof and the top of the wall. A 9-inch wall built with bricks and strong mortar would, we think, suffice; but on this you had better consult a builder, who would perhaps advise a supporting buttress every 5 or 6 yards.

Pruning Vines (Walnest).—The time to prune Vines is directly the foliage has died naturally. Scraping is not advisable, unless they are infested with insects. All that is necessary is the removal of loose bark, any that will come off by rubbing the hand along the cane. This can be done after pruning, and they can also be washed directly afterwards. For years we have used nothing for washing but a solution of softsoap, at the rate of 2 ozs. to a gallon of warm water. Weak solutions of any of the insecticides frequently recommended for the purpose will do equally well.

Seakale (J. B. R.).—If the growths, a foot to 18 inches long, have good crowns, the stems may be cut off, inserted up to the crowns in soil in a dark warm place for forcing; or the plants may be covered with fermenting materials, and after the Kale is cut the stems can be cut down level with the soil. If they had been cut back last spring, and the growths subsequently produced thinned, you would have good crowns now an inch or two above the soil. We should also raise sound young plants from cuttings of the roots; these, if well managed, developing fine crowns for forcing the first season.

Caterpillars and Maggots (Inquirer).—If you remove the surface soil from your Rose bed, give a good dressing of lime, then add fresh soil, surfacing with manure, it will probably diminish the number of caterpillars next year and in other respects benefit the Roses. Dusting the leaves when wet with hellebore powder or making a decoction by pouring boiling water on 2 ozs. of the powder, then adding enough water for a gallon, and with that syringing the trees, will rid them of caterpillars if the work is well done. We should also treat the soil round the Plum trees that are attacked with maggots in the same way as advised for the Rose bed. Tar should not be in contact with the stems of the trees.

Name of Insect (J. Hiam).—The specimen sent is a species of *Sirex*, allied to our British *Sirex gigas*, and belongs to the Hymenopterous order of insects. This group are sometimes called tree wasps, but they have no power of stinging, nor do they make nests. They fly about by day, making a loud humming noise, and occasionally visit flowers. By means of the ovipositor with which the extremity of the body is furnished, the female drives her eggs beneath the bark of some tree, branch or shoot, and the larvæ feed within till they attain maturity, generally assuming the pupa condition in the same spot. Their pupatory life often lasts for years, but in the winged state they seldom live more than a few weeks.

Chrysanthemum Amy Furze (F. W. J.).—In the National Chrysanthemum Society's Catalogue Amy Furze is classed as a Japanese reflexed variety; it is, therefore, admissible in both Japanese and Japanese reflexed classes, but not in those for reflexed only. This, of course, applies to the National Society's Shows, and to the exhibitions of all affiliated societies, but in all other cases, in the absence of any stipulation in the schedule it is purely a matter for the judges to decide whether it is in its true class or not, and the character of the bloom would determine this to some extent. It would be far preferable, however, if the National Catalogue decision were accepted in all cases of dispute.

Lapageria Failing (Bm Accord).—As you attribute the deterioration of your splendid plant to the roots of Elm trees passing under the foundation and impoverishing the soil, lifting and planting again in the same house would obviously be of no avail, as the roots of the trees, if not built out, would take possession of the new soil more quickly than those of the *Lapageria* would. Besides, large plants of this beautiful climber do not "lift" well. We have known some of the finest seriously injured in transplanting though they were in charge

of one of the most successful of cultivators. Your large plant if removed will receive a check from which it will be slow to recover, and it may dwindle and die. Cannot a deep trench be dug outside the house, cutting off all the Elm roots, then making a concrete barrier through which others cannot pass? Some of the soil can be removed from the roots, and fresh added, sprinkling with chemical manure, and mulching to prevent the soil drying would incite the production of surface roots, and then by adequate moisture and occasional applications of clear soot water the plant might be invigorated. We should certainly try the plan before endangering the specimen by transplanting.

Oleander (K. M.).—We have no doubt your plant requires potting. Place it early in the year in a 7-inch pot in a compost of loam, sand and one-seventh of manure. Drain the pot well and press the soil into it firmly. Grow the plant fully exposed to the light to solidify its wood, and the flower buds will then keep on if you pay attention to the supply of water the plant needs. The glutinous substance on your Roses and Myrtle is the result of the presence of insects. On the foliage of the latter sent we found thrips and brown scale. Clear the plants of insects, and the glutinous matter will also disappear. Thrips are destroyed by fumigating with tobacco smoke, so are aphides, or by syringing the plants thoroughly with a solution of tobacco water. To clear off the scale the best plan is to syringe the Myrtle with petroleum and water, use 3 ozs. of the oil to 4 gallons of water. For this purpose you can mix the oil sufficiently by syringing one syringe-full with force into the vessel containing the solution and the next one quickly on to the plant.

The Celery Fly (T. F.).—The leaf-miner also sometimes attacks the Parsnip. Sprinkling the Celery plants with a mixture of petroleum and water, 3 ozs. of the former to 4 gallons of the latter, has been found an efficacious mode of destroying the pest. The mixture is syringed over the plants after the sun has left them in the evening. The fly of the Celery leaf-miner, *Tephritis onopordinis* (fig. 52), has also transparent wings, but with tiny brown patches upon them. The head and body in this species are brownish, eyes dark green. May appears to be the month when it is particularly abundant, though there is a later brood, or possibly two; the maggots growing rapidly when the sun is of average warmth. Towards the autumn a few linger on in the leaves, but most of them descend to the earth before the cold nights of autumn, remaining there as pupæ through the winter months. This maggot or

FIG. 52.—TEPHRITIS ONOPORDINIS.

larva, which is legless, whitish green, blunt at the tail, with sharp retractile head, shows itself by producing blisters upon the Celery leaves. These patches, first white and afterwards brown, are sufficiently visible for children to be employed in pinching the leaves infected, and hundreds or thousands may be thus killed. If the operation, however, is performed carelessly or hastily the plants are likely to be as much injured almost as if the maggots had been left untouched. In some cases the plants are positively killed by this pest, especially where water has been scant and manuring not well attended to, because the new growth does not then replace the leaves that have perished. One of the correspondents of this Journal states that he has found brewers' hops a good preventive. When the Celery seedlings are pricked out he sprinkles some hops amongst them, and at the time the plants are removed to the trenches he puts more between the rows. This seems to keep the flies from approaching to deposit eggs. Also the leaves may be dusted with soot, lime, or other substances which are likely to keep them from settling upon the young plants. The winter is an important season for operations, since many pupæ are lying then in the earth just below the Celery; hence the advantage of scraping off the surface and of rough digging, which buries some too deep for the flies to emerge, and brings others within reach of birds. Or gaslime may be used to give the soil a dressing; this will kill most of the pupæ.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (A. C.).—1, Alfriston; 3, Damelow's Seedling; 4, Evargil; 5, Winter Greening; 6, Cox's Pomona. (S. Taylor).—1, Lemon Pippin; 2, Irish Peach; 3, Ecklinville; 4, Summer Strawberry; 5, Not known; 6, Mère de Ménage. (George Swales).—We cannot identify Warner's Pippin with any recognised variety.

Names of Plants.—We only undertake to name species of plants,

not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (Flora).—The numbers were displaced on some of the specimens. 2, *Cytomium falcatum*; 4, *Adiantum cuneatum*. Of the other two the larger frond is *Polypodium aurum*, the smaller *Nephrolepis tuberosa*.

COVENT GARDEN MARKET.—NOVEMBER 14TH.

MANURE IN AGRICULTURE.

"THE farmers have taken all our sewage sludge, and its effect upon the crops is so satisfactory that we are certain of a ready market and prompt sale for it in future." So said the surveyor of a large town to us recently, and glad indeed were we to hear him say so, for we have long held that the pollution of rivers by town sewage is an extravagant act of folly, and we know that sewage

farming is a very questionable process. Sewage distributed daily in its crude state over any piece of land slowly but surely clogs the pores of the soil, and its effluvia then becomes more and more offensive, sending sickness and disease upon every passing breeze into every habitation within its reach. These facts ought certainly to have weight with the corporations of large towns and cause them to hesitate before taking up any costly sewage scheme rashly.

A general adoption of some method of sewage precipitation is inevitable, by means of which it becomes deodorised, the effluent passing from it free of all foul taint or scent, and all its precious fertility being retained in the sludge. Apart from any sanitary consideration, the high commercial value of the concentrated fertility of sewage commends the matter strongly to general attention. The best form in which such "native guano" has come into our hands was in that of a dry powder manufactured by the International Water and Sewage Purification Company at their works at Acton. This powder is inodorous, of light weight, and therefore very portable and easy of application to the soil. Applied to Barley with the mixture of nitrogenous and mineral manures we used this season, its effect was to increase the bulk of straw and yield of grain materially. But it was upon root crops that it told best. Used side by side with a heavy dressing of farmyard manure for Mangolds it held its own admirably, and with Swedes the crop was altogether superior to that from farmyard manure. If this very excellent form of precipitated sewage can be so prepared and sold to the farmer at a low rate the sewage problem is practically solved. Before all things we would advise the Company to strive for two things, and these are to render the ratio of fertility to bulk as high as possible, and to be content with a low margin of profit at the outset. Once get such a manure thoroughly established in home commerce as a prime fertiliser of the soil, and an increasing profit would be found in a growing demand.

But, alas! the introduction of a new manurial agent is a slow and difficult undertaking. No matter how disinterested one may be, how pure and effective the manure, how clear and unmistakeable the results, ignorance and prejudice combine to hinder that which is so clearly desirable for the common good. Among other reasons for this foolish opposition the adulteration of artificial manures specially mixed for certain crops is certainly one of the chief causes, yet it has been proved to demonstration repeatedly that without a systematic and intelligent application of manure farming does not answer: with it, it undoubtedly continues to answer, and although we cannot hope for a return of the exceptional high prices of the "good times," yet we know that with sound practice a fair margin of profit may still be had. Lying upon our table as we write there are two bunches of Wheat ears, each bunch being a fair sample of the crop in the field from which it was taken. One bunch consists of puny ears much undersized—just so many meagre starvelings. We rub out the grain from one ear and find the number to be exactly twenty-four. Turning to the other bunch we have fine bold ears, all fair examples of really well grown corn, and one ear affords fifty-seven fine bold grains as superior to the others in size as in quantity. We quote this as a fair example of the wide difference there is between high and low farming; but the lesson has a much higher significance, for it clearly illustrates the cause of failure and success. To have a full and profitable crop of Wheat we must first have cleanliness, drainage, and mechanical division, then by a judicious use of manure, timely culture, and the use of pure carefully selected seed, the requisite crown and finish is given to our work.

We were led to write this article by reading an interesting account of a new sewage scheme for Manchester in *Bell's Weekly Messenger*. The Corporation of that town purpose spending £490,000 upon this important undertaking, the most interesting feature of which to farmers are two large intercepting sewers, and the chemical precipitation of the sewage, which under the existing

system finds its way into the Irwell by numerous drains and streams. The sludge obtained by the process of precipitation is to be offered to farmers at the rate of about 25 tons daily. It is supposed there will be a ready sale, because in Leeds the demand for the sludge is greater than the supply. The sludge requires no preparation for use by the farmer, it comes to his hands ready for the land at a price which appears to induce everyone who can get the sludge to give it a trial.

WORK ON THE HOME FARM.

Excellent work is being done on the land now, ploughing and sowing being pushed on, and every effort made to bring up the heavy arrears of such work as closely as possible by the end of this month. So far the Wheat plant that is visible is quite satisfactory, and we are glad to find germination in the seed Wheat quite up to the average. The general prevalence of cold wet weather while the Wheat was in flower induced many farmers to fear that full development of the grain could not follow, but by careful cleaning there is no difficulty in obtaining really good seed. The chief difficulty so far has been in sowing in really well, for much heavy land becomes saturated with moisture near the surface after a few days' steady rain, so that when the weather becomes fine again it is only by a free use of the harrows before and after the drilling that we can get the seed well covered.

Pigs have been altogether withdrawn from the stubbles, and are now closely confined to the yards. We have more pigs than is usual at this season of the year in order to turn all inferior Barley to best account by using it for them. We altogether prefer large warm sheds to single sties or pens for pigs, for with plenty of dry clean straw, wholesome food, and a yard for gentle exercise, they thrive and run very little risk of disease. It is undoubtedly because they are kept in small dirty sties and are allowed to consume much foul garbage that there are such heavy losses from swine fever. We may be told that in order to turn pigs to full account they must be used to make manure, and this fact of necessity involves having some filth in the yards. But if due care is taken to use fresh litter sufficiently often no harm to the pigs need arise from it.

Lambs entering the hogget stage require special care just now, and they should be withdrawn from low damp pasture and sodden heavy land. They require change, and answer best when folded upon Turnips or Mustard by night, and are let run upon sound pasture by day. The high value of sheep as an adjunct to corn farming has induced farmers to give more attention to having a fair proportion of pasture of some sort or other for them.

OUR LETTER BOX.

Treatment of Poor Pasture (A. B.).—The poor weedy pasture should be ploughed now, and next spring by the repeated use of plough and harrows, weeds and grass should be all got out of the soil, collected in heaps, and burnt. How early this can be done will depend upon the weather. The frequent stirring of the soil to clear off the weeds will impart the deep fine tilth to it which it is so important to have in a seed bed for the Grasses of permanent pasture. As soon as the soil has thus been made ready for the seed sow the following mixture:—Perennial Rye Grass, 10 lbs.; Cocksfoot, 7 lbs.; Timothy, 3 lbs.; Tall Fescue, 3 lbs.; Meadow Fescue, 3 lbs.; Crested Dogtail, 2 lbs.; and 1 lb. of each of Sheep's Fescue, Rough Meadow Fescue, Hard Fescue, Milfoil, Perennial Red Clover, White Dutch Clover, Alsike, and Cow Grass. If required a crop of Oats may be taken with the seeds, but as your sole object appears to have good pasture as soon as possible do not sow Oats. If the soil is poor apply with the seed 1 cwt. of nitrate of soda, and $\frac{1}{2}$ cwt. each of steamed bone flour and mineral superphosphate.

REMARKS.

- 4th.—Morning generally bright, afternoon dull with one or two faint gleams of sun, shower in evening.
 5th.—Dull and foggy early, bright day, drizzly evening, gale at night.
 6th.—Fresh cold day without sun-shine, gale at night.
 7th.—Cloudy and cold.
 8th.—Dull cold day, rain at night.
 9th.—Wet till 11 A.M., then overcast.
 10th.—Fine bright day, rain at night.
 Cooler, damp, and generally overcast.—G. J. SYMONS.

DISAPPOINTMENTS.

NOVEMBER is a month in which many cultivators are rewarded for the productions of their skill as placed in competition at public exhibitions. These comprise Chrysanthemums mainly, yet by no means exclusively, for many other plants, such as those grown for table decoration as well as for furnishing conservatories effectively, are awarded prizes at autumn shows, while a great number of awards are made for various kinds of fruit and vegetables. But although the rewards are numerous, and in the vast majority of cases well deserved, yet the disappointments are immeasurably greater in number, for the sufficient reason that there are far more blanks than prizes in public exhibitions, and the greater and closer the competition, the greater the number of contentents who must perforce fail to get into the charmed circle of prizewinners. It is not in human nature to be joyous in the moment of defeat, but most of those who sustain it accept the fact manfully, note the points of superiority against them, recognise the deficiencies in their own produce, and resolve to overcome them and to win next time. That is a spirit which all admire, and no men are more popular at shows than those who win the reputation of being good losers; and then, when these win, as they are sure to do sooner or later, if skilful and persevering, they receive the heartiest of congratulations on their triumphs. Some exhibitors there are who cannot brook defeat, and can never feel they have deserved it, though the fact may stand out bold and clear to unprejudiced on-lookers who are capable of arriving at a just decision on the matter.

At most shows there is a disposition on the part of the losers of prizes to accept with dignity the verdicts of the judges, though there are occasionally exceptions. These are fewer than formerly, due, probably, to a becoming self-restraint in a moment of disappointment, and, it may be, in part to the greater care that is taken by show officials to appoint adjudicators whose experience renders them capable of arriving at just decisions. Undoubtedly it is most important that judges should be competent, independent of all local influences, and careless of all personal consequences resulting from the awards, regarding nothing but their own reputations, that can only be sustained by an unswerving adherence to the high principles of doing what they believe is right in each case. When they do this, and because they do it, they are assailed by disappointed men in the reverse of courteous terms, and by spiteful pettifogging acts they feel that the strongest compliment is paid to them, and their character as adjudicators is the more widely appreciated. The abuse of judges of repute by exhibitors who cannot accept defeat gracefully usually affects prejudicially the latter and not the former.

It is not suggested that the most experienced of adjudicators—men whose verdicts are rarely questioned, except by an occasional bad loser, are incapable of making mistakes—of overlooking a small fault in one thing, and slightly over-estimating a merit in another. If that were so there would be no new trials in judicature, nor verdicts reversed on appeal. The best of judges are liable to err, because they are human; but the greater the special knowledge they possess on the subjects before them, and the greater their field of observation and comparison, with the training of the eye and the mind, resulting from much practice, the less they are liable to be misled into recording wrong decisions; and if

by chance they err, or are thought to have erred, they do not hesitate to re-examine any exhibit when requested to do so by show officials, as the result of a formal and suitable protest in writing from an exhibitor. Protests respectfully made are respectfully entertained, and this fact obviates recourse to the vulgar practice of pestering, not to say abusing, men when engaged in their duties, and who have only one object and desire in view—namely, to do what is strictly fair to all. The unfortunate habit alluded to is much less prevalent than formerly, but is not yet quite extinct.

Judges of recognised standing are fully alive to the responsibilities of their position, and their duties are sufficiently onerous without the worrying they have sometimes to endure from exhibitors who are hunting for honours, which, for whatever reason, cannot be granted. These remarks apply more particularly to what may be fairly termed advertising exhibitors. They bring articles of various kinds to shows, not with the object of adding to the interest of or supporting those shows, but for taking orders, and hence, as far as possible, enriching themselves. To this the judges at the same shows can have no possible objection so long as they are not interfered with, but they object to being followed and solicited with irrepressible importunity for certificates for enhancing the value of their wares. In the majority of cases they have no authority for doing anything of the kind suggested, and in some have no means of knowing the merits of articles exhibited, as these can only be ascertained by comparative experiments extending over a period of months. Judges complain seriously of the present condition of things in the respect indicated; and the time has arrived when the relative positions of enterprising tradesmen at shows, the officials, and the judges should be clearly defined. The former should be told whether or not honours are provided for such exhibits as theirs. If they are, the judges will as readily do their duty as in other classes; if they are not, appeals to adjudicators should cease as out of place, and disappointments on both sides would be averted. A judge at a not unimportant show has made the statement that he was so "pestered" by an advertising showman that he "gave him a certificate to get rid of him." That admission is somewhat startling. The judge defended his action on the ground that he relied on the statement of an authority as to the excellence of the article; but all the same, the right and honest way of registering the honour in question would be, "This certificate was granted to Mr. Cheeky for pestering!"

Stress has been laid on the importance of engaging experienced judges as a means of imparting confidence in the justice of the awards, and hence for reducing possible disappointments to a minimum, as it is a proved fact that losers accept the verdicts of men of national repute better than those of others less known, however competent they may be. Do not let it be understood, however, that the engagement of the "older hands" only is advocated. Nothing of the kind is suggested; on the contrary, it is most desirable that younger men should share in the work, as the supply of men who "know their business" in this matter is by no means in excess of requirements, and there is further the possibility that some of the new men may with a little practice not only equal but surpass the old, and these will then readily stand aside. The great point to secure is efficiency, regardless of age or the particular calling of individuals. Some disappointed mortal occasionally derives comfort in proposing that a particular class of men should not act as judges, but this only seems to increase the engagements of the class they would proscribe. The truth is, exhibitors and show officials have no fads, but search for men who have given evidence of their capacity for doing what is required, and they will continue to do so.

It may, or may not, be desirable to change judges. That is a question for committees to decide. A proved mistake in an important class commonly leads to a change; and in some cases changes are made because a desire is felt to try fresh men without in the least mistrusting the old. Occasionally men not far distant

are chosen, as travelling expenses are less. The plan has answered and has failed; in the latter case cheapness having been bought too dearly. Comparatively new judges, especially if of nervous temperament, are much more comfortable if they have an old hand and cool head to assist them, alliances of that nature usually answering very well, the steadying element being advantageous.

As disappointments are plentiful at the present time, and as the majority of them have arisen through the verdicts at shows, not necessarily wrong verdicts, and as the subject is uppermost in the minds of a large body of persons interested in exhibitions, these remarks may not, perchance, be entirely unseasonable.

ON LILY CULTURE.

"M. M.," page 424 of your Journal, complains that as regards his experience in the culture of *L. auratum*, some were potted for conservatory decoration five or six years ago, others were planted out in the bed of a greenhouse, others planted in various parts in the open ground, and in almost every instance the bulbs have degenerated. I fear that this is a common experience. Our knowledge of the conditions necessary to the good growth of Lilies is yet but in its infancy. I have grown Lilies by hundreds, perhaps thousands, every year for the last eighteen years, and it is only by accident that I now know how *L. auratum* can be grown. I am speaking solely of out-of-door culture; but if that which is the hardest can be attained, then the culture, which is the easier under glass, may be made more simple. I think in the first place that growers in general do not recognise the requirements of Lilies, which are, A, to flower and bloom well in the current year; B, to make new growth and a good sound bulb for the future season's flowering. Unless the second condition is attained then you have a weak growth next season with either a poor flower or none at all—degeneration as "M. M." observes; and I much fear that in planting Lily bulbs the conditions necessary for B are not generally recognised and considered. I will endeavour to explain what my experience on this head has taught me.

1, Very few Lilies like scorching sunshine; they prefer a partial shade to protect their roots but to rear their flower heads into sunshine, while the lower leaves and roots are concealed by surrounding herbage. This is the natural wild condition of many Lilies. Therefore an eastern or western aspect is preferable to a southern one.

2, Lilies like moisture at their roots, and this, as a rule, is sparingly given. Out of the eighteen years in which I have grown Lilies, this season and one other very rainy season about twelve years ago were the very best I have known for Lily growth. The bulbs turned up at the end of the season large, firm, and with splendid new growths. The ground this year in which I have seen *auratum*, *eximium*, *Wallacei*, and *Martagon* growing splendidly is a heavy loamy soil completely saturated and water-logged all the summer—the last place one would choose for growing Lilies; yet in that stiff saturated soil—situate it is true on the slope of a slight hill, and with a gravel bed 3 feet underneath, through which the water flows—small offsets the size of nuts, and Walnuts, planted two years back, have been taken up this year hard sound bulbs as big as a small Orange, and larger bulbs planted one, two, or three years back in equally good condition, only larger in size. I believe water does not hurt Lilies growing out of doors, though supplied in any quantity, but is beneficial. Such at least is my experience.

3, Deep planting should be practised. These *auratum* bulbs are planted from 12 to 15 inches deep, so that except in very dry seasons their roots can always revel in moisture. Before I tried (by accident) this most unlikely soil I lost hundreds of *auratum* yearly by sunstroke, and I found on examination the base of the bulb generally rotten, and nothing but stem roots alive. Under such circumstances no fresh bulb growth could be made, and a hot sun scorched the inadequately nourished foliage.

4, It must be remembered that imported bulbs bring with them fungus germs, which in past times used to destroy case after case of shipped bulbs. This was partially put a stop to by packing each bulb in mud, then hermetically sealing them. I believe I was the first to suggest this plan. In this way, now that the bulbs are more carefully grown and brought to the port to be packed, they come over in much better order; yet out of these a certain percentage contains these deadly germs, which develop during the spring and destroy the inside growth with the power of reproduction, hence every grower must expect a certain percentage of deaths. This generally takes place in June, when warm sunshine proves too much for the plants. Summary.—My experience, therefore, teaches me that, as a rule, Lilies should be planted deep in a cool sheltered aspect where they can get sunshine for a part of the

day on their flowers in rich, clayey, or loamy soil (I prefer these to peaty soils) well supplied beneath with moisture. I should not hesitate in planting *auratum* bulbs in a ditch or at the edge of a rivulet, and I find that the *longiflorum*, *speciosum*, and *Martagon* tribe do equally well in these soils, and that the *Thunbergianum* section grow into large weighty bulbs.

Locality.—It must be stated that these observations on culture apply to Essex only, where the rainfall is scanty, often only 20 inches in the year, and where the sun is often very scorching; but as I have corresponded with residents in many parts of our island on Lily culture I find that Lilies are grown best generally in Scotland and on the western coasts of England rather than in the central and southern. This, again, strengthens my position that moisture and cool air and a cool moist soil are indispensable to Lily culture. In fact, I may say that where *Iris Kœmpferi hortensis* grows well there will also *L. auratum* thrive planted between the clumps of *Iris*. If "M. M.," and others like him, will try again in the direction indicated by these remarks they will, I think, be able to recite a different experience.—ALEXANDER WALLACE (*Author of "Notes on Lilies and their Culture"*).

ALNWICK SEEDLING AND GROS MAROC GRAPES.

THE dull sunless season that we have had has been the means of showing the former of these two black Grapes to the best advantage. At the exhibitions we have seen it repeatedly in splendid form, realising the most sanguine expectations as to its merits. Its colour—when colour has been conspicuous for its absence generally—has been all that could be desired, and its combination of good qualities renders it one of the best black Grapes in cultivation.

The latter of the above seems also to be slowly but surely growing in popular favour, and deservedly so. As a late black it will compete with any variety known. Its flavour, however, is much better from Christmas onwards, say to the end of April, than it is prior to the time named, unless it be worked on another stock, either the Muscat of Alexandria or Black Hamburgh. Even on its own roots its flavour during the early season is better than some other sorts which are more largely grown; for instance, Gros Colman, "which, by the way, is also much improved by being worked upon the stocks above mentioned."

Mention was made of both the above Grapes in a notice of Nannau Park in these columns last season. It was my pleasure to see them again recently, and I find that Mr. Cooke is extending their culture. A Vine grown on the extension of Alnwick Seedling was carrying from fifty to sixty bunches of capital size, and black as sloes. Gros Maroc was also in splendid condition; abundance of well-formed bunches, and equally well coloured. Those who intend planting new Vines this season will do well to try both, is the opinion of—BRADWEN.

CYCNOCHES CHLOROCHILON.

A SHORT time since several exhibitors brought this peculiar Orchid before the Floral Committee of the Royal Horticultural Society, and it attracted much attention by reason of the singular form of the flowers and their strange colouring. It is not a novelty, but is one of the old varieties which has been almost lost sight of for a number of years, and has been rescued, as it were, from its obscurity by some who can appreciate the remarkable floral structure of Orchids in others besides those simply fitted for decorative purposes. The genus *Cycnoches* is a peculiar one altogether, and comprises some interesting examples of the phenomenon of dimorphism in the flowers, one of which—*Cycnoches Warscewiczii*—has been described and figured in this Journal. *C. chlorochilon* is a native of Demerara, whence it was obtained in 1838 by Messrs. Loddiges of Hackney, and for some years after it became known to cultivators it was a favourite at shows and elsewhere. Mr. B. S. Williams says, "We used formerly to exhibit fine specimens of these plants at the Horticultural Society's Shows at Chiswick, and also at those held in the Regent's Park Botanic Gardens, and they were greatly admired on account of their grotesque formation and their conspicuous flowers." *C. chlorochilon* has stout conical pseudo-bulbs bearing

the flowers at the top in pairs, the sepals and petals bright green, the lip broad and yellowish with a dark blotch at the base, and directed to the upper portion of the flower. The column is slender, curved, green, and in the position where the lip is usually seen in Orchid flowers. The plant is of strong habit, requiring a compost of peat and sphagnum, with the temperature of the Cattleya house, supplying abundance of water and moderate shade. Flowers of a plant of *C. chlorochilon* recently exhibited are shown of their natural size in the illustration, fig. 54, page 471.

DENDROBIUM WARDIANUM.

To grow plants of this Orchid to perfection they should at this time of the year be kept in a house of which the minimum and maximum temperatures are about 40° to 50° respectively, and should be so kept until the buds begin to swell, when they may be taken to a warmer house to open their flowers. Of course during the time the plants are subjected to this cool treatment water must be withheld, but when the flowers are opening a little must be given. In treating *Dendrobium Wardianum* in this manner the flowers will be larger and of finer substance; furthermore, it stops the young growths from pushing till after the flowering season, when they will come much stronger than if allowed to grow at the same time the flowers are expanding.—EN AVANT.

NATIONAL CHRYSANTHEMUM SOCIETY'S CONFERENCE AND SHOW AT SHEFFIELD.

NOVEMBER 16TH AND 17TH.

It was proposed some time since that a Conference of Chrysanthemum growers should be held in conjunction with the National Society's Exhibition at Sheffield, and the idea was carried into effect under direction of Mr. W. K. Woodcock. Mr. Tunnington of Liverpool and Mr. E. Molyneux of Bishops Waltham were invited to contribute papers as a basis for discussion, and both most willingly complied, the former choosing as a title for his subject "A Chat about Chrysanthemums," and the latter "The Influence of Wood Ripening on Buds and Blooms." Mr. John Wright was unanimously desired to take the chair, and the Conference was opened at 6.30 P.M. on Friday last in one of the large rooms in the Maunche Hotel. The room was crowded, amongst those present being Messrs. R. Ballantine, William Holmes, W. Tunnington, E. Molyneux, W. K. Woodcock, George Gordon, Lewis Castle, W. Bardney, R. Falconer Jameson, E. Harland (of Hull), J. Udale, and G. Harris (Alnwick). After a few introductory remarks by the Chairman, in which he commented on the valuable services rendered by Mr. Tunnington in promoting the culture of the Chrysanthemum, the latter proceeded to read the following paper:—

A CHAT ABOUT CHRYSANTHEMUMS.

MANY years ago, probably near upon a quarter of a century, the Chrysanthemum was a favourite flower in the neighbourhood of Liverpool. About that time the late Mr. Broome of the Inner Temple Gardens paid us a visit, and brought with him trained plants of *Cedo Nulli* to show Liverpool growers how plant-growing, or more correctly speaking perhaps, how the training of the Chrysanthemum was carried out in the south. For this the then existing Society presented him with a handsome walking stick. We have had several teachers, if I may so term them, for although they may not have actually taught us very much, they inspired Liverpool growers with a determination to excel in the culture of this particular flower. If my memory serves me right, Mr. Hobbs of Bristol next came upon the scene with small but neatly dressed flowers. In this respect they surpassed those grown with us, but we had size on our side, a feature that has characterised Liverpool flowers even up to the present time. I have said the Bristol flowers surpassed Liverpool flowers in neatness, for dressing was not then practised by us. The very same character marked the flowers contributed at a later date (about seventeen years ago) by Mr. Rowe of Roehampton. At this particular time I had to be content with a third place with large but undressed flowers. As I could see dressing was an essential that could no longer be ignored if the post of honour was to be gained, so I set about the manufacture of my own tools; they are rough examples in comparison to what are used by growers at the present time, but they answered my purpose, and I still use them. About this time the late Mr. Hignett and Mr. John Wilson of Sandfield Park were the foremost trained plant growers, and the late Mr. Wm. Briggs, also of Sandfield Park, was the first to show trained plants of Japanese at the Liverpool Show. Plant-training steadily improved, and here I intend to leave them, having only referred to the Japanese for the purpose of showing that no progress was made in the culture of this class before 1878. They were never exhibited as cut flowers until that year, when I staged a box of eighteen varieties that seems to have attracted particular attention.

But during all these years considerable attention was devoted to the

incurved section, and every exertion seems to have been put forward by growers to secure a leading position and keep it. Steady, but sure, had been the progress made in the culture of the Chrysanthemum (especially the incurved). Since then we have marched forward at a very rapid rate. The few incidents that took place ten years ago stirred up growers all over the country. We can only perceive what rapid progress has been made when we contrast the number of growers then and now, the number of Chrysanthemum exhibitions and the money offered then and at the present time, and the difference between the flowers staged then in various parts of the country and the perfection in which they are staged now.

Before passing to the few cultural details I intend troubling you with, I may be permitted to briefly note the cause that largely brought about such a revolution in the culture of this favourite autumn flower. In 1878 ten guineas were collected from those interested in the neighbourhood of Liverpool, and offered in three prizes for twenty-four incurved blooms as an inducement to our southern friends to compete against us. This really was the outcome of a discussion of the merits of the two growers, north and south. But time prevents me touching farther on that matter; suffice it to say, this offer only brought one competitor from the south, and if I may be permitted to class it as a representative one, it displayed a more marked difference than I anticipated would be the case between northern and southern growers. The flowers were very similar to those staged years before by Messrs. Hobbs & Rowe, while Liverpool flowers had increased in size and vastly improved in neatness. The spirit of rivalry that had been created could not stop; it is well it did not. It brought about the Chrysanthemum tournament induced by the liberal challenge trophy that was presented by the President of the Kingston-on-Thames Society in 1879. Though I had grown Japanese for many years this was my first attempt for competition. At that time I may fairly claim for the north the foremost position for incurved flowers, and at the same time admit our southern friends were ahead of us with Japanese, simply because they possessed the best varieties. Great progress has been made in Liverpool, and even greater progress, perhaps, in the neighbourhood of many northern provincial towns. I do not doubt that the same marked progress has taken place in the south. I cannot help thinking that growers were not in real earnest prior to 1878, except perhaps in their own immediate neighbourhood. The bold stand of the south, and the even bolder stand of the north about that period, seems to my mind to have fanned the flagging enthusiasm of growers to do their utmost to gain the victory in the friendly struggle that was to be waged between their respective growers. My successful journey from home encouraged others, and in the following year several ventured from home for the first time, and the result has been wonderful progress in Chrysanthemum growing in the immediate vicinity, at least of many large centres in the northern provinces—in fact all over the country. I shall now give a few details of northern culture; or, perhaps, more correctly, my own views and practice that I have found to result satisfactorily.

I shall not waste your time by minutely detailing how the plants should be treated after flowering; suffice it to say they should be placed in a light position near the glass in a cool airy structure to induce the production of strong sturdy cuttings.

THE BEST TIME TO STRIKE CUTTINGS.

This is a point on which a variety of opinions exist. My experience has led me to divide the plants into two sections, and treat them differently. In this matter I have found that Japanese require a longer season of growth than the incurved section, except a few varieties such as Barbara, Eve, Mabel Ward, &c., which should be rooted with the Japanese; those we strike in December, and the incurved by the end of January or any time during February. I have always succeeded in obtaining better flowers with broader florets by late than early striking. This applies especially to the Empress and Queen family.

STRIKING THE CUTTINGS.

All the growers about Liverpool do not strike their cuttings on the same principle. Some insert them in cold frames, some place them thickly together in pots and place them on a shelf, and are not particular about them flagging and so on. I make up a slight hotbed in a vinery about to be started, with leaves and a small quantity of manure. Particular care is taken that the heat is only of the gentlest description in order to prevent the cuttings from flagging, and at the same time assist them to root in less than half the time than would be the case by cool treatment. Weak growers are rooted singly in small pots, and also those intended for trained specimens. Others are rooted together in 5 or 6-inch pots. By the time the plants are rooted

hotbeds are made for them in cold frames of the same description as for rooting them, they are potted singly and plunged. They become established by the time the beds cool down, which avoids checking the young plants. Weak plants, as well as those for trained standards, are potted on and encouraged by a little bottom heat. Under this treatment they gain strength and make rapid progress. The object to be attained is strong but sturdy growth from the time the plants are hardened to cool frame treatment to the time they are placed outside in May. This is achieved by giving abundance of air and the removal of the lights as the season advances when the weather is favourable. The weather must guide the cultivator whether he is to place the plants outside early in May or towards the end of that month. A sheltered spot should be found for them, or a temporary protection should be given to them in case of late frosts or cold cutting winds. Every care, however, must be taken of them at this stage, for they are easily injured. I have seen the leaves blown off them, and plants subjected to such cruel treatment seldom recover.

POTTING.

Before potting is commenced we place in the position the plants are intended to occupy, old boards, 1 yard apart, on which we stand the plants, pot to pot, until July, when they are placed 6 to 9 inches apart, according to the number of shoots that the plants are allowed to carry. The plants are placed in their flowering pots during May as they are turned outside. We have found 9 and 10-inch pots most suitable, and if larger are used two plants may be placed in them with good results. In draining the pots oyster shells are preferred to crocks, whole ones at the base, and for the top they are broken up moderately fine. Over this a good pinch of soot is scattered to keep out worms and act as a stimulant to the plant. In potting, the soil that I shall recommend should be pressed firmly into the pots. When potting is finished room should be left in the pot for at least the addition of 2 inches of soil.

THE SOIL.

We use turf green from the field chopped about the size of an egg. To this is added one 8-inch potful of soot, the same quantity of pounded oyster shells, the same quantity of bonemeal, and a small quantity of leaf mould to each barrowful of sod.

THE MAY BUD.

There appears to be a good deal of misconception about the May bud. In my opinion it is the result of a check or early striking, and I scarcely remember an example of this when the old stools have been eared for and the plants struck at the time suggested. My advice is Avoid this bud. In nine cases out of ten it throws the bud that should appear from the middle of July wrong. If the plants show this tendency help them out of it as quickly as possible by removing the points of the plants, and select three or four shoots to carry one bloom each. In the case of doubtful kinds that occasionally go blind, stop them in May and run up five or six shoots, and when you have secured the right time buds and observe them swelling, thin out the shoots to three or four. If we do not stop them we always run up more shoots than we intend to retain—that is, from the natural break in July. We stop some and grow others without, and then seldom fail to secure a good flower at the time it is wanted.

FEEDING.

We feed very little before the bud is secured. What we are in the habit of using is liquid from the farmyard diluted with water and a little soot dusted on the surface of the soil during showery weather. A few years ago we had in the garden a cesspool, the contents of which liberally diluted with water I found an invaluable food for the Chrysanthemum. To those who have not used it my advice is give it a trial. At one time we had practically only natural liquids, but nowadays we can make liquid from such a variety of special manures, or dust them on the surface of the soil, and most if not all of them are useful for a change.

TAKING THE BUD.

I have said I am a little later than most growers in securing buds. For the incurved I do not care to take them before the last week in August, or the first three weeks in September, though some of the Japanese might be taken earlier. The aim of the cultivator should be to secure them during the latter dates. When plants have been pinched in their earlier stages some of the shoots will show before others, although on the same plant. This can be regulated to a very large extent in July; for instance, if they show early in that month allow them to grow on until the middle of that month. They must then be pushed to make the next growth by clearing out all lateral growths from the axils of the leaves. At this stage examine the remaining shoots on the plant, and if small growths have commenced showing in the axils of the leaves rest

assured that a bud is forming. My plan is to clear out all growths as in the preceding ease, take out the point of the plant, and do for it what it would otherwise do for itself. But if left alone it would come in too late to be of service for showing.

STAKING AND TYING.

This may be passed over, for nearly each cultivator has a slightly different method, and all answer the purpose, as long as the plants are not broken and each shoot is secured separately, so that light and air can reach them on all sides. One other matter of importance is, that we allow all the shoots of our plants to sway loose 18 inches above the tie, which saves many points from breaking. Some say birds will break the shoots if they alight upon them, but in over twenty years I have observed a solitary robin on these plants, and the shoot it rested on did not break. It is mostly caused by wind and rain, when the plants are tied too near the top.

RIPENING THE WOOD.

I do not attach much importance to this; all that I have ever found to be necessary is to stand the plants sufficiently far apart so that light and air can play all round them. The ripening of the wood depends largely upon the time the bud is taken. Ripening commences to take place rapidly after bud formation and the leaves below it have fully expanded. If the buds are taken too early in August the wood in some seasons ripens too much, and the result is a flat flower and a multitude of narrow petals. Over-ripened wood is, in my opinion, the cause of smaller flowers in the south, and narrower petals than we are in the habit of producing.

TOP-DRESSING.

I advised room in the pots for 2 inches of soil, and this space is to be filled up with rich material as a top-dressing for the plants. This is an important matter. It keeps the roots in full activity, and they are therefore capable of taking up food much more freely than they could possibly do if the roots became sluggish. We top-dress to the extent of exceeding the limit of the pot by placing pieces of turf above the rim. The soil when the flowers are expanding should be full of active roots. This keeps the lower foliage in a healthy condition to the last. Here lies the secret of large flowers possessing depth, solidity, and breadth of petal.

AFTER HOUSING.

Now begins one of the most critical periods in the plant's life, and many plants go wrong from the day they are housed. Many a young grower has had all that could be desired in the way of plants, and evil results have followed a continuation of the treatment the plants received outside. The same strong feeding must not be continued for a time. The plants sulk after losing what they delight in—namely, night dews. If bright weather continues, considerably more moisture is evaporated from the foliage, and any failure in making up for these deficiencies will prove detrimental to the plants. Syringe them thoroughly two or three times a day, according to the weather. When they are accustomed to their new quarters we feed again on the same principle as before housing, and continue to do so until the flowers are ready for cutting. We fumigate with tobacco smoke after housing, for neither plants or flowers will thrive if fly exist upon them.

I shall pass over the subject of dressing, for enough has been written about it, in fact sufficient to frighten a young beginner. My advice is grow the flower fully out, as however good the dresser may be he cannot make a good bloom out of a bad one.

KEEPING THE BLOOMS.

After they are expanded, put them into a dark outhouse as dry as possible. Once I had occasion to place some plants in a certain shed, and there was some lime in a corner that was just falling. This I had always thought assisted in keeping them by absorbing the moisture in the atmosphere. The flowers kept three weeks, and were staged in good condition afterwards. I give this for what it is worth, and think it well worth trying. My last advice is, beware of fogs if real success is to be attained, for in one night they will undo the work of the whole season.

Discussion being invited by the Chairman, with an intimation that questions might be asked and opinions freely expressed either for or against propositions advanced, each giving credit to the other for the best of motives, even if opinions differed, as all were engaged in the common object of acquiring knowledge on points in connection with Chrysanthemum culture—

Mr. LEDGER asked if Mr. Tunnington could explain the reason why some plants of the same variety differed in the time of showing crown buds; and why some plants should grow through them, so to say, not

producing crown buds, but pushing on to the terminals. The questioner intimated that the latest plants were struck in January.

Mr. TUNNINGTON replied that if some of the plants were topped in May by nipping out the points, shoots would be certain to be produced showing crown buds at the right time. He suspected the plants were struck too soon, and some of them received a check. The great point was to keep them steadily growing under the best conditions from start to finish.

Mr. BARDNEY said he never knew plants fail to produce crown buds, though they might form at the wrong time, and even not be seen. If they did not appear at all he should conclude the growth was too soft for their formation.

Mr. PARKES, Derby, desired more particulars on the cutting-down system, which he understood was advised by the reader of the paper.

Mr. TUNNINGTON said he neither practised nor advised cutting down as it is generally understood for the production of the finest blooms; topping was a very different thing for assisting the plants when it was seen they were forming buds too soon, while the next might be too late if the plants were allowed to lose time in the first bud formation.

Mr. BARDNEY explained that in topping, as practised by Mr. Tunnington, shoots differing in length resulted, and buds were formed at different times, those that were right being set, the others regarded as surplus and removed for concentrating the resources of the plant to the development of the blooms.

Mr. FALCONER JAMESON asked if buds did not form sometimes that were too small to be set or taken?

Mr. TUNNINGTON answered that might be so, but in such a case he thought the plants must be weak, and the best plan would be to take out the point and push them on to the next bud, and time would be gained, not lost, by the pinching.

Mr. PARKES wished to have more information about "feeding" before the buds formed, as he did not see how to gain strength of plant without the use of stimulants sooner than was advised. Mr. Ledger also said he found it necessary to apply stimulants before the final potting.

Mr. TUNNINGTON in reply reminded the first named inquirer of the use of freshly cut turves for potting, and pointed out the steady decay of the grass in the soil afforded the plants all the support they needed till the buds were taken, and Mr. Ledger, he said, raised his plants too soon, and allowed them to get root-bound; if he would strike strong healthy cuttings later and grow the plants without any check he would succeed in his object. Mr. Tunnington further observed that in "taking" the buds it was often desirable to remove the surrounding shoots by degrees, allowing one to extend somewhat for taking the sap and "easing" the bud, or the whole force of a vigorous plant driven into the bud might spoil it or lead to the production of a malformed bloom.

Mr. Tunnington's paper, and his prompt and clear replies to the various questions gave great satisfaction to the meeting.

Mr. E. Molyneux was then desired to read the following paper:—

INFLUENCE OF WOOD RIPENING ON BUDS AND BLOOMS.

THE ripening of the wood of *Chrysanthemums* is a very important matter in the growth of these plants for the production of high-class blooms; indeed, without perfectly ripened wood it is impossible to have blooms of the finest quality in all respects. Let it be understood that what I mean by perfectly ripened wood, is wood that is ripened sufficiently by natural means as the result of correct treatment throughout. Sun is essential for the maturation of plants in all stages of their growth; but in some seasons and districts there may be too much of it, and in others not enough, and we must make the best of both circumstances. Wood-ripening does not consist in merely hardening the wood, but storing it with nutriment for the blooms. Forcing the ripening, so to say, by drought or in other ways, contracts the sap vessels unduly, impeding the free flow of nourishment for the blooms at a critical time, and those persons who practise such methods in cultivation act erroneously and fail to produce the best blooms.

Seasons vary so much that the locality in which growers reside is a very important factor in the production of good or bad blooms. Circumstances occur over which cultivators have no control, which prevent them showing the ability they may be admitted to possess. They cannot, for instance, excel during a cold wet summer in a low damp district. The higher and drier the locality the harder the wood and the greater the disposition of the plants to set buds prematurely. This is a difficulty some have to contend with, myself among the number. Where buds are persistently formed long before the time we wish to see them much valuable time is lost in the growth of the plants in their various stages during the time the buds are forming. Moreover, high and dry localities predispose to narrow petals, and rather small but solid blooms; while reverse conditions are promotive of broader petals and larger blooms. Where the locality is high the air, although much rain may be registered, is drier than in the lowlands, and it is this dry air that precipitates bud formation that gives so much trouble to some growers. The proper time to "take" buds of some varieties is

upset altogether under such conditions. They form either too early or too late for producing the finest blooms.

Then the question of dew is important. During a hot and dry summer, as in 1887, the absence of dews in high-lying districts is much felt. Dew invigorates, and its scarcity or absence has been the cause of many small blooms. We can regulate and control moisture in the soil, but have practically no power over it in the atmosphere. We may do our best and may do some good, but after all the most we can do is but little in providing compensation for what we may consider the shortcomings of Nature.

When the growth of plants is soft and gross, the latter particularly, and the wood pale green instead of brown in colour, a want of ripeness is evident. Such plants produce blooms large in diameter, but they are usually lacking in depth and solidity of the petals. This is more noticeable in the incurved section than in the Japanese family. Blooms which are composed of extra broad florets are seldom if ever as solid as medium sized blooms having narrower petals; neither can the former be considered of such high quality as those deeper in build and consequently more firm and more likely to stand fresh a longer time. Blooms having unusually broad florets often show decided roughness and irregularity, and the dresser is not able to present such blooms in the same highly finished condition as when the petals are narrower and the blooms more solid.

The present season is considered to have been a bad one for the growth of large high class blooms, especially in the incurved section. This is borne out by the examples which have been staged at various exhibitions. It cannot be said they have been of the highest quality, or as they have been shown in some past seasons. Some stands have been extra heavy in the size of the blooms, owing to the immense breadth of their florets, but many of the blooms lacked depth in proportion with diameter, consequently they were not so solid as they would have been had the blooms been deeper in proportion to their breadth. After a summer like the past one, we expect to see large blooms which lack solidity and closeness of the petals—a condition which is owing mainly to the unripened state of the wood. I am not in favour of extra large blooms of the incurved section, which are only large in one way—diameter, for the reasons stated—they lack depth and solidity. My idea of an incurved bloom is one not great in diameter alone but deep and firm in build, consequently of a better shape. Such blooms are never seen with extra broad petals, but they carry what is known as a good "shoulder," being rather more orange shaped. Such blooms as I have described are the result of perfectly ripened wood and are seldom met with after a season like the past. Where prizes are offered for the premier incurved bloom in a show, this honour generally falls to a specimen of the character indicated, and not to a flower which has merely two points in its favour—extra width of bloom and broadness of florets. Blooms which are generally chosen for this honour are usually remarkable for solidity and high finish, which two latter qualities cannot be obtained from blooms which have extra broad and thin florets. The ripened character of the wood is the all-important factor in the production of blooms of the highest possible standard of excellence, and the complete maturation we seek is obtained, as far as seasons allow, by careful treatment from the beginning.

The method of culture I advise as the most likely to obtain the desired end is that of growing the plants from the first stage on to the culminating point in a regular steady manner, not by starts and stops such as applying water regularly for a time, then neglecting the plants for a few days. Regular attention to potting is important, or before they become so root-bound many roots must be broken in the process, causing a check to the steady progressive growth that is so desirable in plants for producing the finest blooms. Crowding the plants in their younger stages of growth is most hurtful, and antagonistic to the development of vigorous wood and foliage. Sufficient space should always be allowed the plants. When in their summer quarters they should be arranged in an open position where the sun can shine directly on them, but the position should be protected from north, east, and south-westerly winds, which are often so destructive early in the season when the plants are first placed out of doors. Many plants have been so injured by a loss of their lower leaves during May, that they have never recovered the desired strength. South-westerly winds, which are prevalent during the end of August and the early part of September, often do much damage to the buds and leaves where the plants are much exposed. The flower buds and their peduncles are at that time so tender that the skin may be much injured by being whipped about, so to speak, that a check occurs to the development of the blooms owing to the tissues being broken, thus checking the full and regular flow of sap.

Some growers set too much store on plants with extra thick stems

and gross green leaves. These are, perhaps, pleasant to look upon during the summer, by the uninitiated, but when the test of good culture comes to be looked for, blooms possessing the desirable characteristics are generally missing. Very exuberant plants produce blooms devoid of solidity and other essentials as a rule.

It is possible to have the plants in some seasons ripened too much in dry localities. The summer of 1887 was a most trying one to contend with in high and dry districts, where not a drop of rain fell for eleven weeks, and scarcely any dew during a greater part of that time. The remedy in this case is that of shading the pots from the sun during the hottest parts of the day, by boards set on edge in front of them, fern, cocoa-nut fibre, or mats. Such means keep the roots in a cooler state than they otherwise would be with the sun shining directly on the pots most of the day. In the absence of shade to the pots the roots on the sunny side are almost sure to be killed, and we all know what that means. Plants in low lying districts invariably produce the broadest florets and the largest but not the best wearing blooms. The advantage of those which are more solid in character is often exemplified when the two kinds have stood two days at a show and borne the heat of crowded rooms. Those which are firm remain so longer than those which are more or less loose. These latter quickly show an "eye," which proves their weakness and non-sustaining form.

Flower buds are generally produced upon plants at a more regular time in the various stages of growth when the plants are steadily, hence properly, ripened than when they are not, except in very high and dry localities, where they ripen their growth too early, causing premature bud formation; this must be counteracted as much as possible, though it cannot always be prevented. Growers in the extreme southern counties often experience too early bud formation, caused by a too early ripening of the wood which their northern brethren are strangers to. This generally occurs with the whole of the Queen family, the plants forming flower buds at times between the end of March and the same time in April, causing a serious interruption in their future growth, and preventing the formation of buds at the time most desirable for the district in which the grower resides.

Mr. BARDNEY opened the proceedings by frankly stating the paper they had just listened to had taken him quite by surprise, for he thought its tone would be in opposition to the Liverpool practice, and that stress would be laid on the necessity of extra ripening or hardening the wood. He had come prepared to oppose any such idea; but he found he had nothing to combat, so he would ask the wood-ripening advocates to be good enough to state the meaning of the term, as he thought there was a little confusion on the subject.

Mr. UDAL said a clear conception of the process of wood-ripening was desirable. Some thought it meant mere hardening; but he thought it meant well fed and not pithy wood. For instance, if Vine wood is pithy the best Grapes do not follow, but for the production of these it must be firm and fortified, and should not the same rule hold good in the Chrysanthemum? The best of growth should be induced. Sheer hardness caused by checks was not ripening; but it must be of good quality, stored with nutriment, and given this it would be found that cuttings struck as late as July would often produce very fine blooms.

Mr. BARDNEY failed to see the analogy between Vines and Chrysanthemums, for these are herbaceous plants, while Vines are not. He believed the growths of Chrysanthemums might be over-ripened or rather over-hardened as in the case of last year, and he did not think some of the very hard wood contained much "quality."

Mr. G. GORDON said he was glad Mr. Molyneux had put in a claim for depth of bloom and solidity, and these essential qualities could not be had from immature growths. Something more than mere size was wanted. He feared the attempts to produce huge Japanese blooms had a tendency to demoralise growers of the incurred, hence much of the coarseness of the present day. Mr. Bardney said that wood should not be ripened (No, no, over-ripened). Very well, that meant starvation—starved wood. He thought the reason why blooms in the south were more solid and refined was the consequence of the sun there rendering the plants more highly matured, at the same time the southern blooms were at one time too small, and he credited Mr. Tunnington with having done good by taking his fine examples to Kingston, as since their southern blooms had been larger, while at the same time many of them retained the old quality and finish, and he believed the better the wood was matured—not starved—the deeper, more solid, and more refined the blooms.

Mr. GARNETT, speaking on wood-ripening, treated the subject philosophically. He referred to the importance of perfect leaves for performing their functions of elaboration of sap and secreting nutrient matter in the stems; therefore, without general vigour of plants good leaves cannot be produced, and, failing these, satisfactory results cannot be expected. With strong, actively working leaves under the influence of sun, the wood was well stored with matter for the support of the blooms, and that was what he thought a chief element in maturation.

Hearty votes of thanks were then proposed to the readers of the

papers, who briefly expressed their thanks, and after the Chairman had reviewed the chief points raised in the course of the discussion, a unanimous vote of thanks was accorded to him for the admirable and impartial manner in which he had performed his duties.

THE EXHIBITION.

THE National Chrysanthemum Society's first provincial Show, was held in conjunction with the Sheffield and West Riding Chrysanthemum Society and the Sheffield and Hallamshire Gardeners' Mutual Improvement Society, in the Corn Exchange of the town named, on Friday and Saturday last. A liberal schedule had been provided with some twenty-three open classes, and it was therefore surprising and disappointing to find that the entries were not so numerous as had been anticipated both by the local and metropolitan societies. Several causes had no doubt operated to check exhibitors, one of considerable importance being the unfavourable season, not only for producing fine blooms but also for keeping them. The consequence was that the southern growers had lost most of their best specimens, while the northern growers, whose plants had felt the effects of the frosts more severely, probably did not feel strong enough to enter the lists with a prospect of satisfactory results. There might also have been an element of fear acting as a deterrent. All were expecting a very severe competition, and each thought he would be courting an ignoble defeat by bringing his blooms to the contest. In any case the Liverpool growers altogether failed to appear, though from the south one exhibitor, Mr. Packman, had sufficient pluck to compete, and staged blooms of a very creditable character. It was a source of regret to many that neither Mr. C. Gibson nor Mr. E. Molyneux exhibited, though both were present; and as regards the first-named, if he had only brought the blooms which he exhibited at Wimbledon on the previous day (Thursday) he would have had a clear course in several classes and added materially to the interest of the Exhibition. It appears that the officials of the National Society had no knowledge of the number of entries until the evening before the Show, when it was too late to communicate with exhibitors, and it is evident that at any future exhibition of this character material alterations must be made in the method of receiving entries.

As a gathering of gardeners and Chrysanthemum growers, however, the meeting proved a remarkable success, for all the principal districts in the North of England were represented, and there was also a large party from the South. The Conference held in the "Maunche Hotel," on the Friday evening, was a marked success, and, as will be seen from the papers read and the discussion elicited, recorded on preceding pages, was of an extremely interesting and instructive character. A general wish was expressed that at all future provincial shows of the National Society arrangements will if possible be made for similar conferences.

The Exhibition was formally opened on Friday at 2 P.M., by Lady Stephenson, who was accompanied by Sir Henry Stephenson and Archdeacon Blakeney, all of whom made brief and appropriate speeches, as also did Mr. William Holmes (Hon. Sec. of the National Society), Mr. R. Ballantine (Vice-President), Messrs. W. K. Woodcock, J. W. Jarvis, and J. W. Newsham, representing the local societies.

The Judges were, for plants, &c., Messrs. T. Garnett and George Gordon; for incurred blooms, Messrs. J. Wright and R. Dean; for Japanese blooms, Messrs. Lewis Castle and J. Udale.

The principal class was that for "the best representative collection of large flowering Chrysanthemums, not more than twelve blooms of any section. The following sections, or any part of them, to be represented—incurred, Japanese, reflexed, Japanese reflexed, large Anemone, and Japanese Anemone, the first two sections to be distinct varieties, the remaining four not less than six varieties in each section, and not more than two flowers of any variety." The prizes were a silver cup, value 15 guineas, and £10 in cash as the first, £6 for the second, and £4 for the third. There were three competitors, and a very unusual circumstance occurred—namely, they were all disqualified for non-compliance with the conditions stated in the schedule, and were then judged the stands on their merits. Mr. Parker had only three varieties of Japanese Anemones; Mr. Packman had two blooms of Madame John Laing in his stand of Japanese reflexed, thus making thirteen varieties or fourteen blooms of Japanese; and Mr. Morton had a bloom in his stand of large Anemones, which was considered to show too much in the style of the Japanese Anemone to be admissible. Having come to this decision the Judges found it a simple matter to determine the relative positions of the exhibitors, the leading honours being accorded to Mr. R. Parker, gardener to J. R. Corbet, Esq., Impney Hall, Droitwich, for fine, fresh, handsome blooms, and including the premier incurved Lord Alcester and the premier Japanese Avalanche, both magnificent blooms of their respective varieties.

Mr. Parker's stand comprised the following blooms. Twelve incurved—Lord Alcester, Queen of England, Empress of India, Lord Wolseley, Alfred Salter, Prince Alfred, Golden Empress, Golden Queen of England, John Salter, Jeanne d'Are, Princess of Wales, and Mrs. Heale. Twelve Japanese—Baronne de Prilly, Edwin Molyneux, Madame C. Audiguier, Avalanche, Boule d'Or, Meg Merrilics, Ralph Brocklebank, grand; Val d'Andorre, J. Délaux, Golden Dragon, fine; Madame J. Laing, and Thunberg. Twelve Japanese reflexed—Val d'Andorre, Amy Furze (2), Maiden's Blush (2), Jeanne Délaux (2), Criterion (2), M. J. Laing (2), and L'Adorable. Twelve reflexed—King of Crimsons (2), Irene, Chevalier Domage (2), Cullingfordi (2), Golden Christine (2), Peach Christine, Pink Christine, and Mrs. Forsyth. Twelve large Anemones—Mrs. Pethers (2), Acquisition (2), Fleur de Marie (2), Gluck (2), Empress (2), Lady Margaret (2). Six Japanese

Anemones—Mdlle. Cabrol (2), Fabian de Mediana (2), and Sœur Dorothée Souille (2). Mr. W. Packman, gardener to C. Shea, Esq., Foot's Cray, Kent, was second, his incurved being smaller, but fresh and well finished; in fact his blooms were not so heavy in any section as the first prize stand. The best of the incurved were Mrs. Heale, Jeanne d'Are, and Barbara; Japanese, Avalanche, and Boule d'Or; Japanese reflexed, Criterion, and Jeanne Délaux. Especially good was Jean Marty in the Japanese Anemone stand. Mr. T. B. Morton, Mowden Bridge Nurseries, Darlington, was third. The incurved were small and rough; the Japanese were thin, showing a want of colour in the varieties also. The Japanese Anemones in this stand were very good. The large Anemone stand contained a bloom of a variety which showed decidedly the character of a Japanese Anemone, therefore could not be regarded as belonging to the large-flowered Anemones.

There were no entries in the classes for thirty-six, twenty-four, twelve, or six incurved blooms, a most unaccountable circumstance. For thirty-six Japanese blooms, not less than eighteen varieties, there was only one entry, that from Mr. Parker, which contained capital blooms, the varieties being as follows:—Boule d'Or (2), Baronne de Prailly (3), Comte de Germiny, Meg Merrilies, Madame C. Audignier (2), Ralph Brocklebank (3), Avalanche (2), M. Brunet (2), Japonaise, M. J. M. Pigny, Mdlle. Lacroix (2), Golden Dragon, Edwin Molynex (2), Fair Maid of Guernsey, Jeanne Délaux (3), Martha Harding, Maiden's Blush, Duchess of Albany (2), TLunberg (2), Marguerite Marroucb, Madame Laing, and Fernand Féral. There were no entries in the class for twenty-four Japanese blooms, while in the class for twelve Japanese, distinct varieties, there was only one, Mr. J. R. Leadbetter, gardener to A. Wilson, Esq., Tranby Croft Hall, which was an even and good stand; the varieties being Ralph Brocklebank, Belle Paule, Boule d'Or, Mez Merrilies, Mdlle. Lacroix, Sceptre Toulonsain, Marguerite Marroucb, Soleil Levant, Criterion, Jeanne Délaux, Golden Dragon, and Maiden's Blush.

The classes confined to growers residing within a radius of twenty miles from Sheffield parish church produced a fair number of entries, while the blooms were in most instances of fair quality. For twelve Japanese varieties Mr. W. Redmill, gardener to J. G. Lowood, Esq., Five Oaks, Glossop Road, Sheffield, was first, his best blooms being Baronne de Prailly, Dormillion, and Criterion. Mr. W. Redmill was again first for six Japanese, staging good blooms of Val d'Andorre and Criterion. Mr. J. Walker, gardener to B. P. Bromhead, Esq., Broomhall Field, Sheffield, staged the best band bouquet of Chrysanthemums.

For the best group of Chrysanthemums arranged for effect occupying space not exceeding 81 square feet, a belt of Ferns and other plants allowed as an edging, Mr. J. Redmill was the only competitor with a group very well arranged, but the blooms were of moderate quality only. For six trained specimens (large flowered varieties) Chrysanthemums, Mr. J. Walker was first with small plants of leading varieties. For three trained specimens (Pompons), distinct varieties, Mr. J. Walker again took leading honours with small plants.

In the class for the best group of miscellaneous plants arranged for effect, occupying a space not exceeding 64 square feet, Mr. W. Collier, gardener to John Eaton, Esq., Sbannon Bank, Sbeffield, was first with a light arrangement of suitable plants of Palms, Crotons, &c. its one fault being the pots in front being too freely exposed to view. Mrs. H. Wilson was a close second, her group being rather too green in the front—not enough flowering plants used. Mr. J. Speight, gardener to Mrs. Fawcett, Clark House, Sheffield, was a good third. The best twenty pots of British Ferns were staged by Mr. J. Eadon, Canfield Road, all healthy plants; and Mr. J. Newsham, Covenant Cottage, Meersbrook, was second. The best six Primulas, red or white, double or single, were staged by Mrs. H. Wilson, Westbrook; second, Mr. F. Shorter. Three pots of Selaginellas, distinct, were best staged by Mr. J. Speight, gardener to Mrs. Fawcett, Clark House, Sheffield, with small well grown specimens.

Fruit was not largely shown. The best two bunches of black Grapes were staged by Mr. A. Malcolm, gardener to J. G. Conlshaw, Esq., Taptan Cliffe, Sheffield, shapely bunches of Alicante of good colour. Second, Mr. C. F. Shorter, gardener to R. F. Mosely, Esq., Croft House, Brincliffe. Mr. Malcolm was the only exhibitor of two bunches of white Grapes, showing good examples of Golden Queen.

Non-competing exhibits were noteworthy, especially that from Messrs. H. Cannell & Sons, Swanley, Kent, which contained six boxes of cut blooms of Zonal Pelargoniums of excellent quality, making that part of the hall in which they were staged particularly bright. They also staged several boxes of cut blooms of Chrysanthemums of new and leading varieties. Messrs. Davis & Jones, Lilford Road Chrysanthemum Nurseries, London, had six dozen blooms of new and leading varieties of Chrysanthemums. Messrs. Fisher, Son & Sibray, arranged a central group of plants in the hall, consisting of well grown stove and greenhouse varieties, also cut blooms of greenhouse Rhododendrons, and boxes of Lapageria profusa and Lapageria maculata, the latter new variety having full solid blooms mottled with white; for this a first class certificate was awarded. The same firm also showed plants of their new Yew, Taxus adpressa elegantissima. Mr. S. W. Seagrave, Seagrave Nursery, Gleadless, Sheffield, staged in one corner of the hall a group of plants consisting of Palms, Heaths, Primulas, &c. Messrs. G. Bunyard & Co., The Nurseries, Maidstone, Kent, sent a capital collection of Apples and Pears. The Apples consisted of ten large basketfuls and seventy dishes besides and thirty dishes of Pears, the fruit of excellent quality and highly coloured. Messrs. Miram Shaw & Son, nurserymen, 14, Broad Street Park, Sheffield, staged a capital group of plants, Palms, Crotons, Ferns, &c. neatly arranged.

A first class certificate was awarded to Mr. E. Beckett, The Gardens, Aldenham Park, Herts, for three blooms of Chrysanthemum Sunflower, a magnificent Japanese variety, orange yellow, with long drooping florets.

A luncheon was held in the "Mauneh Hotel" at 3 P.M., attended by Judges, exhibitors, Committee and friends. Deputations from Hull, York, and Leeds subsequently had interviews with Mr. W. Holmes and other officials of the National Society with respect to making arrangements as to the next provincial show, and all appeared equally desirous that the Society should proceed to their respective towns. The matter could not, however, be definitely settled until formal invitations had been received and submitted to the National Society's General Committee.

EVENTS OF THE WEEK.—The Chrysanthemum Shows, which have been so numerous during the past week or two, are now nearly all over, the only two of importance are at Hull to-day (Thursday) and at Pontefract to-morrow (Friday). Messrs. Smail & Co. will hold sales of bulbs and other plants on Monday, November 26th, Wednesday, November 28th, and Friday, November 30th, at 123, Fenchurch Street, E.C.

— HORTICULTURAL CLUB.—The second monthly meeting and dinner of the session was held at the rooms, "Hotel Windsor," Victoria Street, Westminster, S.W., on Tuesday evening. There was a very large attendance of the members. Mr. Harry J. Veitch occupied the chair. There were also present the Reverends W. Wilks, F. H. Gall, and F. R. Burnside; Messrs. A. Moss, T. W. Girdlestone, E. R. West, G. Bunyard, H. J. Pearson, Alfred Pearson, J. Walker, W. B. May, A. F. Barron, R. B. Cater, W. F. Cooling, P. Crowley, W. J. Jefferies, the Hon. Sec., &c., and after dinner a paper was read by Mr. Geo. Bunyard on "November and December Pears." An interesting discussion, in which Messrs. Veitch, Pearson, Barron, and others took part, followed, and a vote of thanks was accorded to Mr. Bunyard, and the Secretary was requested on behalf of the Club to write a letter to Mr. John Lee expressive of their sincere sympathy with him in his serious illness, and expressing the hope that he would soon again be amongst them.

— UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The usual monthly meeting of the above Society was held at the "Caledonian Hotel," Robert Street, Adelphi Terrace, Strand, on Monday evening, November 12th, Mr. J. Wheeler in the chair. Two new members were elected. The Committee are glad to say that the late annual dinner was a decided success, and it was proposed by Mr. Hudson, and seconded by Mr. G. Wheeler, and resolved, "That the best thanks of the meeting be given to Messrs. Laing and Williams for decorating the dining hall with beautiful groups of plants; to Messrs. Cannell, Lowe, and Chard for cut flowers; to Mr. Thomson of Clovenfords and other friends for fruit for dessert; to Miss Belval and friends for their beautiful music and singing; and the Press for their valuable help in giving such an excellent report of the proceedings." The rules may be had for six stamps on application to W. Collins, 9, Martindale Road, Balham, S.W.

— WE regret to hear that Mrs. Jane Maria Laxton, the wife of Mr. Thomas Laxton, died at Bedford on the 17th inst., aged fifty-four.

— IN answer to your correspondent, Mr. Gecson, respecting the quantity of PETROLEUM FOR DESTROYING SCALE ON PEAR TREES, hitherto I have used a wineglassful to a gallon of water, and found it sufficient, but if the trees were badly infested with scale, and required more to kill them, I should not hesitate to use double that quantity without fearing any injury to the bark or buds of the tree thus operated on.—A. PETTIGREW, Cardiff.

— POTATOES AT THE CRYSTAL PALACE SHOW.—Mr. C. Fidler complains of the omission from our report of the above Show of the fact that he was awarded an extra prize for 120 varieties of Potatoes. It is absolutely impossible to record the name of every prizewinner at November shows, and this is so evident to exhibitors as a body that it is seldom any of them make a complaint on the matter.

— I THINK it a pity that that old fashioned flower the VERBENA

is not grown more generally than it is. We have had a border here about 100 feet long filled with mixed varieties. They stood the cold and wet weather wonderfully well, and were much admired. Some of the varieties are very sweet scented, which is a great recommendation. Good strong plants placed out at the end of May produce the best results, weak spindly plants are of little use.—GEORGE COOKE.

—REFERRING to RHODODENDRONS "N. G." observes:—"The dry weather during the spring prevented Rhododendrons making much growth, and the early varieties set abundance of flower buds, but unfortunately they burst into late growth. *R. ponticum* and the majority of the hybrids made a strong second growth, so there is but little prospect of a good display of these flowers next season. *Azalea pontica* and the Ghent varieties, on the other hand, have set well, and the wood was too ripe for them to burst again into growth."

— PINES AT PARKFIELD, HALLOW, NEAR WORCESTER.—In these well managed gardens there is at the present time as good a house of Pines as could be found in any garden. There are about fifty fruiters, the fruits averaging from 8 up to 9 or 10 lbs., and in one case 11 lbs. This latter weight has been exceeded in previous years. The variety is Smooth Cayenne. The house is a sunk span-roof, about 14 feet in width inside measurement. The age of the plants is just eighteen months from the sucker. Mr. Brockington, the gardener in charge, deserves much praise for what is undoubtedly one of the greatest triumphs in Pine culture.

— IN the same garden may be seen one of the finest representative displays of CHRYSANTHEMUMS in the western Midlands. About 700 plants are grown on the large-bloom system. The majority of new varieties, or those that are worthy, are added annually. Mr. Lea, the owner, does not care to exhibit, which is the reason they are not more widely known. The plants are arranged on each side of a large span-roofed house, with a raised platform through the house for inspecting the blooms. In this manner the blooms are just brought below the eye. The neighbourhood of Worcester is getting quite a centre for Chrysanthemum growing in the western Midlands, Impney and Hindlip being in the near neighbourhood, with others cropping up.—A. Y.

ROSE PLANTING.

ALTHOUGH general directions are given in all works upon the cultivation of Roses as to the various processes of cultivation, and each calendar of operations tells all whom it may concern that November is the best time for making, arranging, and altering beds, yet as our seasons vary so much of necessity, the time, and indeed the method, of these processes vary. The season may be very wet or it may be very dry; or frost may interfere with operations, and so instructions suited to each year are not out of place.

With regard to the time of planting, I at one time believed that it might with advantage be deferred until spring, and did so in one or two seasons, when I obtained my plants from the nurseryman, and planted them in the spring. I found that very little root action had taken place, and that when I planted and pruned them they seemed to experience a check; so I gave up the practice. I found that there were so many things to be done in the garden at the same time that Rose-planting was apt to be done hastily, and so I returned to the old orthodox time, and am now preparing for my work, and have indeed partly begun it in a small way.

The season has been a very peculiar one. We had on October 3rd a frost which was general with greater or less severity all through the country. This injured to a great extent the autumnal bloom, but did no harm to the plants, while the remainder of the month was so dry, at least in the southern parts of the kingdom, that planting was an impossibility; just as Wheat sowing was prevented in our neighbourhood, and now very heavy rain has come, so that care will have to be exercised as to the time of planting. Let it not be hurried, for planting may take place at any time during the next two months when the weather is favourable.

There will be two kinds of planting carried on doubtless in most gardens—the removal of plants in the garden itself, and the planting of those received from the nurseryman. With regard to the former the ball is in the amateur's own hands. He can choose his day, take up his plants and replant them without let or hindrance. Not so, however, when he receives plants from the nurseryman; they suit their convenience as to the time of sending them, and he must be prepared to receive

them. Let nothing induce him to unpack his straw bundle in frosty weather. Roses are so well packed nowadays that they will keep for a long time in the package in which they are sent. Another point equally necessary is not to leave the roots exposed for even an hour. My own practice is to unpack the parcel, having a trench dug ready, and then lay the plants in it, covering the roots up well, and then taking them up one or two at a time and planting them where they are permanently to remain.

In planting I never advise manure to be used, however well decayed. It is impossible to prevent it getting to the roots, and when it does it is apt to create fungus. When a hole is made have ready some good well decayed turfy loam, place some of this in the bottom of the hole, take the roots and spread them out carefully, do not injure the bark of the roots; then shovel in some more loam and tread it down well, and place, if the shoots are at all long, a stake to steady them so as to prevent the wind from loosening the plants in the ground and making a hole into which wet falls and injures the roots. These directions refer to the classes of Hybrid Perpetuals and such summer Roses as an amateur may like to grow, and some of them are very beautiful. With regard to Teas practice will vary in different parts of the country. In the south there is but little need to make any difference between them and the Hybrids, but where this is done they are generally laid under a south wall where they can be covered in severe weather and not planted until April. This year I am enlarging my Tea beds and diminishing the number of Hybrid Perpetuals. The former do well with me, and as a rule they are really the Perpetuals, blooming earlier than any others, and continuing in flower later. This year they have not done so well as autumn bloomers; the cold of October 3rd, and the thick foggy weather which followed it, prevented the expanding of their blooms, but as a rule I am able to cut blooms from them in good order far into November.

One subject always exercises Rose-growers at this season, and that is whether it is worth while to get any new Roses, and if so, what are to be depended on? Of course the answer depends much on whether the amateur is disposed to spend a little money or not. If he be the following may well be added:—Earl of Dufferin, a grand high-coloured flower of good quality and vigorous habit, and very sweet in perfume; Sir Rowland Hill, a remarkably coloured flower, quite distinct, of good habit, the colour a rich claret suffused with crimson; Mrs. John Laing, a beautiful pink coloured flower of good substance and shape; Lady Helen Stewart, a high coloured flower of good quality. I would not recommend Grand Mogul until it has been further tried, for from many quarters I hear it is hardly to be distinguished from Jean Souper, a flower sent out some years ago. Gloire de Margottin, bright dazzling scarlet, and very free flowering; Miss Ethel Brownlow is a good Tea of novel colour; Madame Hoste is also a fine yellow Tea; and then there are the two little Polyantha Roses, Golden Fairy and Little Dot, the former bright fawn yellow with lighter margin, the latter white with a salmon centre; they are delightful in every way, but when cultivated in pots they form most charming additions to greenhouse or conservatory.

From all appearances it will be some time before we can get on with planting. Here in Kent we have had recently nearly 2 inches of rain, and it seems more to follow. Under these circumstances planting will be impossible.—D, Deal.

NOTES ON EARLY ENGLISH HORTICULTURE.

(Continued from page 286.)

THE reign of Henry VIII., though certainly not a period of history in which, on the whole, Englishmen can exult, was distinguished by this fact, that it saw the revival of English horticulture, and the re-importation, or introduction, of a great number of foreign plants. These were chiefly fruits, vegetables, and useful or ornamental trees; the garden flowers were few. And it is interesting to note how the botanists and gardeners about this time discovered, by comparison with newly arrived specimens, many plants which had been brought over by the early Crusaders, or still farther back, in the days of the Romans. There had, however, been indications of a coming improvement while Henry VII. reigned. A worthy citizen and haberdasher had published, early in the sixteenth century, his "Chronicle of London," in which, amongst other matters, he discoursed upon the crafts of planting and grafting, the various employments of the seasons, and on a method of his own for growing "perceley," that is, it is supposed, not Parsley, but Cress, in the space of an hour, which seems somewhat marvellous. Lord Cromwell brought into our island several kinds of the Plum about this period. One was the Pendragon, or Perdrigon, of two colours, and much esteemed. Holinshed says that the nobles had a fancy for tree planting, and surrounded their mansions with groves, composed, doubtless, chiefly of our common natives.

The lack of flowers until a later period obliged gardeners to try various expedients to diversify the grounds and please their patrons. So they contrived mounds with spiral ascents, "knots," composed of earth or soils of different colours, mazes, wildernesses, and alleys, or paths set with lines of trees and hedges. By the order of Henry VIII. the Royal gardens of Nonsuch were laid out in a style which made them an object of admiration for centuries, and the

Lilac is mentioned as a novelty. Fruit trees were numerous. The Apriote may have been amongst them, as it was brought over about 1524 by Woolf, gardener to Henry, or as some say, by Mascal. Probably the Nectarine belongs to the same date, but it is not distinguished from varieties of the Peach. Evidently that fruit was freely grown in London gardens before the middle of the century. Mascal is said to have brought over the first Pippins two years later, planting them at Plumpton on the north side of the South Downs. The Golden Pippin, it is supposed, was first reared at Parham Park, also on those downs. Henry's fruiterer, one Richard Haines, is stated to have obtained the Cherry from Flanders and planted them at Sittingbourne, Kent, but we have abundant proof that Cherries were an abundant fruit in England before his time, and in 1540 we read of a Cherry orchard of thirty-two acres, the value of the fruit that year being £1000. But it is likely Haines was introducer of the red Flemish Cherry, as Tusser mentions a red kind as novel, the old English one being black. Though the Quince is attributed to this reign, it had been cultivated before, as one author mentions having seen it planted as a hedge to gardens and vineyards not many years after, which would imply it had been known long enough to become common. The Musk Melon, a native of Tartary, but which came to England through Italy about 1520, Gerard tells us he saw at St. James's Palace and in Lord Sussex's garden near Bermondsey. Next century this was a very favourite fruit, and much cultivated along the banks of the Thames in Surrey.

Turner published a curious book on "Herbes" in 1548 which marks an era in horticultural progress, and records, amongst species of less note, the Sweet Bay, the Spruce Fir, the Cypress, the Pomegranate, the Oriental Plane, the Fig, the Black Mulberry, the Almond, the Stone Pine, Rosemary, Rue, Savine, and Jessamine. To the Almond the attention of gardeners was specially drawn by its habits of early flowering and late fruiting. The latter, they thought, arose from the oily moisture of the species. It is supposed that the original Mulberries were those which Phillips saw at Sion House in 1820 and reported upon. All the timber had crumbled owing to their great age, but the trees were sustained by means of the bark, and they produced both flowers and fruit. Probably there were in England Fig trees, descendants of those which the Romans introduced, though Turner seems to have regarded the species as a novelty, and the White Marseilles variety, certainly planted by Cardinal Pole in 1525, at Lambeth, is commonly said to have started the culture of the Fig once more. A later edition of Turner adds the Walnut, a tree which came slowly into popularity, Rue, Lavender, as arrivals before 1570, and L'Obel at that date mentions doubtful species of Pistacia, Genista, and Cistus. We do not hear of any nursery till after the middle of the sixteenth century, when that of Corbet is mentioned, also called Poynter, at Twickenham. Ben Jonson knew him, and Gerard says he was a most cunning and curious grafter of all manner of rare plants. And the time of trouble that came upon the monasteries put an effectual stop to the monks' quiet pursuits of gardening and illuminating. One of the last notable gardeners of that class was Prior Bolton of Canonbury, at the north of London, who planted many trees in the garden ground there, part of which yet remains open, but the trees have gone, though some were in existence fifty years ago. The worthy old Prior died in 1532.—J. R. S. C.

THE NATIONAL AURICULA AND THE NATIONAL CARNATION AND PICOTEE SOCIETIES.

(SOUTHERN SECTIONS.)

It is related of Sir Walter Raleigh that when he was writing his History of England in the Tower, one day looking out of his window he saw an accident. Two of his friends who had also witnessed it came to see him, and related it; their accounts were so opposite that he threw down his pen in despair, saying how was it possible to write history when even he could get no correct account of a matter that happened under his own eyes? With some such feeling have I read Mr. R. Dean's statement with regard to the annual meeting of the above Societies. I rubbed my eyes, wiped my spectacles, and thought I must be dreaming, but I suppose it's all right, only it's very odd. As Chairman of the meeting I wish simply to state the following facts:—

1, That not only was the proposition of holding the Shows in 1889 in connection with the R.H.S. mooted, but I was told there need be no hurry in approaching the Crystal Palace Company until after the next meeting of the Council, when the matter would be settled. 2, That I, foolishly I suppose, imagined that Mr. R. Dean was strongly in favour of our so doing. The Drill Hall is, indeed, spoken of as undesirable if it could be avoided, but he promised if held at Chiswick that he would provide a conveyance at Ealing to take the boxes from Reading, &c., to Chiswick by road. 3, The general feeling of the Committee was in favour of holding the shows in connection with the R.H.S.

Mr. Dean fears that if the reports of meetings was to be left to the

officials very incorrect reports would be the result; his is, at any rate, a proof that it would not be remedied by leaving it in unofficial hands. The personalities which close Mr. Dean's letter may well be left alone, and I do not think they will injure the person against whom they are directed.—H. HONYWOOD D'OMBRAIN, *Chairman*.

CHRYSANTHEMUMS AT PERRY HILL.

THERE is a fine display of these beautiful autumn flowers at Messrs. Carter's nurseries just now. Three newly erected houses are devoted to the collection, which is a very large one, and includes many of the novel varieties that Messrs. Carter have imported direct from Japan from time to time. Among the leading varieties very fine are the following:—Mrs. Beale, a very large pure white Japanese, the guard florets in some instances being over an inch in width. James Carter, a charming decorative reflexed variety, the beautiful amber bronze flower being most evenly formed. Mrs. Dunnett, an enormous flower of a rosy blush colour, the points of the petals are quilled and prettily tipped with white. This is a very distinct Japanese. Holborn Beauty, a charming variety in the way of Bend Or, colour bronze. Bronze Queen of England, this variety is now found in all prize groups, it is a grand acquisition. Martha Harding, a rich golden yellow, changing to brown, immense flowers. Prominent amongst older favourites are Baron Beust, Empress of India, Gloria Mundi, Lady Hardinge, Lord Alcester, Mr. Bunn, Mr. George Glenny, Mrs. George Rundle, Princess of Wales, Queen of England, and Venus.

CHRYSANTHEMUM THUNBERG.

I HAVE taken the liberty of sending a small bloom of Thunberg for your inspection. This has been quite the belle of the season with me, and is a beautiful contrast to the two you have lately given us in the Journal. The enclosed bloom is from a terminal bud, and although I have seen the variety exhibited at several shows this season, for refined beauty the bloom I send surpasses any that I have seen.

With your permission I will shortly say a few words on the damping of Chrysanthemum blooms.—FRANK HOPKINS, *Walton-on-Thames*.

[The bloom received is a handsome one of excellent colour, and well merits our correspondent's high opinion of it. We shall also be glad to receive his notes on the damping of blooms, as the subject is one of much importance to growers.]

NARROW VINE BORDERS.

A GREAT quantity of the soil used in the formation of many Vine borders is destitute of roots, and good for nothing but keeping moisture. As I am in favour of the roots of Vines being restricted, perhaps you will allow me to give a description of a viney in its fifth year under what I call root-restriction, and partly on the narrow-border principle. The Vines were planted inside in the usual way in 3 feet of good loamy soil; the outside had the same as the inside, but the roots took to the outside border quicker than to the inside. At the end of the first year's growth, which was splendid, I examined how far the roots had gone into the new soil. They had crossed the new soil and into the old for a considerable distance. Instead of taking care of them I cut off all the ends as they were long and quill-like into the new soil, and did not stop until I found them pretty thickly matted. I gave new soil to the border every year and cut back in the same way as the first year. I have been in places where new soil had to be placed in front of the longest root to make it go faster, but these I consider long underground branches and should be cut back. The Vines are always increasing in strength and fruitfulness. I may say one of the Black Hamburgh bunches weighed over 10 lbs., there were five other bunches on the rod. This is merely stated to show the vigour of the Vine, which I attribute entirely to the above system of root management and not to any particular composition of the soil used, as all it has is a little lime rubbish and wood ashes.—BON ACCORD.

FORCING LILY OF THE VALLEY.

As stated by "M. M." at page 418, these are often very unsatisfactory as seen in many private gardens at Christmas time, but I fear he takes a rather too gloomy view. We generally have our first in by about the second week in January, and I daresay the same means would obtain them by Christmas if we felt so disposed. Many gardeners no doubt purchase the roots too soon from the nurseryman, but when ordering ours I always stipulate that they are to be only sent when they can warrant them well ripened. Another mistake is not supplying sufficient moisture. After receiving ours they are immediately potted; if it is not convenient to do so at once they are covered with damp cocoa fibre refuse in the open air. We place eighteen crowns in a 5-inch pot, and after potting they are plunged in cocoa fibre refuse in the open air, and there remain until brought in for forcing. They are taken into the house and supplied with tepid

water through a rose. The next thing is to plunge the pots to the rims in a propagating case, and the crowns are covered with moss. Success or failure will depend upon their subsequent treatment. Every morning give a good supply of water at about 80° or 90°; do not miss a morning. After the crowns have grown about 1½ inch take off the moss, and in about two days place each pot in pans of water on a shelf close to the glass, and take care to keep the pans filled. The night temperature of our house is about 65°. If the above course of treatment is carried out you will secure a spike of flower and a sheath of foliage to every crown. I grew Lilies for Christmas, when they fetched 15s. per pot in Covent Garden.—A. YOUNG, *Abberley Hall Gardens*.

NOTOSPARTIUM CARMICHAELI.

SEVERAL members of the great family of Leguminosæ present examples of apparently leafless plants, and amongst those cultivated

FIG. 53.—NOTOSPARTIUM CARMICHAELI.

under glass in greenhouses or conservatories such are familiar to many amateur gardeners. *Notospartium Carmichaeli* is an instance of this kind, but not so well known at present, for it has only recently been brought under notice by Messrs. J. Veitch & Sons of Chelsea. It is a New Zealand shrub, of slender habit, with somewhat flattened leafless stems and branches, or with the leaves reduced to scale-like proportions. The neat pea-shaped rosy-purple flowers are borne in dense clusters on the stems as shown in the woodcut (fig. 53). In some districts this no doubt will be found quite hardy, but in any case it should be worth a place in a greenhouse with other plants from the southern hemisphere, and would require the treatment accorded to hardwooded plants.

GRAPES SCALDING.

ONCE more Mr. Bardney has referred to this question, and in two modest columns endeavours to persuade us we are entirely on the wrong scent, also that we have only to follow in his footsteps to insure unbounded success. Now I trust he will not think me dogmatic when I say I still adhere to my argument on this subject. I have read my papers through carefully, and I fail to find where I said it was impossible to scald Black Hamburgs. Such a thing can be accomplished undoubtedly, but I contend not by ordinary culture. My argument may be briefly summed up as follows:—Lady Downe's is more liable to

scald than other Grapes grown under the same conditions. I must remind Mr. Bardney that I had not arrived at any illusionary conclusion respecting the scalding of his Grapes. He is certainly to be congratulated on the successful culture of Lady Downe's. How many gardeners can echo Mr. Bardney's words, "That they have not lost more berries than would make two good bunches in eleven years?" I fear very few indeed. I had almost arrived at the conclusion that scalding was not so prevalent in Lancashire as further south, but I suddenly remembered they find it possible to scald Hamburgs as well as Lady Downe's, a feat I should think is rarely accomplished here. Mr. Bardney appears somewhat surprised to find I should accept his conditional admission for what it was worth—viz., that it would be gross carelessness to scald Black Hamburg as badly as Lady Downe's; conditionally the scalding of both varieties is due to the same cause. Now perhaps he will remember I have never hinted at the cause further than saying it would require an extra dose of the "same cause" to scald the former as badly as the latter. Mr. Bardney tells me his conditional admission is, "That it is gross carelessness to scald Lady Downe's." This is a verdict from which I must leave gardeners to draw their own conclusions. So far as I am concerned, I respectfully differ. Mr. Bardney in company with Mr. Simpson would look for Black Hamburgs scalding in a vinery where little fire heat was used. I can assure him the houses I mentioned as a case passed through the stoning period absolutely without fire heat, and he would have to look in vain for a single scalded berry of that variety, or any other except Lady Downe's.—JAMES B. RIDING.

CHRYSANTHEMUM SHOWS.

WE have to thank numerous correspondents for notes and reports of Chrysanthemum shows in all parts of the country, but the demands upon our space have been so extensive that we have had to rather severely condense the reports of several excellent exhibitions. Some, indeed, we are reluctantly compelled to reserve until our next issue.

TRURO.

THE first Chrysanthemum Show ever held in Truro was opened by the Mayor (Mr. W. J. Johns) in the Concert Hall on Tuesday, November 6th, at noon, and continued the following day. A large schedule of prizes was offered, and the Society was affiliated with the National Chrysanthemum Society. The expectations of the Committee were fully realised, and the Judges (Messrs. James Murton, Richard Gill, and Archibald Mitchell) were highly pleased with the excellent quality of the exhibits. Among those not for competition we might notice some tall plants sent by Mr. J. C. Daubuz-Kilrow. One of the collection was a very large plant of *Sœur Melanie*, containing hundreds of perfectly white blooms. Mr. A. Blenkinsop contributed a well arranged group; also Messrs. Lowry and Laverton. Lady Selborne, trained as a standard, was remarkably good, being heavily laden with flowers. This, together with two other standards, were exhibited by Mr. Laverton. Great praise is due to the Committee for the excellent manner in which the Show was conducted; also to the energetic Hon. Secretary, Mr. A. Blenkinsop.

PLANTS.—The groups of Chrysanthemums arranged for effect were one of the exceptionally beautiful features of the Exhibition, occupying the whole centre of the hall. Class 1 was that for a group of Chrysanthemums arranged in space not exceeding 100 feet, quality and general effect to be the leading features. There were three groups, and the first honours went to Mr. F. Hearnle Cock (gardener, Mr. Bishop) for his exceptionally good collection of dwarf-grown plants. This was the leading feature of the Show, and called forth great commendation. To this collection the Judges awarded the National Chrysanthemum Society's certificate, an honour of which Mr. Bishop may well feel proud. The second prize was given to Messrs. Mill & Tweedie, nurserymen, Truro, for their very large collection, including some extremely choice plants.

The fine collection of Mr. Wm. N. Gill, Truro, occupied nearly the whole length of the hall on the right hand side. He obtained five first prizes in the following classes:—Six specimens large flowered varieties (Japanese excluded), three specimen ditto, single specimen ditto, six specimens Japanese varieties, three specimens Pompon varieties. Mr. A. Laverton was first for single specimen Japanese variety. Mr. Gill's group contained some good plants, his finest being Margot, Peter the Great, Mrs. Dixon, Princess Beatrice, incurred; and a very large plant well-grown of Belle Navarais, white Pompon; Dr. Macary, and Lord Wolseley were exceedingly good specimens.

The only exhibit in the amateur class was a fairly good plant of Soleil Levant, grown by Mr. G. Gradedge, Truro, to which a first prize was awarded. It is to be regretted that the competition among amateurs was so slight. Perhaps the Committee, by offering more liberal prizes another year, may greatly increase the interest in this section.

CUT BLOOMS.—In the class for twenty-four large flowered blooms, and twenty-four Japanese blooms in not less than eighteen distinct varieties of each kind, Mr. Prideaux Brune, Padstow (gardener, Mr. W. Brown), won a well-deserved first, his blooms undoubtedly being the finest in the Show. They were of good size, rare quality, and exquisite colour. The Judges awarded the National Chrysanthemum Society's certificate to Mr. W. Brown for this magnificent display. The varieties shown included:—Large flowered: Empress of India, Gloria Mundi, Alfred Salter, Christine, Novelty, Mrs. Sharpe, Emily Dale, very fine; Lord Wolseley, Queen of England, large; Golden Empress of India, noble flower; Mr. Bunn, Golden Christine, Lady Hardinge, Reine des Blanchés,

Guernsey Nugget, and Lord Alcester, good. Japanese: Baronne de Prailly, Red Gauntlet, Fair Maid of Guernsey, Amy Furze, Soleil Levant, M. Ivon, Ethel, Roseum superbum, M. N. Davis, L'Incomparable, Madame Audiguier, Sultan, Golden Dragon, very good; Comte de Germiny, Triomphe de la Rue des Châlets, splendid flower; L'Adorable, fine; Jeanne Délaux, one of the best; and Mons. Ardène. Mr. W. Lovering, St. Austell, was second. Incurved blooms, twelve distinct varieties. Here again Mr. Brune took first prize, the second being awarded to Mr. W. N. Gill. The lovely display of blooms included the following varieties:—Novelty, Alfred Salter, Inner Temple, Queen of England, Golden Empress of India, very large; Emily Dale, grand show flower; Empress of India, Golden Beverley, White Beverley, Cherub, Lord Wolseley, and Guernsey Nugget.

Twelve Japanese blooms, distinct varieties.—This class produced keen competition; although Mr. Brune scored another first Mr. F. Hearle Cook may well compliment himself on being a good second. Mr. Brune's blooms were Val d'Andorre, grand specimen; M. John Laing, Comte

show flower. A special prize was awarded to Mr. F. Hearle Cook for twenty-four Japanese blooms, distinct varieties.

AMATEUR CLASSES.—All the first prizes were taken by Mr. G. Pappon, Flushing, whose blooms were very fine; Mr. Killstone gained three seconds, the other falling to Miss Hockin, Flushing. The classes were twelve large-flowered, distinct varieties; six ditto; twelve Japanese, distinct, and six ditto.

CLASSES OPEN TO LADIES ONLY.—Miss Michell, Glan Mor, had the best arranged vase of Chrysanthemums and Maidenhair Fern, and was awarded the first prize, Mrs. Lowry being second. Miss Hunkins' collection of autumn leaves, flowers, and berries, grown out of doors, in garden or field, was exceedingly good and much admired. This also received a first prize.

In the same room Messrs. Lucombe, Pince & Co., Exeter, had an exceptionally fine display of Apples and Pears, containing sixty varieties. Among the dishes specially worthy of notice were Tibbett's Pearmain, to which had been awarded the certificate of the National Apple and Pear

FIG. 54.—CYCNOCHES CHLOROCHILON. (See page 462).

de Germiny, Mdle. Lacroix, Soleil Levant, Red Gauntlet, very fine; Jeanne Délaux, Golden Dragon, Fair Maid of Guernsey, large; Triomphe de la Rue des Châlets, Comtesse de Beauregard, and L'Adorable, very good. Mr. F. Hearle Cook's twelve were L'Adorable, Soleil Levant, Golden Dragon, lovely bloom; Comte de Germiny, Meg Merrilies, Balmoreau, Elaine, Japonais, Marguerite Marrouch, Madame J. Laing, very fine; Val d'Andorre, immense bloom, and Mdle. A. Brunel.

Twelve reflexed in not less than six varieties added another first to Mr. Brune's honours. His blooms were the admiration of all, being very finely grown and of good substance. The varieties shown were King of Crimson, Mrs. Forsyth, Christine, good bloom; Cloth of Gold, rich colour; Cullingfordi, and Mdle. Tezier. Six large-flowered Anemone blooms.—The varieties shown by Mr. Brune were Lady Margaret, Mrs. Pethers, good; Gluck, Louis Bonamy, Marginatum, and Princess Charlotte.

Six Japanese Anemone blooms as exhibited by Mr. Brune (first prize) were Madame Cabrol, Ratapoi, and Sœur Dorothe Souille, two of each. Six Pompons, distinct, three flowers of each, to be shown with foliage. This completed Mr. Brune's long list of successes (seven first prizes). The bunches were exceedingly fine, and the blooms very large. The varieties were Aurora Borealis, Sparkler, Madame Elise Dordan, very pretty, compact; Golden Madame Marthe, and Marabout, good

Conference, the Dartmouth Crab, Lord Derby, King of the Pippins, and others. Some of the Pears were of remarkable size, and the whole collection was unique.

DEVIZES.—NOVEMBER 13TH.

THIS Exhibition is always held in connection with a bazaar in aid of the Devizes Benevolent Society, and takes place in the Corn Exchange, the arrangements being, as usual, carried out by Mr. Thomas King, Devizes Castle Gardens. As indicative of high culture it may be stated that the exhibits were of a very meritorious character; the trained plants were equal to, if not superior, to any at the Royal Aquarium. The promoters of the Devizes Show deserve every encouragement, for they offer handsome prizes with a view of drawing exhibitors with the best flowers.

PLANTS.—The best four large-flowered varieties came from Mr. Hale, gardener to C. N. May, Esq., The Elms, Devizes, who had admirably grown and flowered examples fully 4 feet across of Empress of India, George Glenny, Mrs. Dixon, and Lord Alcester. Second Mr. Clack, gardener to C. E. Colston, Esq., Roundway Park, Devizes, his two best specimens being Barbara and Mrs. G. Rundle, but they fell far short of Mr. May's in the matter of quality. Mr. May also had the best three of Mrs. George Rundle, Mr. Dixon, and George Glenny, staging superb

specimens of each, grandly grown and flowered. Mr. Clack was second.

With four specimens of Japanese varieties Mr. May was again first with very finely developed specimens, consisting of *Blanche Fleur*, *Bouquet Fait*, *Soleil Levant*, and *Madame Bertie Randatler*. Mr. Clack was again second, his best specimens being *Madame de Sevin* and *Madame Bertie Randatler*. Pompons in fours were a good feature also, but Mr. May's were far away the best; he had excellent examples of *Mdlle. Martha*, its golden variety *Sœur Melanie* and *Black Douglas*. Second Mr. Clack.

CUT BLOOMS.—These were remarkably fine and well finished. The best twenty-four, not less than eighteen varieties, came from Messrs. W. & G. Drover, nurserymen, Fareham, who had finished examples of *Lord Alcester*, *Alfred Salter*, *Empress of India*, *Queen of England*, *Golden Queen of England*, *Lord Wolseley*, *Jeanne d'Arc*, *Princess of Wales*, *Nil Desperandum*, and Mr. W. Shipman. Second Mr. J. Horsefield, gardener to Lord Heytesbury, Wiltshire, who had some remarkably good blooms also, his leading flowers being *Empress of India*, *Jeanne d'Arc*, *Golden Empress of India*, *Queen of England*, *Bronze Queen*, *Mrs. W. Shipman*, *Mrs. Heale*, *Jardin des Plantes*, and *Alfred Salter*. The best twelve incurved, distinct, were staged by Mr. W. Thomas, gardener to W. Marshall, Esq., Taunton, who had finely finished blooms of *Golden Queen of England*, *Jeanne d'Arc*, *Baron Beust*, *Lord Wolseley*, *Mrs. Heale*, *Lady Hardinge*, *Golden Empress*, *Prince Alfred*, *Jardin des Plantes*, *Queen of England*, *Princess of Wales*, and *Venus*. Second Mr. G. Inglefield, gardener to Sir J. W. Kelk, Bart., Tedworth, Wilts. There was but one exhibitor of twelve varieties shown with 4 inches of stem and foliage, and here Mr. May was again first with excellent blooms of *Empress of India*, *White Venus*, *Lord Wolseley*, *Jeanne d'Arc*, *Nil Desperandum*, Mr. Bunn, *Golden Empress*, and *Princess of Wales*. The Japanese varieties were a great feature, and they were numerous also. Messrs. W. & G. Drover had the best twelve, very fine, consisting of *Boule d'Or*, *Marguerite Marronch*, *Gloriosum*, *Belle Paule*, *Baronne de Prailly*, *Jean Delaux*, *Edwin Molyneux*, *Ralph Brocklebank*, *Criterion*, *Meg Merrilies*, *Madame Baco*, and *Avalanche*, very fine. Second Mr. G. Inglefield, with a very good lot also, his leading blooms being *Madame C. Audiguier*, *Baronne de Prailly*, *Meg Merrilies*, *Mons. Freeman*, *Boule d'Or*, and *Mons. Brunet*. The best stand of twelve reflexed varieties came from Mr. May, *Amy Furze* being particularly fine, also *King of Crimson*, *Chevalier Domage*, *Cullingfordi*, *Mrs. Forsyth*, *Dr. Sharpe*, *Golden Christine*. Second Mr. W. Allen, gardener to Sir C. Russell, Bart., M.P., Swallowfield, Reading. *Anemone* flowered varieties also were a good feature. Here Mr. May was again first with some very good blooms, the varieties being *Lady Margaret*, *Fabian de Mediana*, *Sœur Dorothee Souille*, *Gluck*, and *Mrs. Pethers*. Second Mr. W. Thomas. Baskets of hardy autumn foliage and berries were a charming feature, and were numerous shown, being arranged in exquisite taste; the best came from Mr. Thomas Lewis, Devizes, Miss K. J. Medlicott being second.

Handsome prizes were offered for Chinese Primulas in pots. A very fine lot indeed were shown by Mr. C. N. May, giant plants in 8-inch pots, grandly grown and bloomed. Messrs. Pope & Sons, Great Western Arcade, Birmingham, were second with smaller plants, but good quality of bloom. Mr. Clack had the best six plants. Mr. F. Williams, Devizes, being second. Mr. W. Rose, Devizes, has the best three plants.

There was also a class for twenty-four blooms of Primulas, shown on stands in the same way as Pansies. Messrs. H. Pope & Sons were first, and Mr. Clack second. A first-class certificate of merit was awarded to the new white Japanese *Avalanche*, shown in fine condition by Messrs. W. & G. Drover.

WELLS.—NOVEMBER 13TH AND 14TH.

THIS comparatively young Society has made very rapid progress, and may now safely claim to have attained to the front rank. Classes are provided for plants in variety, cut flowers, and fruit, and in nearly every instance the competition was keen and the exhibits of good quality. Great interest is taken in, and good support given to the Society by the inhabitants of Wells and district, and there was no lack of subscribers and visitors in spite of the unfavourable weather on the opening day. Mr. A. G. Andrews is the Honorary Secretary, and this gentleman was again ably assisted in the management and arranging of the Show by the Honorary Treasurer, Mr. R. Isgar, and a small Committee.

Fairly liberal prizes were offered for groups of plants to consist chiefly of Chrysanthemums, occupying a space not exceeding 8 feet by 4 feet. Of these there were four in competition, all being highly meritorious. Mr. J. B. Payne, gardener to the Lord Bishop of Bath and Wells, was well first, his Chrysanthemums, notably *Belle Paule*, *Golden Dragon*, *Madame Laing*, *Meg Merrilies*, *Fair Maid of Guernsey*, *Balmoreau*, *Val d'Andorre*, *Golden Empress*, and *Alfred Salter*, being remarkably fine. The front of the group consisted chiefly of *Crotons*, *Epiphyllums*, *Eucharises*, and *Ferns*, and altogether a very rich display was made. Mr. T. Wilkinson, gardener to W. C. Tudway, Esq., also had a capital lot of plants, but the quality of the blooms was not so good as those in the first prize group. Equal thirds were awarded to Mr. E. Stokes, gardener to N. McLean, Esq., and Mr. W. McKenzie, gardener to J. H. Brown, Esq., the Chrysanthemums shown by the last named being extra good, but Mr. Stokes had the most imposing group. The best six trained plants of incurved varieties were shown by Mr. Chislett, gardener to Mrs. Rees Mogg, Glastonbury, among these being excellent specimens of *Mrs. Rundle*, *Pink Venus*, *Mrs. Dixon*, and Mr. G. Glenny.

The same exhibitor was also first for Japanese varieties, the best in this instance being *Bouquet Fait*, *Dormillon*, *Nuit d'Hiver*, and *James Salter*. The first prize for six plants, to include three Pompons, were staged by Mr. J. B. Payne, among these being well flowered specimens of *Mdlle. Laeroix*, *Fremy*, and *Bouquet Fait*. Mr. W. Potter, gardener to A. Colson, Esq., was awarded the first prize for a single specimen, winning with a well flowered neatly trained plant of *Sunset*. Mr. Chislett was second with a beautifully flowered plant of *Mrs. G. Glenny*, and Mr. J. Gardener was third. The best four table plants were staged by Mr. J. B. Payne, Mr. T. Wilkinson being second, and F. J. Clark, Esq., Street, a good third. The same positions were occupied by these exhibitors in the class for two fine foliage plants. Mr. Payne was also first with six Primulas, his plants being well flowered and fresh. Mr. E. Stokes was second, and Mr. Gregory third. Mr. Payne was first for double Primulas, and Mr. J. Gardner second.

Cut blooms were both numerous and good. The premier class was for twenty-four distinct varieties, twelve incurved and twelve Japanese. Mr. B. Payne was well first, having grand blooms of *Queen of England*, *Golden Queen of England*, *Alfred Salter*, *Jardin des Plantes*, *Mrs. Halliburton*, *Jeanne d'Arc*, *Prince Alfred*, *Princess Beatrice*, *Golden Empress of India*, *Princess of Wales*, and *Mrs. W. Shipman*, the Japanese being *Golden Dragon*, *Madame C. Audiguier*, *Fair Maid of Guernsey*, *Val d'Andorre*, *Mdlle. Laeroix*, *Belle Paule*, *Gloriosum*, *Mrs. Laing*, *J. Delaux*, *Meg Merrilies*, *Mr. Garnar*, and *Grandiflorum*, all large and fresh. Equal seconds were awarded to Mr. W. A. McKenzie and Mr. T. Wilkinson, both having a fine lot of blooms, marred, however, by three or four bad ones. M. J. M. Pigny and Ralph Brocklebank were well shown by the former, and among Mr. Wilkinson's were fine blooms of *M. Bernard*, *Golden Dragon*, *M. Freeman*, and *Madame Baco*. The third prize was awarded to Mr. J. Bowerman, gardener to C. Hoare, Esq., Hackwood Park, the Japanese varieties in this instance being rather weak. With twelve incurved varieties Mr. J. B. Payne was again well first, among these being extra fine blooms of *Queen of England*, *Alfred Salter*, *Bronze Queen of England*, and *Princess of Wales*. Mr. J. Bowerman was a good second, and Mr. T. Wilkinson third. The prize winners with twelve Japanese varieties were Messrs. Payne, W. M. McKenzie, and Mr. G. Chislett, who received the awards in the order named. A pretty stand of blooms gained Mr. Payne the first prize for *Anemone* flowered varieties, the best of these being *Bacchus*, *Ratapail*, *Sœur Dorothee Souille*, *Mdlle. Cabrol*, *Lady Margaret*, and *Fabian de Mediana*. Mr. Payne was the only exhibitor of Pompon varieties, and his blooms fairly deserved the award of first prize. Amateurs made quite a good display, the most successful amongst these being Mr. J. Gardener, Wells, and Mr. J. Mundy, Street. The competition was good with baskets or vases of hardy foliage and fruit, several ladies displaying great taste, but the vases of Chrysanthemums and bouquets were not so good.

The display of fruit was far superior to that brought together at previous shows, good quality prevailing throughout. In the class for black Grapes Mr. J. H. Stride, gardener to J. Allen, Esq., was placed first for small but perfect bunches of *Gros Colman*, Mr. Payne being second, and Mr. J. Bowerman a very close third, both staging good *Alicante*. For any white Grape Mr. J. Bowerman was well first with well coloured *Muscate of Alexandria*, Mr. Payne being a good second with the same variety. Mr. Bowerman staged a capital dish of *Pitaston Duchess* in the class for a dessert Pear, and was first, Mr. Wilkinson being second with *Doyenné du Comice*. Culinary and dessert Apples were plentiful and good. The best three dishes of the former were staged by Mr. J. B. Payne, these consisting of *Warner's King*, *Peasgood's Nonesuch*, and *Dumelow's Seedling*, all large and of good form and colour. Mr. E. Stokes was second. Mr. J. Bowerman was first for three dessert varieties, these consisting of *Blenheim Pippin*, *King of the Pippins*, and *Queening*, all model fruit. Mr. Payne was a good second. Messrs. Payne and Bowerman were also the prize winners with Tomatoes. Messrs. Brown & Son, Wells, arranged a fine collection of Apples, Pears, Plums, Medlars, Tomatoes, and Gourds, not for competition, and this was highly commended. The same firm had a very pretty collection of Ivies in pots.

WATFORD.

THE third annual Exhibition of this flourishing Society was held in the Agricultural Hall on the 13th and 14th inst. Starting this year with a balance in hand of over £20, the Committee slightly increased the number of the prizes, and they have good cause to be satisfied with the result of their efforts, for the Show was one of the best held this season. Taken collectively the Exhibition exceeded the good all-round quality of last year, although there was a slight falling off in the trained plants. The cut blooms, however, exceeded in size and quality those of any preceding year. Mr. Beckett, gardener to H. H. Gibbs, Esq., Aldenham Park, Elstree, was invincible in all classes in which he competed. No doubt the cut blooms and plants of this exhibitor in previous years have helped to stimulate others in their endeavours to excel.

CUT BLOOMS.—In division 1, for twenty-four incurved blooms, distinct, open to the United Kingdom, Mr. Beckett was a good first with a fine stand of flowers, comprising:—Back row—*Golden Queen of England*, *Jeanne d'Arc*, *Prince Alfred*, *Golden Empress*, *Bronze Queen of England*, *Princess of Wales*, *Lord Wolseley*, *Lord Alcester*. Middle row—Mr. Bunn, *Queen of England*, *Empress of India*, *John Salter*, *Alfred Salter*, *Jardin des Plantes*, *Baron Beust*. Front row—*Angelina*, *Barbara*, *Beauty*, Mr. Brunlees, *White Venus*, *Princess Beatrice*, *Mrs. Heale*, and *Venus*. *Princess of Wales* in this stand was a magnificent

bloom, the best incurved in the Show. Mr. E. Sanderson, Harlesden, Willesden, was second, with very even stands of flowers, well finished, but not so large as the preceding. Third Mr. Cox, gardener to J. Trotter, Esq., Brickenden Grange, Hertford. The succeeding class for a similar number of Japanese was well filled, making a good display. Mr. Beckett was easily first, showing some of the best blooms he has ever staged; they were:—Back row—Album Fimbriatum (very fine), Baronne de Prailly, Carew Underwood, Marguerite Marrouh, Mdle. Laeroix, Madame C. Audiguier, Boule d'Or, and E. Molyneux. Middle row—Soleil Levant, Sceptre Toulousain, Mrs. J. Wright, Sunflower (grand), Jeanne Délaux, Yellow Dragon, Fair Maid of Guernsey, and Sarah Owen. Front row—Madame Baco, Japonais, Val d'Andorre, M. Freeman, Florence Percy, Roi des Japonais, Criterion and La Triomphante. Mr. Cox was second, and Mr. Brown, gardener to R. Henty, Esq., Langley House, Abbots Langley, third.

For twelve incurved Mr. Sanderson secured the first position with fine blooms; Mr. Mundell, gardener to Lord Ebury, Moor Park, Rickmansworth, was a good second with large flowers, but rather uneven; third, Mr. Rumbold, gardener to G. Lake, Esq., Bushey House, Bushey. For the same number of Japanese Mrs. Heasman, gardener to Mrs. Brightwell, was first, Mr. Mundell second, Mr. Rumbold third. With six incurved blooms, one variety, Mr. Beckett was first with large and deep flowers of Princess of Wales; second, Mrs. Sanderson with Princess of Teck; third, Mr. Mundell. Eight competitors staged six Japanese blooms of one variety, and all were good. Mr. Beckett was placed first with very fine Avalanche, Mr. Henty second with Boule d'Or, and third Mr. Cox, showing Ralph Brocklebank. Mr. Mundell in this class spoiled his chance of success by staging a very small Madame C. Audiguier, his other five flowers being excellent examples.

In Division 2, open to members only, the competition was strong in all classes. For twenty-four incurved Mr. Beckett was again first, staging flowers very similar to those enumerated in the open class; Mr. Sanderson second, and Mr. Brown third. For twenty-four Japanese, distinct, Mr. Beckett was also first with excellent stands. With twelve incurved Mr. Mundell was first, and for the same number of Japanese Mr. Kingley, gardener to E. Mawley, Esq., Berkhamstead, won first honours with bright blooms, Mr. Mundell being second.

E. Mawley, Esq., was also first for twelve Japanese in division 3, where not more than two gardeners are employed, and Mr. Layzell, gardener to the Rev. F. K. Gibbs, second. Half-guinea prizes were offered for the best Japanese bloom and the best incurved bloom in the Show, both of which Mr. Beckett was successful in winning. In the former a splendid flower of Album Fimbriatum in his twenty-four stand was selected for the honour, although Sunflower in the same stand was equally good. The best incurved was Princess of Wales, also in this exhibitor's twenty-four stand, a splendid flower of large size and depth, finely finished.

Groups of plants arranged for effect were arranged round the sides of the hall, the competition in the various divisions being very good. For a semicircular group in a space not exceeding 50 feet Mr. Kirby was first with a very good arrangement, his flowers also being large and fresh. Second, Mr. Dinsmore, gardener to T. F. Blackwell, Esq., Harrow Weald. His group contained good plants, but the arrangement in front was too high. In the members' division for a similar sized group Mr. Barnes, gardener to C. R. Humbert, Esq., Watford, was easily first with good plants. Second, Mr. Cox, gardener to O. Thompson, Esq., Bushey Heath. Mr. Layzell was first for a 25-feet group; Mr. Moore second.

TRAINED PLANTS.—These were rather below last year's standard. Mr. Beckett is first for three dwarf trained specimens; Mr. Wilson second; and for three Japanese Mr. Beckett again obtained the first position.

Fruit, plants, and other exhibits were numerous, and the Society was fortunate in having fine weather on both days, the Show being patronised by nearly 4000 visitors, which must be highly gratifying to Mr. C. R. Humbert, the Hon. Secretary, and his hard-working Committee, whose arrangements throughout were excellent.

KENT COUNTY.—NOVEMBER 13TH AND 14TH.

A NEW Society was started this year under the above name, and the first Show was opened on Wednesday, the 13th inst., in the Riuk, Blackheath. The promoters had ample reason to be satisfied with the result of their efforts, as, though there was room in the spacious and convenient hall for more exhibits, the quality of the majority left nothing to be desired. Near the walls were placed the groups of Chrysanthemums and miscellaneous plants, the cut blooms occupying two rows of tables in the centre of the hall, table plants, stands of flowers, and other exhibits being arranged with them.

The cut blooms were of admirable quality, and the competition in some of the leading classes was very keen. This was especially the case in that for twenty-four blooms, eight each of Japanese, incurved, and reflexed, distinct, the three prizes being presented by the President, F.W. Prior, Esq., Gordon House, Blackheath. C. C. Shea, Esq., The Elms, Fooks Cray (gardener, Mr. W. Packman) won first honours, but he was very closely followed by W. C. Pickersgill, Esq., Blendon Hall, Bexley (gardener, Mr. F. Moore), who had an exceedingly fine bloom of Stansstead White amongst his Japanese. The third place was taken by Mrs. Arluthnot, Bridgen's Place, Bexley (gardener, Mr. J. Mitchell). These three collections making an interesting display. Mr. Packman also had the best twenty-four Japanese blooms, and twelve reflexed, all fresh and beautiful blooms. M. Hodgson, Esq., Shirley, Croydon (gardener, Mr. H. Shoesmith) took the first place with eighteen incurved blooms, very clean, fresh, solid blooms, Messrs. Packman and Leadbetter following. Cut blooms in several other classes were well shown, and some excellent

non-competing stands were staged by T. Wickham Jones, Esq., South Norwood. Groups of Chrysanthemums furnished a considerable attraction, F. P. Preston, Esq., South Bank, Blackheath, winning first honours, while the extensive and well arranged non-competing groups from Messrs. Davis & Jones, Camberwell, and Messrs. J. Laing & Sons, Forest Hill, secured the Society's special award of merit. The Hon. Secretary, Mr. H. A. Needs, with the Committee, of which Messrs. Norman Davis and J. H. Laing are prominent members, may be congratulated on having made a good beginning.

BRIGHTON.—NOVEMBER 13TH AND 14TH.

THE sixth annual Exhibition of the Brighton and Hove Chrysanthemum Society was held in the Pavilion. The arrangements were excellently managed, under the superintendence of Mr. Mark Longhurst, the courteous Secretary, assisted by an efficient Committee.

Cut blooms were staged to the number of over 1100, and were of good average quality, the Japanese being heavy and of good quality. Incurved varieties showed a roughness and want of finish which is somewhat prevalent this season. The great class was for forty-eight large flowered varieties, half to be incurved and the remainder Japanese, all to be distinct. This is generally a difficult class to fill, yet it on this occasion brought six competitors. The first prize was awarded to Messrs. W. and G. Drover, nurserymen, Fareham, Hants, the Japanese being the best in quality, the incurved being rather small in the front row; the back and middle rows contained some handsome blooms. The names were:—Incurved:—Back row—Empress of India, John Salter, Golden Empress, Queen of England, Golden Queen of England, Lord Alcester, Princess of Wales, Guernsey Nugget. Middle row—Mrs. W. Shipman, Lady Hardinge, Lord Wolseley, Alfred Salter, Mr. Heale, Prince Alfred, Empress Eugénie, Nil Desperandum. Front row—Lady Slade, Venus, Cherub, Jeanne d'Arc, Nonpareil, Princess Teck, Jardin des Plantes, and Prince of Wales. Japanese—Back row—Madame Baco, Margaret Marrouh, Boule d'Or, Belle Paule, Edwin Molyneux, Gloriosum, Baronne de Prailly, Fimbriatum. Middle row—Album Fimbriatum, Madame C. Audiguier, Meg Merrilies, Ralph Brocklebank, Avalanche, Carew Underwood, M. J. M. Pigny. Front row—M. Freeman, Mrs. J. Wright, M. W. Holmes, Balmoreau, Criterion, Jeanne Délaux, Maggie Mitchell, and Val d'Andorre. Second, Mr. J. Hopkins, gardener to R. Thornton, Esq., J.P., High Cross, Framfield. Third, Messrs. W. Ray & Co., Mount Pleasant Nursery, Green Street, Siltingbourne.

For twenty-four incurved, distinct, there were five competitors. A singular occurrence took place in this class. The stands which should have been placed second and third were disqualified, owing to their containing duplicate blooms, in one instance of Queen of England and the other of Empress of India. Mr. J. Hopkins was placed first for medium sized blooms, fairly well finished. Back row—Lord Alcester, Bronze Queen of England, Jeanne d'Arc, John Salter, Queen of England, Lord Wolseley, Empress of India, Alfred Salter. Middle row—Princess of Wales, Golden Queen of England, Venus, Cherub, Mrs. W. Shipman, Golden Empress, Bronze Jardin des Plantes, Princess Beatrice. Front row—Baron Beust, Lady Hardinge, Mabel Ward, Prince of Wales, Mr. Bunn, Sir Stafford Carey, Princess Teck, Nil Desperandum. Mr. M. Russell, gardener to Dr. C. F. Lewis, Henfield, Sussex, small neat blooms. Six competed for twenty-four Japanese distinct, making in all a good show. Messrs. W. & G. Drover again occupied the leading position with heavy, even, and fresh blooms, but only by a very few points. The varieties were:—Back row—Mdme. Baco, Mdle. Laeroix, Boule d'Or, Edwin Molyneux, Avalanche, Ralph Brocklebank, Meg Merrilies, Maggie Mitchell. Middle row—Album Fimbriatum, Belle Paule, M. J. M. Pigny, Mdme. C. Audiguier, Gloriosum, Fimbriatum, Baronne de Prailly, M. H. Elliott. Front row—Gorgeous, Jeanne Délaux, Margaret Marrouh, Criterion, Carew Underwood, Japonaise, L'Adorable, Mrs. J. Wright. Mr. T. Glen, gardener to Mrs. Montefiore, Worth Park, Crawley, was a close second. Third, Mr. G. Dunnean, gardener to S. T. Lucas, Esq., Warnham Court, Horsham. Of twelve incurved, nine boxes were staged, Mr. C. Fowler, gardener to Mrs. Hall, Barrow Hill, Henfield, medium size blooms, even and finely finished. Mr. W. Jupp, gardener to G. Boulton, Esq., Torfield, Eastbourne, was second with larger blooms, but not of such good form, and Mr. C. Sayers, gardener to Mrs. Cook, The Hall, Uckfield, third.

Mr. C. Fowler staged the best twelve Japanese amongst eight competitors—large, even, fresh blooms of Madame C. Audiguier, M. Délaux, M. J. M. Pigny, Carew Underwood, Elaine, Belle Paule, Marguerite Marrouh, Madame Laing, Thunberg, Jeanne Délaux, Soleil Levant, and Criterion. Mr. J. Snow, South Park, Wadhurst, was second with larger blooms not quite so fresh. Mr. F. Godby, gardener to Dr. Withersmore, The Oaks, Burgess Hill, was third. Nine staged six incurved, distinct. Mr. C. Fowler was again first with medium-sized even fresh blooms; second Mr. Jupp with larger, but rougher specimens; Mr. Snow third. For six Japanese, distinct, Mr. Snow was first; second Mr. F. Godby, third Mr. C. Fowler, all staging well. Messrs. Drover had the best six Anemones, full solid blooms, with the centres well up—Jean Marty, Minnie Chate, Lady Margaret, Miss Annie Lowe, Mrs. Pethers, and Margouline. Mr. Snow was second with large blooms, but the centres not so well up. Messrs. Drover again occupied leading honours for six reflexed amongst six exhibitors with substantial blooms of Amy Furze, Mdle. Madeleine Tezier, Cullingfordi, Golden and Pink Christine, and Cloth of Gold; Mr. F. Godby second. Mr. Snow staged Queen of England, large, but rather flat, for six of any incurved variety; Mr. M. Russell second with fresh blooms of Golden Empress, small and bad centres; Mr. C. Fowler with Mrs. Heale took the third place. Eight stands of six blooms of any one variety of Japanese were staged,

Mr. T. Glen took first honours with excellent specimens of *Mdlle. Lacroix*; Mr. Snow second with the same variety; Mr. G. Coleman, nurseryman, West End, Henfield, was third with *Madame C. Audiguier*, small but fresh. Mr. G. Russell staged the best twelve Pompons, three in a bunch with foliage, a fine lot, the best *Rubrum Perfection*, Marabout, Comte de Morney, *Mdlle. Elise Dordan*, and *Briolis*, *Antonius* and *Marguerite de Coi* as *Anemone Pompons*; Mr. G. Dunnean second with a good lot; Mr. G. Coleman third. For the best two blooms, one Japanese and one incurved, shown in glasses, Mr. J. Hopkins was first with *Empress of India* and *Fair Maid of Guernsey*, good. The best bouquet of *Chrysanthemums* with any foliage was staged by Mr. Rupert Miller, Southdown Nursery, Shoreham. Mr. M. Kent, 4, Campbell Road, Brighton, had the best stand for table decoration, a light arrangement.

Specimen plants were not of a high order of merit, being small, not too freely flowered, the best four plants coming from Mr. Meachin, gardener to Mrs. Armstrong, Woodslea, Withdean. Standards are made a feature at Brighton. The heads range from 2 to 3 feet across, and about that high are generally freely flowered, this time were rather stiffly trained, the best four standards coming from Mr. J. Hill, gardener to M. Wallis, Esq., Springfield, Withdean; second, Mr. A. Scutt, gardener to T. Jenkins, Esq., Franklands, Burgess Hill. Mr. Hill staged the best single specimen standard, one of *Roseum Superbum*, freely flowered. Mr. Meachin staged the best four pyramids about 3 feet high. A first prize of £5 was offered for a group of *Chrysanthemums* 100 square feet. Mr. Bunney, gardener to J. Campion, Esq., Danny Park, Hurst, a sloping bank of plants freely flowered, grown in bush fashion was used, which present a mass of small flowers, but lacked the quality of the groups as seen at the metropolitan exhibitions. Mr. J. Turner, gardener to Major Way, Wick Hall, Hove, was second with a similar group, not quite so good in quality.

Fruit made a good show, capital Apples and Pears being staged, the best four dishes of the former dessert varieties and the same number of culinary sorts, while much the best four dishes of dessert Pears was also staged by Mr. C. J. Goldsmith, gardener to Mrs. C. A. Hoare, Kelsey Manor, Beckenham, was easily first in all classes with fine fruits. Mrs. Goldsmith was also first for three bunches of white Grapes with *Muscata* of *Alexandria* in good condition. For the same number of black bunches there were nine competitors, Mr. J. Buckstone, gardener to J. Butler, Esq., The Laurels, Withdean, leading with *Alicante*, good bunches, medium sized berries, and well finished. Vegetables and miscellaneous exhibits were numerous and of excellent quality.

WINCHESTER.—NOVEMBER 13TH AND 14TH.

THE Guildhall was the site chosen as usual for the annual Exhibition of *Chrysanthemums*, fruit, &c. Plants were staged in capital condition by Mr. W. Joy, Mr. Wills, Mr. J. Kaines, and Mr. F. Smith. For a group of *Chrysanthemums* Mr. G. Wareham was an easy first; Mr. G. Sergeant following.

Cut blooms constituted the leading part of the Exhibition, the competition in most classes being keen, and the quality good throughout. The leading class was that for forty-eight, twenty-four to be incurved or reflexed in not less than two blooms of any variety, and the same number of Japanese. The first prize was a challenge cup presented by the Mayoress and ladies of Winchester, the conditions being that it should be held by the winner for one year only, remaining the property of the Society. Three competitors entered the list. The verdict of the Judges, after much deliberation, was given in favour of Mr. Neville, gardener to F. W. Flight, Esq., Twyford, Winchester. The varieties in Mr. Neville's stand were as follows, the incurved being of medium size in the back and middle rows, while the front row was small, but beautifully finished:—*Golden Queen of England* (2), *Princess of Wales*, *Golden Empress*, *Queen of England*, *Bronze Queen of England* (2), *Lord Alcester*, *Empress of India*, *Jeanne d'Arc*, *Lord Wolseley*, *Alfred Salter*, *Nil Desperandum*, *Golden Empress*, *Prince Alfred*, *Venus*, *Barbara*, *Mrs. Heale* (2), *John Salter*, *Mrs. W. Shipman*, *Hero of Stoke Newington*, and *Mr. Brunlees*. Japanese:—*Edwin Molyneux* (2), *Val d'Andorre*, *L'Or du Japon* (2), *Carew Underwood*, *Gloriosum*, *Madame Dubrueil*, *Madame C. Audiguier* (2), *Mrs. J. Wright*, *Madame Laing*, *Avalanche* (2), *M. Brunet*, *Buffalo Bill*, *Duke of Berwick*, *Soleil Levant*, *Maiden's Blush*, *Mr. Garnar*, *Stanstead White*, *Marguerite Marrouch*, *Thunberg*, and *Mr. W. H. Benbridge*. The back row in Mr. Molyneux's stand of incurved blooms were especially heavy and well finished; the Japanese were throughout large, well coloured, and arranged. Messrs. W. & G. Drovers, The Nurseries, Fareham, were third.

For twenty-four blooms, not less than eighteen varieties, Mr. Trinder, gardener to Sir H. St. Mildmay, Dogmersfield Park, Winchester, was easily first, the Japanese large and fresh, the incurved were of medium size and neatly finished; Mr. C. Warden, gardener to Sir F. Bathurst, Clarendon Park, Salisbury, second; Mr. Willis third, both staging well. For twelve incurved, distinct, Mr. Neville was first with medium-sized, well-finished blooms, Mr. Molyneux a very close second, Mr. Trinder third. For six incurved Mr. F. Annalls, gardener to Chaloner Shenton, Esq., The Glen, Golden Common, Winchester, was a good first; Mr. A. Prouting, gardener to Miss Butler, Winchester, second. For twelve Japanese, distinct, Mr. Molyneux led the way, with even brightly coloured blooms; Mr. C. Brooks, gardener to H. A. Simmonds, Esq., Red Rice, Andover, and second. Third, Mr. Neville, who was also placed first for twelve reflexed in not less than eight varieties with even, fresh specimens. Mr. C. Brooks was again second. Mr. Neville was also first for twelve *Anemones*, with

good, clean specimens, Messrs. Drovers second. The best blooms of *Pompons* were staged by Mr. Neville, but as he did not comply with the conditions of the schedule—distinct varieties—he duplicating two varieties which the Judges failed to see, he should have been disqualified. Mr. T. Annalls was a good second, judging correctly the stipulated number. Fruit was of good quality.

WESTON-SUPER-MARE.—NOVEMBER 14TH.

FORTUNATELY for this Society fine weather prevailed throughout the day, and it is to be hoped a capital attendance of visitors would more than compensate for the loss resulting last year owing to the unfavourable weather. The Show was held in the Victoria Hall, but this was scarcely large enough owing to a great increase in the number of entries. It was very well arranged, and Messrs. W. H. Vanes and S. Lewis, the Honorary Secretaries, and a committee of gentlemen interested in horticulture and practical gardeners, are to be congratulated upon the result of their labours.

Among the numerous trained plants of *Chrysanthemums* shown there were many that were most praiseworthy, and a considerable number that were much disfigured by a free use of large unpainted deal stakes. The best six flatly trained specimens of large-flowering varieties were staged by Mr. W. Brooks, Weston-super-Mare, these consisting of Mrs. Dixon, Prince Alfred, Mr. Glenny, Prince of Wales, Mrs. G. Rundle, and Gloria Mundi, all well grown and fresh. Mr. C. Holland, gardener to W. Ash, Esq., Weston-super-Mare, was a close second, his plants losing in point of size only. Mr. W. Browne, gardener to the Rev. W. W. Aldridge, Weston-super-Mare, was first, and Mr. W. Daffurn, gardener to F. D. Cox, Esq., Weston-super-Mare, second for four plants of large-flowered varieties. The first prize for six Japanese varieties was awarded to Mr. C. Holland, who had beautifully flowered well trained specimens of *Souree d'Or*, *Elaine*, *Margot*, *Bouquet Fait*, *James Salter*, and *Madame Bertie Rendatler*, the latter plant also being singled out as being the best specimen of a Japanese variety in the Show. In this class Mr. W. Brooks was second, and not much fault could be found with his exhibits. Mr. W. Browne was first for four Japanese varieties, and Mr. W. Daffurn second. Several creditably flowered pyramids were shown in the different classes provided for them, the most noteworthy among these being staged by Mr. C. Holland. The last named also had much the best standard trained plants of any varieties, the specimens of Mrs. Forsyth, *Jardin des Plantes* and *Christine* being noteworthy. A remarkably well-grown dwarf-trained specimen of Mrs. G. Rundle gained Mr. Holland a first prize and a special award as being the best specimen of incurved variety in the Show. Mr. W. Brooks was a creditable second. There was a good display of dwarf-trained *Pompon* varieties, the best six plants consisting of *Astarte*, *Mdlle. Marthe*, *Cedo Nulii*, *Marie Stuart*, *Alala*, and *Bob*, all beautifully flowered, being staged by Mr. C. Holland, the second prize going to Mr. Brooks, who also had several good plants. Groups of *Chrysanthemums* were not so good as usual, that which gained Mr. Brooks the first place evidently being arranged in a very hurried manner. The quality of the flowers was good, hence its being placed in front of that arranged by Mr. Lewis, gardener to J. E. Cole, Esq. Mr. W. Brooks was well first with a good group of miscellaneous plants, and Mr. C. Holland second. A grand bank of Tree Ferns, *Adiantums*, *Aspleniums*, *Palms*, *Crotons*, and other plants was formed by the exhibits in the classes for six Ferns and six fine-foliaged plants, and this was quite a feature in the Exhibition. Mr. W. Daffurn was first for six richly coloured *Primulas*, and Mr. W. Brooks a good second.

Cut flowers were shown in greater numbers than usual, and made quite an imposing display. The best twenty-four large flowered varieties was staged by Mr. E. Miller, Old Sneyd Park, Bristol, the most noteworthy among these Alfred Salter, Princess Teck, Bronze Queen of England, Lord Wolseley, Queen of England, Cherub, Mr. Bunn, John Salter, Jeanne d'Arc, Mr. N. Davis, Prince Alfred, Lord Alcester, and Barbara. Mr. W. Brooks was second, his best being Princess of Wales, White Globe, Cherub, Venus, Alfred Salter, and Barbara. Mr. W. Lewis was third. Mr. C. Holland was first for twelve varieties, among these being good blooms of Jeanne d'Arc (the premier bloom of large flowered variety in the Show), Queen of England, Empress of India, Venus, and Isabella Bott. Mr. W. Daffurn was a good second, his best being Lord Wolseley, Alfred Salter, and Golden Empress of India. Mr. W. Coates, Westbury-on-Trym, was first for six varieties. The competition, as in the other classes, was fairly good with twenty-four Japanese varieties, and with these Mr. E. Miller was first. His best were Thunberg, E. Molyneux, Soleil Levant, Baronne de Prailly, L'Adorable, Fimbriatum, F. Marrouch, Mons. Brunet, J. Delaux, Criterion, and Mr. Orchard. Mr. W. Brooks was second. In the class for twelve Japanese varieties Mr. Daffurn was first, his best being Val d'Andorre, Madame C. Audiguier, Meg Merrilies, M. Brunet, Boule d'Or, Madame Laing, Baronne de Prailly, and Fair Maid of Guernsey. Mr. C. Holland was second. Mr. W. Coates was first for six varieties, and Mr. E. Wheeler, gardener to Mrs. Charrington, second. Only two stands of *Anemone*-flowered varieties were staged, and with these Mr. E. Miller was first, and Mr. W. Brooks second. Mr. W. C. Winstone, Clifton, was first for a hand bouquet, this being moderately large, and composed of Orchids in variety, Lilies of the Valley, Stephanotis, *Paneratiums*, and other choice flowers most tastefully arranged. Mr. W. Brooks, who was second, also had a very good bouquet. The last named was well first for an epergure, in which a choice assortment of flowers were prettily arranged. Mr. Winstone was a good second. Mr. Brooks was first, Mr. Holland second, and Mr. Winstone third with baskets of autumn foliage, grasses, and fruit.

The fruit classes were better filled than on any previous occasion, and the quality generally was good. In the class for any white Grape Mr. W. Coates was well first with two large and remarkably well finished bunches of Muscat of Alexandria, and Mr. Miller second with the same variety. Mr. W. Daffurn took the lead with black Grapes, having well finished Alicante; Mr. W. Hughes being second with fairly good Mrs. Pince. The first prize for four dishes of Pears was awarded to Mr. W. Daffurn, who had sound well coloured fruit of Beurré Clairgeau, Marie Louise, Beurré Diel, and Doyenné du Comice. Mr. W. Lewis was second. Mr. Daffurn was also first for a single dish, staging good Doyenné du Comice; the second prize going to Mr. E. Wheeler, who had a clean dish of Duchesse d'Angoulême. Each exhibitor in the class for four dishes of culinary Apples infringed the rules, and no award was made. With one dish, Mr. E. Brooks, Cheddar, was first for fine well coloured fruit of New Hawthornden, and Mr. W. Browne second with fine Warner's King. Mr. R. Carey was first for four dessert varieties, these consisting of Cox's Orange Pippin, Rosemary Pippin, Adam's Pearmain, and Worcester Pearmain, all well selected; Mr. W. Lewis was second. The last named was first for a single dish, and Colonel Mordaunt second.

BIRKENHEAD AND WIRRAL SHOW.—NOV. 14TH AND 15TH.

THIS Society held their second Exhibition in the Town Hall on the above dates, and though not a large one, it was neat, and the exhibits were considerably in advance of what were staged last year.

The schedule provided twelve classes for cut blooms, half of them being open to all, and the remaining half for local competitors. In the open classes for twenty-four incurved, not less than eighteen varieties, Mr. J. Gould, gardener to R. N. Dale, Esq., Bromborough Hall, was well to the front with large fresh flowers. The varieties were:—Back row—Queen of England, Golden Empress, Empress of India, Lord Wolseley, Empress of India, Lord Alcester, Queen of England, and Golden Empress. Middle row—Emily Dale, Alfred Salter, John Salter, Jeanne d'Arc, Lord Alcester, Mrs. Heale, Lord Wolseley, and Jeanne d'Arc. Front row—Princess of Wales (good), Refulgence, White Beverley, Pink Venus, Mr. Bunn, Princess Beatrice, White Venus, and Prince Alfred. Mr. G. Burden, gardener to G. Cockburn, Esq., Oxtou, was second, the two collections only were staged. In the corresponding (local) class for eighteen distinct varieties, the last-named exhibitor was well to the front. Mr. J. Gould was a good second, and Mr. E. Broadey, gardener to H. Jones, Esq., Hooton, third. For twelve blooms (open) Mr. G. Lyon, gardener to J. H. Kenion, Esq., Rock Ferry, took the premier award amongst three competitors, with good blooms of the following:—Back row—Empress of India, Queen of England, Lord Alcester, and Jeanne d'Arc. Middle row—Alfred Salter, Mr. Bunn, Lord Wolseley, and Golden Empress. Front row—White Venus, Refulgens, Jardin des Plantes, and Prince Alfred. Mr. E. Broadey was placed second; Mr. R. C. Townsend, gardener to Sir W. B. Forwood, Blundellsands, third. In the local class for twelve blooms Mr. C. Smith, gardener to D. Wilson, Esq., Devonshire Place, was well first.

In the open class for twenty-four Japanese, not less than eighteen varieties Mr. J. Gould was first with fresh large well coloured flowers of the following:—Back row—Boule d'Or, E. Molyneux, Belle Paule, Meg Merrilies, M. Tarin, R. Brocklebank, E. Molyneux, and Boule d'Or. Middle row—Marguerite Marrouch, Mdle. Lacroix, Criterion, J. Delaux, Golden Dragon, Val d'Andorre, Elaine, and Belle Paule. Front row—R. Brocklebank, Madame J. Laing, Avalanche, Thunberg, Mdle. Lacroix, Comte de Germiny, J. Delaux and Gloriosum. Mr. G. Burden was second, neat but small blooms. Mr. T. Winkworth, gardener to R. Brocklebank, Esq., Childwall Hall, third with even smaller flowers. In the corresponding local class for eighteen distinct varieties Mr. G. Burden was successful, and staged very fine flowers. Messrs. J. Gould and Broadey were the prizewinners in the order named. For twelve Mr. G. Burden again took the lead, having a remarkably fine flower of Mdle. Paule Dutour. Mr. C. Waring, gardener to Mrs. J. Aikin, Princess Park, was a good second, and Mr. E. Broadey third, with flowers uneven in size.

Fruit, plants, and miscellaneous exhibits were numerous and of a very interesting character.

BEDFORD.—NOVEMBER 14TH AND 15TH.

THE second annual Exhibition of this Society was held on the 14th and 15th inst., in the Corn Exchange, Bedford. The Show was far in advance of last year. The groups of Chrysanthemums and other plants were arranged on the sides of the hall in a semicircle, with tables down the centre for cut blooms, fruits and vegetables, and ample room between for visitors. In the open class for a group of Chrysanthemums not exceeding 50 feet square, Mr. J. C. Sheppard, nurseryman, Bedford, was first with a neat arrangement; C. Franklin, Esq., Bedford, second (gardener, Mr. G. Vine); third, F. Howard, Esq., (gardener, Mr. Robinson). Division B, open to amateurs and gardeners in the county of Bedford.—These groups were similar to the open classes but smaller, Mr. R. Waller, gardener to J. P. Howard, Esq., Clapham Park, was first; second, Mr. R. Day, gardener to J. Hawkins, Esq., Mayor of Bedford. An edging of foliage plants is allowed round the groups, which is a step in the right direction, as it is always difficult to grow Chrysanthemums dwarf enough. The edgings employed were chiefly Maidenhair Ferns, *Isolepis gracilis*, and other light foliage plants. The great feature of the Show were the cut blooms in the open classes. Mr. R. Adams, gardener to G. B. Hudson, Esq., Frogmore Hall, Herts, was easily first

with twenty-four incurved; Mr. J. Kipling, gardener to Lord Lytton, Knebworth, Herts, was a good second. For twenty-four Japanese the same exhibitors were awarded the first and second prizes in the order named above.

Grapes were not numerous, but for two bunches of Alicante Mr. G. R. Allis, gardener to Major Shuttleworth, Old Warden Park, was first with grand bunches, well coloured, and carrying a good bloom; Mr. R. Day, gardener to J. Hawkins, Esq., was second with rather loose bunches but well coloured berries. In the class for white Grapes Mr. G. R. Allis was first for two bunches of well ripened Golden Queen. Apples and Pears were a good show. Four dishes culinary Apples, first, Mr. Allis; second, Mr. R. Day; third, Mr. J. Herman. Four dishes dessert Apples, first, Mr. G. R. Allis; second, Mr. R. Day; third, Mr. J. Herman. Much more might be said of the several other exhibits if space would allow. Through the efforts of the energetic Hon. Secretary, Mr. J. Sanders Clarke, and a hard-working Committee the Show was well arranged.

BOURNEMOUTH.—NOVEMBER 14TH AND 15TH.

MILD in winter and cool in summer, with a grand sea view and a rising background of Pine-clad slopes, with Arbutus trees laden with flowers in November, and some of them with Strawberry-like fruits, with handsome villas widely scattered, broad well-kept tree canopied roads, and sundry other charms, including picturesque gardens, some two miles long, there is no wonder this healthy seaside resort should be so much patronised by visitors from this and other countries. It is in every way a delightful town—a town without streets it may be called—a town of grand hotels and pleasant villas containing apartments for visitors. These are constantly increasing in number, and will increase now that the London and South-Western Railway Company have opened a new and direct route, and provide trains which run from the metropolis in a little over 2½ hours. It would be strange if such a fashionable town as this should not have an Exhibition of the fashionable flower—the Chrysanthemum—hence a Society is established, of which H.R.H. the Princess Christian is the chief patroness. The Show was held in the new and capacious covered tennis court of the Mont Dore Hotel, a palatial building, most pleasantly situated a little distance from the sea.

As only half an hour was at disposal for "taking notes," it can only be said that the groups and cut blooms were the most worthy of inspection, as trained specimen plants were scarcely represented. There were, however, several of what may be termed conservatory plants that occupied the centre of the building, and in the mass were effective. Very good fruit and vegetables were also exhibited, and several bouquets.

In the open class of twenty-four incurved blooms in not less than eighteen varieties, the first prize was won by Mr. W. Osborne, gardener to Rev. H. Hopkins, with Empress of India (3, and premier bloom), Princess of Wales (3), Golden Empress (2), Alfred Salter (2), Jardin des Plantes (2), Jeanne d'Arc, Empress Eugénie, Hero of Stoke Newington, Lord Alcester, Baron Beust, Queen of England, Lord Wolseley, White Globe, White Venus, Nil Desperandum, sport from Guernsey Nugget, and Countess of Dudley, a regular stand of fresh medium-sized blooms. Mr. T. K. Ingram was placed second with neat good blooms, equal to the others in culture, but several of them a week too old. Mr. W. Gallop, gardener to H. N. Middleton, Esq., was a good third, but the date was too late, as several of them had lost their freshness. In the class for twelve incurved (local), Mr. W. Ward, gardener to Mrs. Colville, secured the foremost place with Queen of England, Beauty, Princess of Wales, Alfred Salter, Prince Alfred, Mrs. N. Davis, Jardin des Plantes, Jeanne d'Arc, Lord Wolseley, and Princess Teck, even and good; not distantly followed, however, by Mr. T. Gould, gardener to Mrs. Dawson Danver, and Mr. T. K. Ingram.

Japanese blooms were well represented; they were fresher on the whole than the incurved, and the prizes were well contested. Mr. W. Gallop secured the chief position in the open class of twenty-four blooms with Maider's Blush (2), Comte de Germiny (2), Jeanne, Delaux (2), Belle Paule (2), M. Ardene (2), Lady Lawrence (2), Thunberg, Comtesse de Beauregard, Mdle. Lacroix, Madame C. Audiguier, Soleil Levant, Fair Maid of Guernsey, Baronne de Prailly Grandiflorum, Madame Bouchardat, Val d'Andorre, and Madame Bertie Rendatler—a good stand, in which Jeanne Delaux was the premier of the Show. Messrs. T. K. Ingram and W. Osborne were the other prizewinners in the class, both presenting creditable stands. Messrs. G. Garner (gardener to Mrs. Braddly), T. K. Ingram, and T. Gould were the respective prizewinners with twelve blooms, all the stands good. The first contained excellent examples of Madame C. Audiguier, Golden Dragon, Belle Paule, Thunberg, La Triomphante, Mdle. Lacroix, Val d'Andorre, Elaine, Comte de Germiny, Maiden's Blush, Peter the Great, and Criterion. Mr. F. J. Ellis was first with six reflexed, staging in very good condition Cloth of Gold, Amy Furze, Cullingfordi, Pink Christine, Mdle. Tezier and Phidias; Messrs. Ingram and Ward following. Mr. Ellis was also successful with six Anemones, the varieties being Mrs. Pethers, Lady Margaret, Cincinnati, Souvenir de Lardenne, and Gluck.

Passing some of the other local classes, it may be said briefly that by far the best large group of plants, both in quality and effect, was arranged by Messrs. G. Watts & Sons; Mr. F. J. Ellis second, with tall plants but good blooms, and Mr. Ingram third with a too stiff and formal arrangement, a fourth prize being granted to Mr. Earp. In the smaller (amateur) class, the prizes were awarded to Messrs. Sola, Stead-

dall, and Symons. In the single-handed gardeners' class, Mr. J. Biles, gardener to F. Atken, Esq., distanced all competitors with a very creditable arrangement. The best gardeners' bouquet was very good, and was exhibited by Mr. Garner, and much the best ladies' bouquet by Miss Watson. Mr. Richards, Someley Gardens, staged the best Grapes, and Mr. Williams, Canford, the best Apples and Pears. The Exhibition was enriched by special groups of plants contributed by the following local nurserymen and florists—Mr. J. Swaffield, Mr. Ingram, Mr. Haskins, Mr. Watts, and Messrs. W. Stewart & Sons; also by Messrs. Cooling and Sons of Bath.

It may be added, as a pleasant surprise, that in seeking a night's accommodation we were fortunate in finding the proprietor of the handsome villa, 10, Westover Road, Mr. J. G. Harding, a near relative of Mr. A. Harding of Orton Hall Gardens, Peterborough, and as our host had been for forty years butler to the late Bishop of Llandaff, he knows how to make his guests comfortable. This visit to Bournemouth was too short, yet enjoyable, for the town and its surroundings are unique, and it is no wonder that those who have once seen it have a wish to go again. It is hoped the Chrysanthemum Show proved a financial success.

WORCESTER.—NOVEMBER 15TH.

AFTER a lapse of five years this Society held an autumn Show, which was well patronised by the public. There was good competition in the Chrysanthemum classes, also for groups of plants arranged for effect to occupy 100 square feet. Mr. Gwynne, gardener to T. R. Hill, Esq., taking the lead in the latter class with a neat group of brightly coloured Dracenas, Crotons, &c. Mr. J. H. White was second. His group was neatly arranged, although it contained no plants of special merit. Mr. J. W. Sedgley, gardener to Mrs. Holland, was third. In the class for twelve Chrysanthemums, distinct varieties, in pots not to exceed 12 inches in diameter, Mr. Sedgley, gardener to Mrs. Holland, was an easy first; his plants were neatly trained about 4 feet over, and covered with fresh blooms and healthy foliage. Mr. Maylett was second. In the corresponding class for six plants Mr. Sedgley was again first. Mr. Gwynne was second with good blooms but smaller plants. There were classes for single specimens, Mr. Sedgley being first for Japanese with a fine plant of Elaine, Mr. Gwynne second with Hiver Fleuri, and Mr. Maylett third. For a single specimen incurved Mr. Gwynne was first, Mr. Sedgley second, and Mr. Maylett third. For a single Pompon Mr. Sedgley was first and Mr. Maylett second.

There was an excellent display of cut blooms for twenty-four distinct varieties. Mr. Froud, gardener to the Rev. Coventry, was first with good blooms, the best of which were Jeanne d'Arc, Lord Alcester, Queen of England, Lord Wolseley, Prince Alfred, Edwin Molyneux, Madame C. Audiguer, and Jeanne Délaux. Mr. Gwynne was a close second, and Mr. Maylett third. For twelve incurved the tables were turned, Mr. Gwynne being first with fine blooms, Mr. Froud being second, Mr. Maylett third. For twelve Japanese Mr. Gwynne was again first, Mr. Maylett second, and Mr. Froud third. Mr. Sedgley was first for six Primulas single, Mr. Jones second, Mr. Maylett third. With six double Primulas Mr. Maylett was first. Mr. Childs, gardener to Earl Coventry, was first for a collection of six dishes of fruit, which contained excellent Gros Colman Grapes, and Muscat of Alexandria, good Melon, Pears, Apples, and Medlars. Mr. R. Robbins, Rhydd Court, was first for six dishes of Pears, and Mr. Childs second.

WIMBLEDON.—NOVEMBER 15TH.

A BRIGHT and pleasing Show was held in the Drill Hall, Wimbledon, on Thursday last, cut blooms, groups, fruit, and miscellaneous exhibits being numerous and satisfactory in quality. Mr. C. Gibson, Morden Park Gardens, scored a series of successes, taking premier honours in several classes with fresh substantial blooms of incurved, Japanese, reflexed, Pompons, and Japanese Anemones. With groups of Chrysanthemums, Mr. Townsend of Putney won the chief prize for a well-arranged and varied collection, Messrs. Hunt and Carter following in the order named, but the second prize group, though containing the finest blooms, was disfigured by the stems being tied across each other in front to form a kind of lattice hiding the other stems. The groups of miscellaneous plants were excellent, particularly that from Mr. Luff, which gained him the first place. The Hon. Secretary, Dr. Walker, was as busy as usual, while Mr. J. Lyne conducted the arrangements in his customary energetic but agreeable manner.

TAUNTON.—NOVEMBER 15TH.

IN some respects this was the best autumn Show yet held at Taunton, the improvement being most apparent in the fruit classes. The Committee are all practical gardeners, with these being associated Mr. R. H. Poynter as Honorary Treasurer, and Mr. W. Hockin, Honorary Secretary, and on the whole they carry out their work in a very creditable manner. The attendance of visitors was most satisfactory, and at times amounted to a great crush.

There were a considerable number of classes for trained Chrysanthemum plants, but in few instances only was the competition good, the general complaint being the backwardness of the plants. Mr. C. Lucas, gardener to John Marshall, Esq., Taunton, was first for six specimens of Japanese varieties, all well flowered plants. With six incurved varieties Mr. W. Cavill, gardener to H. F. Manley, Esq., Taunton, was first, but many of the blooms were only half expanded. In the class for four Japanese varieties Mr. C. Burt, gardener to Mrs. C. Meade, was first; and for four reflexed varieties, Mr. C. Way, gardener to J. E. Coulthurst, Esq., took the lead, the exhibits being creditable in each instance. A special

class was provided for six specimens, any varieties. Mr. W. Cavill was well first, having finely flowered plants of Lady Selborne, Fair Maid of Guernsey, Peter the Great, Bouquet Fait, Elaine, and Madame Bertie Rendatler. Mr. C. Lucas was second with smaller but well-flowered plants. Several classes were provided for single specimens, and in these Messrs. C. Lucas, C. Way, W. Cavill, and J. Henley were winners of first prizes. Several groups of Chrysanthemums were in competition, but these were more remarkable for the quantity rather than the quality of the blooms on the plants. Mr. T. Wilkins, gardener to Miss Cleeve, was well first; Mr. J. Desmond, gardener to Colonel England, second; and Mr. C. Burt third.

A variety of other plants were in competition. Mr. C. Lucas was easily first for a mixed group, admirably arranged. Mr. R. H. Poynter was a creditable second, and Mr. J. Durk, gardener to H. J. Penny, Esq., third. The best six Ferns were staged by Mr. J. Parrish, gardener to Mrs. Gorden; and Mr. J. Reed, gardener to E. J. C. Parsons, Esq., was second. For a single specimen Mr. J. Lloyd, gardener to Vincent Stuckey, Esq., Langport, was first, and Mr. J. Parrish second. The first prize for six Poinsettias was awarded to Mr. J. Mockeridge, gardener to J. E. W. Wakefield, Esq., and the second to Mr. J. Parrish. W. H. Fowler, Esq., was first for Cyclamens, and the prizewinners for Lycopods was Mr. W. J. Durk, who was first; and Mr. E. Bradbeer, gardener to W. B. Hellard, Esq., second. Primulas are always a feature at this Show, the exhibits being numerous and good in quality. In one class Mr. W. Cavill was first, and Mr. W. H. Worrall second; and in another instance Mr. C. Cooper, gardener to G. L. Collard, Esq., was well first, and Mr. W. Cavill second.

There was a falling off in the entries for cut blooms, but in nearly every class the winners of the first and second prizes were nearly evenly matched. In the class for thirty-six varieties, eighteen to be incurved and eighteen Japanese, Mr. C. Lucas was first, beating Mr. J. B. Payne, gardener to the Lord Bishop of Bath and Wells, by two points only. Mr. Lucas had remarkably good blooms. Mr. Payne's had exceptionally fine blooms of incurved, and generally good Japanese. With twenty-four blooms, to consist of incurved and Japanese varieties in equal numbers, the competition was equally close; Mr. W. Thomas, gardener to Wilfred Marshall, Esq., who was placed first, and Mr. C. Cooper, the winner of the second prize, both staging grand blooms. Mr. W. Thomas was also first for twelve Japanese varieties, and Mr. C. Cooper second, while for six Japanese varieties Mr. C. Lucas was first, and W. H. Fowler, Esq., second. The first-named had a pretty bloom of Florence Percy and Ralph Brocklebank in good condition. The best twelve reflexed varieties were also staged by Mr. W. Thomas, who had fine blooms of Golden Christine, Cloth of Gold, Dr. Sharpe, White Christine, Cullingfordi, and W. Holborn. Mr. S. Tottle was a good second. Mr. C. Lucas was first for six Anemone flowered varieties, winning with capital blooms of Timbale d'Argent, Thorpe junior, Lady Margaret, Acquisition, Gluck, and Madame Clos. Mr. W. Thomas was a good second. Mr. C. Cooper had exceptionally good Zonal Pelargonium blooms, and was easily first; as was Mrs. A. C. Dyer with a hand bouquet. Vases of cut flowers and baskets of wild foliage and fruit were very poor.

As before stated, fruit was shown in much greater quantities than usual, and the quality was also highly satisfactory.

BRIXTON, NOVEMBER 15TH AND 16TH.

CHRYSANTHEMUM growers in the suburban district of Brixton, Streatham, and Clapham have had many bright and beautiful exhibitions, but never a better one than on the dates named. Plants and blooms were alike excellent, while fruit and vegetables were of superior quality. Only a compressed report can be given indicating the varieties in the chief classes. Two good stands of twenty-four incurved blooms were staged by Mr. Howe, gardener to H. Tate, Esq., Streatham Common, and Mr. T. Sadler, gardener to Mrs. Lambert, Streatham, the former securing the leading position with the following varieties:—Back row—Golden Empress, John Salter, Empress of India, Alfred Salter, Emily Dale, Bronze Queen, Beauty, and Queen of England. Middle row—Princess of Wales, Mr. Bunn, Jeanne d'Arc, Nil Desperandum, Mrs. Weston, Mrs. Haliburton, Lord Wolseley, and Jardin des Plantes. Front row—Mr. Brunlees, Eve, Cherub, Barbara, White Globe, Emily Dale, John Salter, and Pink Venus. In the class for twelve incurved there was great competition, Mr. J. W. Wildman leading with admirable examples of Empress of India, Bronze Queen, Lord Alcester, Queen of England, Alfred Salter, Golden Empress, John Salter, Emily Dale, Mrs. Shipman, Hero of Stoke Newington, Mrs. N. Davis, and Empress Eugénie. The remaining prizes fell to Mr. Howe and Mr. E. Cherry, gardener to Mrs. Gabriel, Streatham, with creditable stands.

There was a splendid display of Japanese blooms; indeed, it is doubtful if finer have been seen than those staged by Mr. T. Mursell, gardener to Mrs. Burton, Streatham, in the first-prize stand of twenty-four distinct varieties—namely, Back row—Gloriosum, Fair Maid of Guernsey, E. Molyneux, Snowstorm, Sunflower, Madame C. Audiguer, Madame Blanche Pigny, and Mrs. C. W. Wheeler. Second row—Stanstead White, Hamlet, Meg Merrilies, Ralph Brocklebank, Val d'Andorre, Album Fimbriatum, Boule d'Or, and La Triomphante. Front row—Maggie Mitchell, Golden Dragon, W. G. Drover, Avalanche, M. Freeman, H. Cannell, Madame John Laing, and Marguerite Marrouch. Sunflower was remarkably fine, and certificated. The remaining prize-winners in the class were Messrs. W. Howe and J. Plumb, gardener to Mrs. Grote, Chapham Common, with highly satisfactory examples. Mr. Mursell was also first in the class for twelve blooms, in which there was great competition with superior examples of Gloriosum, E. Molyneux,

Madame B. Pigny, Mrs. Wheeler, La Triomphante, Fair Maid of Guernsey, Ralph Brocklebank, Meg Merrilies, Sunflower, Hamlet, Madame John Laing, and Marguerite Marrouch; Messrs. W. Howe and T. Sadler following with good stands. Special prizes were offered for twelve blooms staged with stems a foot long, and very effective the stands were, the prizes being won by Messrs. Mursell, Howe and Tate respectively. Anemone varieties were of good average quality, the prizes falling to Messrs. F. Fullbrook, Streatham Hill; F. Saunders, Clapham Common; and D. Gibbons in the order named; the varieties in the leading stand being—Lady Marguerite (2), Margouline (2), Georges Sand (2), Minnie Chate, Gluck (2), Acquisition, Fleur de Marie. Mr. W. Howe secured the chief with reflexed blooms in good competition, followed by Messrs. Gibbons and Sadler. Mr. C. Livermore had the best Pompons.

Specimen plants were well trained, healthy, and bearing good blooms, the prizes for six plants being won by Messrs. J. Weston, E. Cherry, and W. Clarke, in the order named. In the class for Pompons the successful exhibitors were Messrs. Cherry, Weston, and Young, all staging well. Mr. Weston had the best pyramids, and Mr. W. Clarke the best standards. Specimen Japanese plants were admirable in culture and floriferousness, Messrs. Cherry, Weston, and W. Clarke well winning the prizes as named. Ferns were most creditably exhibited, Mr. H. Wright's first prize collection of four plants containing a remarkable example of *Gymnogramma schizophylla*. Single Primulas from Mr. Mursell, and doubles from Mr. Guyett, were unusually fine. Stove and greenhouse plants were well represented, and Orchids from Messrs. Rawson, Guyett, and Howe contributed to the richness of the Exhibition, and Mr. J. W. Silver had a very handsome wreath.

In the fruit classes, black Grapes from Messrs. Hill, Howe, and Wing were excellent, the contest between the two former being exceedingly close; but in the white class their positions were reversed. Mr. Howe staged the best Pears and culinary Apples, and Messrs. Guyett and W. Collins the best dessert Apples.

Vegetables were of first class quality, the prizes for twelve varieties being won by Messrs. Howe, Saunders, and Cherry; and for eight sorts by Messrs. Sadler, Wright, and Parrot. The Show was faultlessly arranged under the experienced superintendence of Mr. W. Hall, the Secretary, aided by willing assistants.

SALISBURY.—NOVEMBER 15TH AND 16TH.

THE Wilts Horticultural Society held its third annual Exhibition of Chrysanthemums and fruit in the Market House on the above dates, but unfortunately was not favoured with fine weather. Groups of plants arranged for effect have become quite a feature at the Wilts Horticultural Society's Shows. Mr. Brown, Portland Place, Salisbury, is a very keen and successful amateur, and on the present occasion he secured the £10 10s. cup in the open class for a group of Chrysanthemums arranged in a semicircle of 10 feet in diameter. Mr. Chalk, gardener to Mr. Reid, Wilton Road, Salisbury, was a good second; his plants and blooms were good, but the arrangement was too formal. Mr. Lovibond, St. Anne Street, Salisbury, was third. In the corresponding class (open only to those who do not keep a regular garden) Mr. Councillor Haskins, Poultry Cross, Salisbury, was awarded the £5 5s. cup for well-flowered plants capitally arranged in a semicircle of 8 feet in diameter. Five good groups of miscellaneous plants were arranged in a semicircle of 10 feet by 6 feet, Mr. Brown again taking first position with an arrangement both graceful and well balanced in colour.

CUT BLOOMS.—The coveted prize of a silver cup, value £10 10s., and a small money prize which was given with each cup as a first prize for twenty-four blooms, was secured by Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury, with a fine solid back row of Japanese, the incurved being of medium size but fresh and well finished. The varieties were:—Back row—Boule d'Or (2), very large; Duchess of Albany, Thunberg (2), Mdle. Lacroix (2), Japonais, Ralph Brocklebank. Middle row—Queen of England (2), Lord Alcester (2), Princess of Wales, Empress of India (2), Alfred Salter. Front row—Barbara (2), Jardin des Plantes (2), Jeanne d'Arc, Princess of Teck, White Venus, and Cherub, the colours being well blended. Mr. Inglefield, gardener to Sir John W. Kelk, Bart., Tedworth House, Marlborough, being a good second. Mr. Flight, Cornstiles, Twyford, was third, showing all incurved varieties, which were rather flat throughout. There were four good lots put up in this class.

In the class for eighteen blooms (open to amateurs only), Mr. Annalls, gardener to Chaloner Shenton, Esq., The Glen, Golden Common, Winchester, winning the £5 5s. cup with fairly good blooms of the following:—Back row—Gloriosum (2), one very fine and deep Baronne de Prailly, Fair Maid of Guernsey, E. Molyneux, Madame J. M. Pigny. Middle row—Cullingfordi, Golden Empress of India (3), Lord Alcester. Front row—Madame C. Audiguier, Prince Alfred, Lord Eversley, Lord Wolseley, and Golden Queen of England, Mr. Councillor Haskins being second; his best blooms being Duchess of Albany and Madame C. Audiguier. Mr. W. Batlen, Old Basing, Basingstoke, was third. In the class for twelve blooms Mr. Fred Griffin, Wilton Road, Salisbury, was first with a good stand. Mr. C. Melhuish, Exeter, was second, and Mr. W. Batten was third.

Fruit was not shown extensively, but the quality was, with few exceptions, excellent. Mr. Warden was first with a collection of six kinds of fruit. Mr. Warden was a capital second. With two bunches of Alicante Grapes Mr. Warden was easily first, with large, shapely, and well coloured bunches, carrying a very heavy bloom. Mr. Chalk being second with large but badly finished bunches. Mr. Warden and Mr. Chalk were again first and second with Muscat

of Alexandria, the former showing good bunches, the berries being of good size, clean, and of a beautiful golden colour. Mr. Warden was first with grand examples of Gros Colman in the class for any other black Grape than Alicante, and in the corresponding class for any other white than Muscat Mr. Ward was first with Trebbiano, similar to those shown in his collection.

CHISWICK.—NOVEMBER 16TH.

SOMEWHAT unfavourable weather militated against a large attendance at the Chiswick Vestry Hall on the occasion of the annual autumn Show, but those who disregarded the unpleasant state of the elements were rewarded by an inspection of a most interesting exhibition. Chrysanthemums were of course the most prominent feature, and to the most important classes devoted to them our remarks must be confined.

Groups (not to cover a space of more than 60 square feet) were arranged by four growers, the local nurserymen, Messrs. Fromow and Sons, securing the first prize. The plants were healthy but small, and the blooms, collectively considered, hardly of average quality. General effect is, however, the object chiefly aimed at in such classes as this, and Messrs. Fromow's plants were admirably arranged. Mr. Mears, gardener to J. T. Thornycroft, Esq., Chiswick, was second, and Mr. Davis, gardener to H. G. Lake, Esq., Chiswick, third. Mr. May, gardener to the Marquis of Bute, showed a fine group, not for competition, which was highly commended. Only one exhibited specimens of large flowering varieties—namely, Mr. Wright, gardener to E. H. Watts, Esq., Chiswick, to whom first prize was awarded. For one trained specimen, any class, Mr. Wright was again awarded first prize, Mr. Picking, gardener to J. Pulman, Esq., Chiswick, following. Messrs. W. Wood & Sons' special prize for twelve untrained plants fed with their liquid manure powder was won by Messrs. Fromow & Sons.

The principal class for cut blooms was that for twelve Japanese and twelve incurved varieties, distinct, and seven stands were in competition. Mr. Coombs, gardener to W. Furze, Esq., Teddington, followed up his previous successes this season by a somewhat easy victory. The Japanese were somewhat weak, but the beautiful condition of the incurved blooms more than compensated for this. The varieties were as follows:—Japanese: Boule d'Or, Edwin Molyneux, Madame Audiguier, Duchess of Albany, Mrs. J. Wright, Comtesse de Beauregard, Gloriosum, Madame J. Laing, Madame Baco, Mr. Garnar, Madame J. Pigny, and L'Ebouriffée. Incurved: Queen of England, Golden Empress, Empress of India, Lord Alcester, Bronze Queen, Mrs. Heale, Lord Wolseley, Princess of Wales, Princess Teck, Prince Alfred, Jardin des Plantes, and Hero of Stoke Newington. Mr. Waite, gardener to Col. Hon. W. P. Talbot, Esher, was second, his Japanese being much neater and fresher than those in the first prize stand, but the incurved were some few points behind. Mr. Munro, gardener to E. J. D. Paul, Esq., Twickenham, was third. The latter won with twelve Japanese, showing Boule d'Or, Val d'Andorre, Baronne de Prailly, Gloriosum, Fernand Feral, Mrs. J. Wright, Comte de Germiny, M. Elliott, Mdle. Lacroix, Japonais, Marguerite Marrouch, and Album Plenum. Mr. Waite showed fresh blooms for second prize, and Mr. R. Wood, gardener to Mrs. Sanderson, Chiswick, was third. For six varieties the prizes went to Messrs. Palmer, gardener to W. F. Hume-Dick, Esq., Thames Ditton; Picking, and Collyer, gardener to Messrs. Murrell, Ealing, W.

E. Sanderson, Esq., St. Mary's Road, Harlesden, N.W., won with twelve incurved. His blooms were very small, but perfect in freshness and finish, forming a charming stand. The varieties were Princess of Wales, Hero of Stoke Newington, Lord Alcester, Queen of England, John Salter, Empress of India, Mr. Brunlees, Mrs. Norman Davis, Jeanne d'Arc, Alfred Salter, Golden Empress, and Princess of Teck. Mr. Coombs was second with much larger but less neat blooms, Mr. Waite being third. The latter won with six reflexed—Mdle. Tezier, Amy Furze, Cullingfordi, King of Crimson, Golden Christine, and Pearl Christine representing him. Messrs. Coombs and Jones, gardener to E. Hyde, Esq., followed. Pompons were best shown by Messrs. Coombs, Collyer, and Chadwick, gardener to E. M. Nelson, Esq., Ealing. The latter was the only exhibitor of single varieties, and was placed first. Mr. Sanderson won with six incurved, any variety, showing Hero of Stoke Newington finely; Mr. Waite being second with Queen of England; and Messrs. Fromow & Sons third with Lord Alcester. In a corresponding class for Japanese the latter firm won with fresh examples of Mdle. Lacroix. Mr. Waite was third with F. A. Davis, the second prize lot not being discoverable. The chief feature of the amateurs' classes were the cut blooms shown by Mr. Sanderson.

Table plants, fruit, and vegetables were admirably shown in many instances, but space does not permit of further particulars.

HUDDERSFIELD.—NOVEMBER 16TH AND 17TH.

THE fifth Exhibition of this Society was held in the Town Hall on the dates named, but the Exhibition was not equal to that of last year. The schedule provided six open classes for cut blooms and twelve open to exhibitors within a radius of seven miles, three of these being specially reserved for local amateurs. In the class for forty-eight blooms, twenty-four Japanese and the same number of incurved, not less than eighteen varieties of each, there were three competitors. Mr. D. Lindsay, gardener to Sir Thos. Edwards Moss, Bart., Otterspool, Liverpool, won by three points with heavy flowers, some of which were slightly past their best. Mr. A. R. Cox, gardener to W. H. Watts, Esq., Elm Hall, Wavertree, was a very good second with smaller but fresher flowers. Mr. Cox took the lead with his incurved blooms by four points, but was seven points behind

with Japanese. Mr. Midgley, gardener to H. Mason, Esq., Bingley, was third with much smaller flowers. The first collection contained:—Incurved—Back row—Empress of India, Prince Alfred, Queen of England, Lord Alcester, Prince Alfred, Queen of England, Lord Wolseley, Empress of India. Middle row—John Salter, Golden Empress, Lord Wolseley, Alfred Salter, Jeanne d'Arc, Emily Dale, Princess of Wales, and John Salter. Front row—Princess Beatrice, Mrs. Heale, Pink Venus, White Venus, Refulgens, White Beverley, Mr. Bunn, and Princess Beatrice. Japanese—Back row—Boule d'Or, Meg Merrilies, E. Molyneux, Ralph Brocklebank, Belle Paule, Golden Dragon, Jeanne Délaux, Stanstead White, a large very fine bloom. Middle row—M. J. Laing, Golden Dragon, Criterion, Meg Merrilies, E. Molyneux, Madame C. Audiguier, R. Brocklebank, and Madame J. Laing. Front row—Avalanche, good; M. Marrouch, Elaine, La Triomphante, Thunberg, Val d'Andorre, Elaine, and Boule d'Or. Three collections were again staged in the class for twenty-four distinct varieties, half Japanese and the remainder incurved. Mr. Cox took the lead with bright fresh flowers, Mr. Lindsay was second, and Mr. Midgley third. In the corresponding local class Mr. J. Henderson, gardener to T. J. Hurst, Esq., Meetham, was placed first with very creditable flowers. Mr. F. Stokes, gardener to Mrs. C. Crosland, Crosland Moors, was second, and Mr. F. Senior, gardener to T. P. Crosland, Esq., Birkley Grange, third; four collections were staged. For twelve Japanese (local) Mr. W. Daniels, gardener to T. Hague Cook, Esq., Mirfield, was well first with large flowers; Mr. J. Henderson followed closely with smaller, slightly fresher examples; third, Mr. J. Turner, gardener to A. Fisher, Esq., Springdale. In the corresponding class for twelve incurved Mr. F. Hatch, gardener to J. F. Bugg, Esq., took the lead. In the open class for twelve large-flowering Anemones, not less than eight varieties, Mr. A. R. Cox was successful, and staged grand flowers; Mr. J. Henderson was second with smaller but neat flowers; Mr. Midgley secured the remaining award.

Bouquets were well represented, as also were stove and greenhouse flowers, miscellaneous plants and fruit.

DERBY.—NOVEMBER 17TH.

THE fourth annual Show of the Derby Chrysanthemum Association was held in the Royal Drill Hall on the date named. Cut blooms were of fair average quality. Several stands of cut blooms were exhibited with stems and foliage, no less than twenty stands of twelve blooms each being staged in this manner. The N.C.S. bronze medal and a money prize for groups brought five competitors. Mr. J. H. Biggs, Derby, being placed first, the plants possessing fairly good blooms. Mr. F. Bancroft, Derby, was second.

For twelve incurved blooms, distinct, the N.C.S. silver medal was offered with a money prize of 40s. Mr. A. H. Fowkes, Northampton, was first with medium sized, even, neatly finished blooms of Golden Empress, Empress of India, Lord Alcester, Queen of England, Alfred Salter, Jeanne d'Arc, Golden Queen of England, Princess of Wales, Mabel Ward, Prince Alfred, Jardin des Plantes, and Lord Wolseley. Mr. Thomas, gardener to W. J. Marshall, Esq., Taunton, was a close second; and Mr. J. Lambert, gardener to Col. Wingfield, Shrewsbury, third.

For twelve Japanese the N.C.S. silver medal and a money prize produced good entries. Mr. Thomas was here successful in winning first honours with medium-sized fresh blooms. Boule d'Or, Meg Merrilies, Madame C. Audiguier, Fair Maid of Guernsey, Edwin Molyneux, Baronne de Prailly, Ralph Brocklebank, W. G. Drover, Madame J. Laing, Japonaise, Belle Paule, and Duchess of Albany. Mr. J. Lambert second, and third Mr. Fowkes. The following classes were for members only. For twelve incurved, not less than eight varieties, Mr. F. Bancroft, Derby, was first with neat blooms staged with stems 8 to 10 inches with foliage attached. Second, Mr. C. Carrington. For twelve Japanese Mr. W. Boyes, Milford, was well to the front, Mr. F. Bancroft second, he also staging some good flowers. Mr. F. Bancroft staged also the best six reflexed blooms. For the best bouquet of Chrysanthemums Mr. J. H. Goodacre, Derby, was easily first with a neat arrangement in which the small white Pompon Snowdrop was effectively used. Mr. E. Letchford, Derby, was second.

Messrs. R. Smith & Co., Worcester, staged fifty dishes of Apples and Pears in good order, being rich in colour; these and thirty dishes of seedling Potatoes from the Speciality and Novelty Co., Newton-le-Willows, Lancashire, were "not for competition."

KITCHEN GARDEN.

THE VEGETABLE SUPPLY.—The supply of winter vegetables is turning out remarkably well. In July and August, when most of our winter crops were much behind their usual form, we felt doubtful as to the winter supply being sufficient, but September and October assisted them wonderfully, and now we have better winter vegetables than we had at this time last year. In some seasons our Savoys have been too early. They have hearted and begun to burst by this time, but this year we sowed the seed three weeks later, and they are now right. We

have discontinued growing Drumhead Savoys, as they are too large and coarse. Green Globe is also inclined to coarseness, but those of the Tom Thumb type are of good quality, and it is these and the Reading Express that we have this season. Brussels Sprouts, than which there is no more useful vegetable, have been sprouting freely of late, and although they are not so large as we have had them, they are firm and choice. Broccoli for midwinter are well advanced, winter Spinach is luxuriant and plentiful, and Salsify and Parsnips are full grown. Parsley is most abundant, and we feel capable of meeting all demands, but though others may be as favourably situated, and we hope they are, everything should be used with care, as at present there are indications of a severe winter, and should this happen all may be wanted before Easter. The man that serves the kitchen for us has strict orders to use the most forward first, and this is a rule to which there should be no exception.

YOUNG VEGETABLES IN FRAMES.—The absence of sunshine and the long nights are now making Cauliflower, Radishes, Lettuce, Endive, and such vegetables in frames appear pale and lifeless, and they will not grow much more after this time; but they are apt to suffer more from damp than cold air, and as much as possible of the former should be excluded from them. If the soil is saturated, get some dry sand and sprinkle a little of this over the surface between the plants. Make the lights watertight and keep them closed during damp weather, but withdraw them when the sun shines, and when the air is dry tilt them up on the sheltered side. When once the plants become accustomed to the winter weather they will cease suffering much from it, and it is to inure them to this that a little extra attention should be devoted to them now. When once frost reaches plants so as to make any of the leaves soft, it will be a most difficult matter to keep them in good health afterwards.

FORCING RHUBARB.—Rhubarb is the first of the kitchen garden roots that will force readily, and when ready by Christmas or earlier it is much valued on the table or in the market. Those who have to make the most of their gardens, not only in supplying their employer's table but in sending to market, would find plenty of Rhubarb if ready in December a very remunerative crop, and this is more than can be said of it when it becomes plentiful in spring. In the majority of gardens there are always surplus Rhubarb roots. Indeed we have often been sorry to see so much ground given up to this crop, as a few roots will produce as much Rhubarb as is wanted in any house, and now is the time to make good use of the surplus. They may be forced in various ways with little expense. A heated Mushroom house will bring them on rapidly. They may also be forced in Cucumber pits, beds near flues or in frames on the top of hotbeds. In all cases the roots should be lifted entire, put close to the heat, and covered with soil. A bottom heat of 80° will cause them to grow freely. The top growths should be kept in darkness to blanch them, and water should be applied to prevent the soil becoming too dry, but it should not be kept in a saturated state. When forced in frames, the lights should be kept covered, or wood shutters may be used. Rhubarb may also be forced in the ground by turning a cask or box upside down over the crowns, and covering the whole with a hotbed, but this is a system that can be much more successfully practised in spring than in autumn or at midwinter, and we do not recommend its being followed at present.

GLOBE ARTICHOKE.—Of late we have been cutting many good globes which formed after the first crop was cut, and we have still small ones to use, but the plants are showing signs of disliking the cold weather, and as they should not be injured by frost, a good layer of long manure and leaves should be put round the stems of each plant at once. They will continue to die down after that, but the frost will not do them any harm, and all that are covered up will be sure to come up again in good time next spring.

CABBAGES FOR SPRING.—Many like to see their Cabbages for the spring begin to head about this time, as they think when this is the case they cannot fail to be very early, but we are of a different opinion, and we have generally noticed that the plants which head a little in the autumn or early winter are the worst and latest in spring. This can be explained. The part which forms the head of a Cabbage is always more tender than the green or outer leaves, and those which begin to head now soon become so tender in the centre that a few degrees of frost or a fall of snow that lies for a time affects this part far more than the hardy green leaves, and after a thaw the young heads generally appear as if they had been scorched or scalded. It is this which throws them back and makes them really less early than later autumn plants in spring, and no attempt should be made to force Cabbage at this time by applying any artificial manure. They will be benefited, however, by treading the soil very firmly round the necks of each plant, and drawing the soil well up to them with a drag hoe. Blanks in the rows may still be made up, and any very early plants that are seeding should be thrown away, as under no circumstances will they ever become valuable.

TRENCHING AND DIGGING.—Our motto is to keep every quarter full as long as possible, but empty spaces will occur now, and as soon as they do trenching and digging should be begun. Shallow soils or soils with a stiff subsoil will be benefited by being trenched to a depth of 1½ or 2 feet, and all kinds of soils should be dug up and left rough and open on the surface. The frost and air will penetrate to a considerable distance and prove of great advantage. We do not approve of leaving all undug until the spring.

PLANT HOUSES.

Amsonia calycina.—Where this plant is throwing up its bright crimson Poinsettia-like bracts do not attempt to retard it. It does not

appear to bear this treatment without direct injury. The plant itself appears capable of bearing many hardships before it finally succumbs, but during active growth or the production of its inflorescence it must have brisk heat, or else it fails to develop properly. Be careful also not to overwater it. While growing liberal supplies are necessary, but during the present time water must be applied with great care. The roots perish quickly in wet soil and a low temperature. After flowering the plant should be kept on the dry side until it is again started into growth.

Anthurium Scherzerianum.—Plants that have completed their growth should be removed from the stove to an intermediate temperature. While in this position give them less water at their roots. Plants that are still growing should be encouraged to complete their growth in the stove, when they will be benefited by a lower temperature. *A. ferriense* and *A. Andreanum* should be encouraged to grow by keeping them in the stove, they will produce their bright flowers throughout the winter and prove attractive either in a cut state or for the ornamentation of this structure. These varieties will need less water, but be careful not to allow them to suffer by an insufficient supply.

Alocasias.—These will need less water at their roots than has been necessary up to the present time, but on no account allow them to become dust dry, which is injurious, and would soon result in the destruction of their beautiful foliage. Watch for red spider now that the supply of moisture has been diminished. If the plants stand in a rather dry position it often proves troublesome. The best means of keeping the plants free is to sponge their leaves occasionally with a weak solution of soft soap and water, or a weak solution of any favourite insecticide.

Echynanthus.—Where these plants are grown suspended in baskets from the roof of the stove they should be thoroughly cleaned. Much injury is often done if cleaning is delayed until their flower buds are visible. All the varieties are subject to mealy bug, and this must be eradicated from them if they are to display their full beauty. Do not overwater them from the present time; in fact, they are better kept on the dry side, or else they will fail to grow satisfactorily again in spring.

Aphelandra aurantiaca Roezli.—Although useless for cutting purposes this is a charming plant when well grown, either for the front of the stove or for associating with warm Orchids during the time it is in flower. It is perhaps most effective in the latter position. This plant enjoys heat and moisture, especially during the season of growth, but after flowering keep it rather dry until cut back and started again into growth. The usual practice is to increase the stock by cuttings, but the most vigorous plants are raised from seed. Seed is readily saved if a few plants are reserved for the purpose and kept during flowering in a slightly drier atmosphere. Some of the latest plants to flower should be reserved for this purpose. Plants that will flower towards the end of January if well cared for are certain to seed freely enough. Watch for thrips, which is a great enemy to this plant.

Eranthemum Andersoni.—Few plants are more beautiful with their delicately spotted Orchid-like spikes of flowers when well grown; they are most effective when grown in 60's with one shoot only. Be careful to keep the plants free from brown scale and thrip; keep them moderately near the glass in a temperature of 55° to 60°. While in flower the plant is at home in warm conservatories, and if slightly elevated above surrounding objects shows itself to advantage. It is also very useful for small vases in rooms, and although it does not last long in such positions dwarf well-furnished plants have a choice appearance and add variety to the usual class of plants employed in such positions.

Cissus discolor.—This is often grown for its beautifully marked foliage, which can be used for such a variety of decorative purposes. Where this is the case it is advisable to have two plants and encourage one to growth throughout the winter, while the other can be dried off and rested. Keep plants going to rest rather dry until their foliage naturally ripens, when it will be necessary to prune the shoots well back.

THE BEE-KEEPER.

NOTES ON BEES.

THE PECULIARITIES OF THE SEASON.

SINCE the cold wet summer ended we enjoyed really fine weather with but two intervals of a few days until the 16th November, when one of the severest storms raged that we have ever experienced, at least so far as can be judged by the amount of damage done. We had 7° Fahrenheit of frost early in October, the thermometer standing at 25° on the morning of the 7th, but it did little or no damage to flowers. The Mignonette is as pretty while I write as it was at the beginning of August. *Lilium auratum* bloomed until the end of October, but not a *Gladiolus* flowered; and Sweet Peas, although growing freely, did not give more than a dozen blooms. *Helianthus multiflorus flore pleno* is still good with me. *Erigerons* and *Doronicums* are also attractive, while the double blue *Hepaticas*, double and single *Primroses*, and

Polyanthuses have been blooming for the last two months. *Pyrethrums*, from which we expect many autumn flowers, did not grow after the first bloom was past, and notwithstanding the fine weather during September and October, Strawberry plants showed but little growth. Fruit trees and bushes of all kinds lost their leaves early, and it is to be hoped that the thickly set buds on short growths will be perfected and bear much fruit in 1889. With the exception of a few days' cold east wind in November the thermometer was never below 32°, and once only at that. The mean temperature during the end of October was as high as 55° on several occasions, and one day it varied only 2° in twenty-four hours, being 48° at night and 50° during the day. Bees carried pollen well up to the 15th November. Altogether it has been a peculiar season, and untoward as it has been, many bee-keepers have secured an average return of honey—i.e., those who managed their hives on the lines so frequently advocated in these pages.

VARIOUS ITEMS.

I have read with much interest "A Hallamshire Bee-keeper's" remarks at pages 457-58, and can endorse much of what he says, but he is somewhat mistaken in my opinion regarding the "long idea hive." I have many faults to find with it. I noted these in an article several years ago, and still maintain that combs parallel to the entrance are a great mistake, and that it is contrary to the nature of bees to have them so.

In regard to taking such hives to the Heather, I stated fact, leaving your bee-keeping readers to judge for themselves which hive was the one most to be relied upon. Both sorts of hives had combs of the current year, and, as is the case in many instances, they had to be carted over a rough road, which may make all the difference between his case and ours. My cheap hive is the ideal one of "A Hallamshire Bee-keeper." As some of your readers may wish to build up a few of these during the winter months, the following will give an idea of what is wanted. As is already known, the hive proper consists of three or four body-boxes 6½ inches deep, and 14 inches square, inside measure. The stand is of the same size, but only 4 inches deep, with angled iron feet 8 inches over all. The alighting board is either hinged or held by two wire dowels, so that in transit it can be removed or folded up so as to occupy little space. The top is covered with perforated zinc, five holes to the inch. The bottom has a close-fitting shutter resting upon fillets, and a small opening is left in the centre of this shutter, which is again covered with a sliding shutter, stopping itself against a screw. This can be opened and closed in an instant, as also can the doorway. Every division, including the stand, is hinged at the back with back-flap hinges, and fastened at the front or sides with a proper hook or clamp of some sort. When sections are used and suspended to top bars, which is decidedly the best way to have and to work sections, the division holding these is also hinged, and for convenience sake is the same in every way as the body boxes. The first thing wanted when the hive is so arranged is a clamp (one does for the apiary) made from stout hoopings the width of the hive, with the ends turned down to a right angle from 2 to 3 inches, and a slot in each end, so that when a screw-nail is put in at each end when the clamp is held in its proper place, it will slide out and in easily. This will prevent the frames or sections falling out. To make the clamp more rigid screw a fillet of wood to its under side. When any manipulation is desired, or inspection wanted, undo the front hooks and turn the division back. If it be in sections the whole of them can be seen at a glance, and their state will advise the bee-keeper to proper action. The body divisions are inspected in the same manner, care always being taken that bees are not killed on letting down the division. A little carbolic acid will prevent any bees being killed if properly applied to the edges. When cutting out royal cells, or searching for the queen, begin at the bottom box first and work upwards. A stool with a few blocks of wood at hand will be found useful in all manipulations of this sort.

I quite agree with "A Hallamshire Bee-keeper" anent bees

inclining to sting when (as he described lately) Stewarton divisions are turned up bodily and boldly. I also agree with what he says about Cyprians at page 457. A crusty old man was bitten by a dog, and on the owner being informed of it replied:—"If I were a dog I would have bitten him too." So if I were a bee I should be inclined to sting many that I see manipulating bees. Cyprians unmolested are mild in temper, so much so that a little girl of mine when only four years of age could not be kept from peering into the entrance of a populous hive to learn whether the "wee bees had een", and how they could see to work in the dark," and yet she never got a sting. Syrians are at times spiteful, but are easily subdued.

I have had hundreds of imported queens, and once only did I receive a virgin one, a Syrian. I have, however, had numerous complaints from persons of virgins or crossed queens having been put into their hands, but I could invariably trace the disappointment to their own work.

Reverting to the cheap hive, your readers will observe that it is not only a first-class hive for moving about, but cannot be surpassed for general management and ease of manipulation in all that pertains to bee-keeping. It is true it is not defended from the weather, but this is no objection, as double-cased hives are objectionable in many ways, while the single-cased ones are easily and cheaply defended—defending the bees against that insidious enemy damp (if protected from the rain) better than any double-case hive can possibly do, while it is at all times trim and tidy in appearance, and with the hinge arrangement becomes the most useful hive extant, at a cost of only a few shillings when made by the bee-keeper. I may before closing observe that the hinges might be more serviceable if made with a moveable pin, and that clamps or hooks can be easily made from hoop-iron if a bowster punch or a brace with a few twist drills be in the possession of the bee-keeper; or to go a little further, if gardeners were supplied with these and put them to a proper use they would save many a tradesman's heavy bill. Should any of your bee-keeping readers require more details regarding the hive described I shall be glad to explain it fully, as, like the correspondent above referred to, I am of opinion that moving bees about from one pasture to another will every year become more common, so that the weighty and cumbersome hives must give way to lighter ones.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Dicksons (Limited), The Nurseries, Chester.—*Catalogue of Forest and Ornamental Trees, Evergreens, &c.*

The Thames Bank Iron Company.—*Illustrated Trade List of Boilers and other Heating Appliances.*

Kelway & Son, Langport.—*Wholesale List of Gladioli.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (E. T. H.).—Messrs. Stuart & Mein, 15, N.B., is the address you require.

Herbaceous Plants (W. B.).—We shall shortly publish notes on herbaceous plants that will possibly be of service to you. Early spring is the best time for planting the majority of such as you appear to require.

Glass (G. R.).—You appear to have proved the matter for yourself, and cannot err by acting on your own experience. Either kind will answer your purpose, but one is considered somewhat stronger than the other. Mr. Philip Ladds uses the cheaper of the two kinds by the acre.

Canterbury Bells (N. C.).—Plant them out at once in light moderately rich soil in an open situation, but sheltered. The plants being small we should not allow them more than 6 inches' distance apart every way, otherwise they require a foot distance apart. They grow from 18 to 24 inches high, and flower from May to July.

Chrysanthemum Sport (Thos. Winkworth).—The yellow sport from the primrose Ralph Brocklebank is decidedly brighter than its prototype, but the example you send of this is paler than many we have seen. By all means send the new comer to the meeting of the National Chrysanthemum Society as you propose for examination by the Committee.

Show Report (A Twenty-years Reader).—We are obliged to you for the report, as we are to other gardeners who forward notes on exhibitions in their districts. So far from "praising yourself," it is questionable if you have done justice to your products. It is not as a rule strong men who win that coveted much praise for the examples of their skill.

Plants for the Rockery (G. T.).—We shall be in a better position to assist you in this matter if you will state whether the rockery you wish to cover is fully exposed to the sun or in a shady position. This makes all the difference in the selection of plants. We presume your object is not only to cover the rockery, but make it as attractive as possible. If you write to us again we shall be pleased to assist you.

Horn Shavings as Manure (J. E. O.).—The fine shaving and dusty particles referred to are good for mixing with soil for various kinds of plants. The quality of the soil has to be considered in determining the proportions of fertilisers to be added. A 6-inch potful of the shavings to a barrowful of soil would be quite safe. This fertiliser is not quick and powerful in action, but rather steady and lasting in effect. You may try a little more for a few plants, and thus ascertain by experiment the right quantity to use with your soil.

Pruning Vines and Fruit Trees (W.).—Vines should be pruned as soon as the leaves can be shaken off them. You may prune your Apple, Pear, and Plum trees at once. We quite fail to understand the condition of the Vine. You say you "were advised to put as much of the rods as you could out of the top window of the greenhouse in September, so that now there is only one-fourth of the length of the rods left in the house." We did not advise you to adopt such an unusual course, and we shall be surprised if your Vine is improved by the treatment to which it has been subjected. Your adviser, whoever he may be, ought to be able to tell you what to do next. We are, however, quite willing to do so if you make the case clear to us, though we decline all responsibility for the results that may accrue under the circumstances.

Plum Trees Losing their Leaves in July (H. B.).—Whatever may have been the cause of the leaves falling prematurely last year, drought could scarcely have been the origin of the evil this year, especially as the soil and subsoil appear to be of a heavy and retentive nature. Are you sure that insects were not the agents of the mischief? We suspect they have had something to do with it. Your remarks that several of the Apple trees did not produce blossom suggest that the roots of your trees generally have penetrated into the subsoil, where they do not find the necessary support for perfecting good growth, including substantial leaves for elaborating the crude sap and secreting nutrient matter in the stems. If your trees are young we should carefully replant them, placing the roots in good soil, and mulching with manure for keeping them there. If too old and large for this we should remove some of the soil, add fresh, and mulch as advised for inciting the production of active fibrous roots near the surface. If you secure and retain a network of fibres there your trees will steadily improve, and retain their foliage if attacks of red spider and other insects are prevented. Dressing the stems in winter is not a safeguard against insects infesting the leaves in summer.

Vines for Planting (Somerset).—You are wise in planting Black Hamburgs chiefly under the circumstances. Foster's Seedling is the best grower and most certain bearer of white Grapes for ripening about the same time, though the Buckland Sweetwater produces larger berries. You might plant one of each, and if one of them fails to give satisfaction remove it and train up an additional rod from the other. They are suitable for an outside border. A Madresfield Court might succeed at the warmest and driest end of the house, but if not it could be removed and a second rod could be trained from a Black Hamburg for occupying the roof space. A well supported Vine will sustain a crop on two rods as well as on one only. Shorten the Vines as soon as you receive them this autumn, and keep them in a very cool place through the winter, not allowing the roots to get unreasonably dry. As a rule, the more planting canes are shortened the better is the growth the first season, and it will be well to cut back to the lowest bud that will be in a light position in the house. If after planting in spring you find you have not pruned low enough, do not shorten

the cane then, but rub off some of the top buds as may be required. Leaving the canes their full length when planted is the cause of not a few failures in Vine growing.

Raising Gladioli from "Spawn" and Seed (Bristol).—We know of no special treatise such as you appear to require. "D., Deal," has often described the raising of plants from bulbets or "spawn." We have raised thousands by sowing the bulbets thinly in drills a foot apart and about 2 inches deep in free soil in the open ground in March, not disturbing the plants till a few of them flowered, then when these die down taking up the whole and sorting the corms into sizes for planting. Many seedlings have been raised by sowing in boxes of sandy loam in a frame in the spring, but a simpler plan is to sow the seed as if it were Onion seed in the open ground. Mr. J. Ollerhead of Wimbledon described his practice and the results in our columns in January of last year, and as the number is out of print his remarks are reproduced:—"Most soils will grow matured corms with a certain amount of satisfaction, even under very ordinary management; but to succeed well with seed a good friable soil is indispensable, and this should be well drained, either naturally or artificially, to carry away all stagnant or superfluous moisture which may be caused by the constant waterings necessary during the growing season. Trench and manure the ground in the usual way, except in securing some of the best decayed dung available, and keep it near the surface to feed the seedlings immediately they begin to root. I sow our seed in a well-prepared border in the kitchen garden, and as we are close on a gravel subsoil we can water our plants freely, without fear of stagnation. I sow the seed in drills about 8 inches apart (just wide enough to work a Dutch hoe with freedom) about the middle of March, if the weather is favourable; if not, I leave it to the end of March. Immediately the seedlings appear keep the ground well stirred with the Dutch hoe to keep down weeds. Immediately the ground seems dry and sweet, give them a good watering with liquid manure. Even at this early stage of growth they will take liquid twice or thrice a week if the weather is dry, and as they advance in growth they will take it more abundantly—in fact, the only attention they will require will be a perpetual stirring of the soil to break the crust formed by watering, which will also keep down weeds and give abundance of liquid manure, and if this is persevered in I am quite satisfied the cultivator will be rewarded with a few spikes of flower in the same year the seeds are sown; at any rate, the writer has flowered them the first season from seed, and I see no reason why other cultivators cannot do likewise. I remember several years ago, paying a visit to Mr. Kelway at Langport. When I arrived he expressed his pleasure in seeing me, and added, 'I have a treat in store for you—a field over a quarter of a mile long of Gladioli in full bloom.' And it was a sight well worth going to see, and this was only one of the many fields he had at that time in full bloom. While enjoying this great feast of Gladioli bloom, Mr. Kelway remarked, 'I am the only successful Gladioli grower in this country—i.e., a cultivator who grows the plant from seed to maturity in this country,' and I thought he well deserved the palm. I noticed his seeds were all sown in drills, and he told me how long it took to mature the corms to flowering size, and feeling as I did so deeply impressed with the sight of acres and acres of their flowers, I determined to try my hand in working up a stock. Accordingly I secured some good named varieties to start with, saved seed, sowed it, and grew the seedlings in the manner I have described, and, as I have already stated, succeeded in flowering some of the seedlings in the same year they were sown." This record of successful practice can scarcely fail to be of service to yourself and the other "feverish amateurs" in your neighbourhood.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (T. S. B.).—1, Red Calville; 2, King of the Pippins; 3, Cox's Orange Pippin; 4, Brimwood Pippin. Pear is Belle Epine du Mas. (J. Lansdell).—1, Braddick's Nonpareil; 2, Not known; 3, Scarlet Nonpareil; 4, Not known. (F. L.).—1, Beurré Bosc; 2, Hacon's Incomparable; 3, Beurré Diel (Beckenham).—The Apple is certainly not Blenheim Pippin, but Hornet Pearmain. (Jos. Harrison).—1, Hawthorndean; 2, Cellini; 3, Winter Greening; 4, Northern Greening; 5, Golden Reinette; 6, Bedfordshire Foundling. (Fisher).—1 and 2, Goff; 3, Braddick's Nonpareil; 4, Golden Streak; 5, Golden Winter Pearmain; 6, Beurré Diel. (F. J.).—1, Thompson's; 2, Due de Bordeaux; Nos. 3 and 6 tickets were loose in the box; 4, Beurré Superfin; 5, General Toddleben.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (G. M.).—We much regret that owing to the flowers being very small and being packed in paper they were so shrivelled when they reached us as to be quite beyond recognition. The delicate flowers of Orchids require especial care in packing when they have to travel even a short distance. (W. R.).—1, Adiantum gracillimum. 2, Adiantum zethiopicum. 3, Nephrolepis tuberosa. 4, Selaginella Martensi. (R. O., Sheffield).—1, Pleione Lagenaria. 2, Lælia anceps. (G. H.).—1, The

Abutilons are apparently seedling varieties. 2, Adiantum pedatum. 3, Too imperfect to be recognised. 4, Davallia canariensis.

SHEEP MANAGEMENT.

THE importance of sheep as a factor to success in farming has obtained more general recognition, and has been turned to better account than most other points of good husbandry. But like other good things it is liable to abuse, and there can be no doubt that there is a serious annual loss of sheep through carelessness or mismanagement. Perhaps our most considerable losses occur among ewes and lambs, and it cannot fail to be useful to call attention now to some of the causes of such losses, upon the sound principle that prevention is better than cure.

To have strong healthy lambs it is of primary importance that the ewes are well bred and well fed. Careful attention to diet

only while the lambs are with them with not suffice; they must be kept in good condition the year round if their progeny is to be as robust as it ought to be. Let us see how this can be done. When the lambs are weaned in June the ewes are turned upon pasture that is poor rather than rich, the object being to keep them upon a low diet till milk ceases to flow, and the risk of swollen, sore, or broken udders is past. By that time, too, any wounds caused by the wool-shearing will be healed, and they are dipped in Cooper's Dressing, which not only destroys ticks and other insects, but renders the sheep comparatively safe from the attacks of fly during the hot summer months. However well and carefully we may feed suckling ewes, a strong lamb or twins will bring down condition, and we must try and restore it as soon as may be, for the ewes have barely two months before they are again put with the tups. Upon arable farms they are folded upon Tares, Clover, Sainfoin, Lucerne, or Mustard, and where there is sufficient pasture nothing can be better for them than a full diet of grass. They receive no other food till after harvest, when they are taken upon the corn stubbles. Some care is requisite in doing this, more especially upon Barley stubbles, for the sheep eat the corn so greedily that losses occur from stoppage if they are allowed to eat the fallen ears of corn to repletion.

With the exception of the stubble corn they have nothing but green food, nor do they require it till a month before lambing begins, when they receive half a pound of crushed Oats per head daily. After the lambing, and till the lambs are weaned, the quantity of crushed Oats is increased to a pound per head daily. A piece of rich pasture is kept in reserve specially for the lambing, and there is a careful addition to the dietary of Mangolds, chopped Barley or Oat straw, and Pea straw in racks according to the weather and condition of the pasture. Cattle Cabbage and silage may then be included in the dietary with advantage, but neither white Turnips nor Swedes are used till after the lambing. We never allow pregnant ewes to be folded on Turnips, knowing how frequently the practice leads to serious losses of the ewes, and also of lambs by abortion. The evil of such folding is threefold. The effect upon the ewes of the consumption of large quantities of food containing so large a percentage of water—80 per cent—always then at a low temperature, often half frozen, is to lower the temperature of the body to a degree that is hurtful to the ewe, and often fatal to the foetus. The second evil arises from the strain made upon the animal in making its way through the muddy fold where the soil often becomes churned into mud, reaching half way or more up the sheep's legs, and in heavy land such mud is so tenacious that they can hardly withdraw their legs from it, and certainly cannot lie down to rest, for if they were to do so they would hardly be able to get up again. The third evil is the exposure and the heavy strain upon the entire system of the ewe precisely when it requires protection from everything at all calculated to prove injurious to health. No doubt the sheep is a hardy animal, but there are limits to its powers of endurance, and it is wiser by far, instead of running the risk of loss from such exposure, to avoid it, at any rate to a hurtful degree.

Before proceeding farther with ewe treatment, we may usefully here revert to the question of dipping. No doubt the dipping should always be done in summer after the shearing and weaning, both to ewes and lambs as we have explained, but it is by no means so certain that there should be a second dipping in autumn. We have had it done with material advantage when the wool is at all infested with parasitical insects, and this can be ascertained by a close inspection and a little watchfulness. We once purchased a flock of sheep so late in the year that dipping was out of the question, yet they were so badly infested with ticks that they were constantly rubbing themselves, and they did not get into a thriving condition till we were able to get rid of the ticks, which was not for some months.

(To be continued.)

WORK ON THE HOME FARM.

The wisdom of keeping a fair proportion of the land under Wheat is well illustrated just now, for most of the Barley was so much discoloured by the rain which fell so frequently after the grain was fully developed, that prices are exceptionally low. The highest price we have obtained is 32s. per quarter. We have a large quantity to sell, and put our average price for it as low as 26s. This to us is a serious matter, yet we have the satisfaction of being able to sell good samples of white Wheat at from 36s. to 40s. per quarter. Much care and caution has to be exercised in Wheat threshing now, and any stack where the corn proves at all soft should not be threshed till spring. This may eventually prove advantageous, for prices are almost certain to improve with the advance of the season. Those who possess facilities for kiln-drying corn will certainly find it answer the purpose now when hard foreign Wheat is from 6s. to 8s. per quarter higher than home grown Wheat.

As the sowing of winter corn is finished the ploughs are put upon other land in order to get as much as possible ploughed before severe weather sets in. Some land ploughed during harvest has now been cross-ploughed with doubled breasted ploughs and thrown into ridges, where it will remain till it is required either for spring corn or roots. Land that is so treated now always comes to hand in splendid order in spring, and the process of sowing spring corn in it is a speedy and satisfactory undertaking. It is said that land so exposed to the influence of winter weather loses a certain or uncertain per-centage of nitrogen. If this be so, the advantages, on the other hand, are so great that autumn culture commends itself to all good farmers. Only have sufficient drainage to carry superfluous moisture off quickly, throw up the land roughly to expose it to the action of the weather, and we can then easily and profitably restore any small loss of fertility. Economy is good, by all means let us practise it, but depend upon it there is very little to be gained in trying to reduce loss or gain upon the land to fractions. A little common sense here is just as desirable as it is in most things; do not let us forget this.

WEBB AND SONS' ROOT CROP COMPETITION.—A large number of agriculturists competed for the valuable prizes offered by Messrs. Webb and Sons, of the Royal Seed Establishment, Wordsley, Stourbridge, for roots grown from their seed and with the aid of their special manures. Mr. Edward Bennett, farm steward to the Right Hon. the Earl of Dartmouth, Patshull Farm, Wolverhampton, who officiated as Judge, has made his awards as follows:—Class 1.—For 5 acres of Webbs' Imperial Swede grown with the aid of Webbs' special manure in the counties of Salop, Hereford, Montgomery, Stafford, Warwick, Oxford, or Leicester. First prize, value £15 15s., Mr. A. Streeton, Wiehnor, Burton-on-Trent; weight per acre, 37 tons, 0 cwt., 2 qrs., 24 lbs. Second prize, value £10 10s., Mr. W. Humphreys, Evenall, Oswestry; weight per acre, 31 tons, 5 cwt., 2 qrs., 24 lbs. Third prize, value £5 5s., Mr. F. Kibbler, Wellesbourne, Warwick; weight per acre, 31 tons, 5 cwt. Class 2.—For 3 acres of Webbs' Mangolds—any one variety—grown with the aid of Webbs' special manure in the same counties as class 1. Prize, value £5 5s., Mr. R. Harvey, Darlaston, Stone; weight per acre, 45 tons, 13 cwt., 2 qrs., 8 lbs. Class 3.—For 5 acres of Webbs' Imperial Swede grown with the aid of Webbs' special manure in the counties of Worcester, Gloucester, or Cheshire. First prize, value £10 10s., Mr. A. G. Potter, Leigh Court, Worcester; weight per acre, 35 tons, 5 cwt., 2 qrs., 24 lbs. Second prize, value £5 5s., Mr. A. Hoeknell, Newtown, Audlem; weight per acre, 30 tons. Class 4.—For 3 acres of Webbs' Mangolds—any one variety—grown with the aid of Webbs' special manure in the counties as class 2. Prize, value £5 5s., Mr. J. Pocock, Twigworth, Gloucester; weight per acre, 58 tons, 18 cwt., 2 qrs., 8 lbs.

REMARKS.

11th.—Dull, foggy, and damp throughout.
 12th.—Dull cloudy day, wet evening.
 13th.—Fair morning, with occasional gleams of sun, bright afternoon and night.
 14th.—Fine and generally bright.
 15th.—Dull and rainy.
 16th.—Overcast and windy morning, slight shower about 2 P.M., fine afterwards.
 17th.—Fine and generally bright day, shower in evening. Fine lunar halo & midn't t.
 A cloudy and rather damp week. Temperature 8° above that of the preceding week, and 6° above the average. This is the greatest excess in any week since February.—
 G. J. SYMONS.

THE VINERY IN WINTER.

A WEEK rarely passes in which questions relating to Vines are not sent to the Editor, whose guidance is sought on various points connected with their management. This shows, if anything can, that well as Vine culture is admittedly understood by many persons, there are still more in doubt as to the best methods to pursue for gaining the desired end—healthy fruitful Vines and fine bunches of their coveted fruit. It is not for teaching the learned that the *Journal of Horticulture* exists, though these delight in its pages and enrich them by their contributions; but for conveying information that may be of service to the inexperienced, whether these are gardeners in difficulties, and whose livelihood depends on the surmounting of them, or amateurs whose gardens give them pleasure, and not the less because obstacles are occasionally met with and overcome. It is wonderful how much enjoyment can be derived from a vinery by those who delight in growing Grapes when all goes right; but on the other hand, when things go wrong in some perplexing way, the anxiety is correspondingly great. The real lover, not of Grapes as such, but of growing them, takes pride in his Vines at all times—in winter as well as in summer. He can see in the hard brown canes, bold firm buds, pithless wood, and general cleanliness much to admire, knowing that such conditions are precursors of success.

Good work can be done in the vinery at this season of the year, and ought to be done without needless delay. It may not be so urgent that important outdoor work should be neglected when the weather is favourable for its prosecution; but days unsuitable for profitable outdoor occupation have not usually to be long waited for at this period of the year, and when they occur prompt action should be taken to put Vines and vineries in order for the winter and spring. The work here should be thorough as regards cleanliness, more especially when the Vines have suffered from the attacks of insects, no matter of what kind, in the summer. Those pests are to a large extent the outcome of neglect or inaction on the part of cultivators in winter. Too many are content with half cleansing their Vines and vineries. Where that most objectionable insect—the mealy bug—is prevalent, as it is in hundreds of vineries, it is not possible for the work of cleansing to be too exhaustive. A mere washing of exposed surfaces is wholly insufficient. Those that are hidden must have at least equal attention, and indeed more time must be spent on them than on the parts in sight. Every chink and nook must be sought for, for these are the hiding places of the enemy. Every particle of refuse, every empty flower pot, every bunch of sticks and matting must be cleared out. Every plant infested at branch or root must be rendered absolutely clean, or it should have no place in the vinery. Clean plants do no harm to Vines, though the Vines often do harm to them; but as the plants are moveable and quickly producible, while Vines are not, there ought to be no difficulty how to act in an apparent conflict between them as regards their requirements. When good Grapes are expected the Vines must be the first objects of consideration; and the better their wants are supplied the better possibly will the plants flourish that are suitable for growing in the structures, and those that are not suitable have no business there, as they cannot be cultivated satisfactorily, and attempts to provide what they need may result in injury to the Vines that are of immeasurably greater value.

"But why connect plants with the subject?" some reader may

ask, on the ground that they are better in houses to themselves, leaving vineries for the production of Grapes alone. Granted, the advantages of the separate system, yet the fact has to be recognised that the combination plan is forced by circumstances on the great majority, and the majority cannot be ignored in or out of Parliament, but has a way of asserting itself and commanding attention. Facts, then, have to be dealt with, and there is no doubt about the existence of this one at least—that where there is one vinery free from plants always, there are twenty crowded with them over the greater part of the year. What, then, is to be done in vineries now under those circumstances? That is what many an anxious gardener—or man in charge of Vines—(for there is a difference), and many a zealous, but not over-experienced, amateur wants to know. They can only be told generally, for there are peculiar conditions requiring peculiar treatment, and obviously this cannot be suggested till the exact circumstances are known. Those, persons, therefore, who do not find what they want in these notes will know what to do—namely, state their case, objects, and means at disposal clearly, and someone will be almost certain to come to the rescue and endeavour to be helpful.

As regards work in the vinery generally which at the same time contains plants, and the leaves of the Vines changing, also more or less infested with mealy bug, as thousands are, are we to wait for those leaves to fall before taking steps to extirpate the enemy? Certainly not. It is true numbers of Vines have cast their leaves, and these cannot be pruned too soon; but many have not done so, as the leaves of not a few are "hanging on" longer than usual this year. When these leaves are turning yellow or brown, and are at the same time supporting insects, it may be in myriads, they should be taken off and burned. Allowing the leaves to wither and fall, as is customary, amongst plants or on the floor or stages, is the best possible way of distributing those insects and of insuring a greater abundance of them another year. Not one infested leaf should be allowed to fall, but before they wither sufficiently for that, all should be removed, not tearing away the stalks entirely, but snapping off the leaves alone. In this way a horde of insects may be cleared away, and more execution done in an hour than can be accomplished by days of after labour when the insects are allowed to be scattered in the house. Some persons hesitate to remove the changing leaves lest the Vines may be injured or deprived of something which it is vaguely thought the leaves secrete in them. There are no substantial grounds for any such fear of injury resulting from taking off the leaves a week or so before they would fall naturally. They have done their work then, and the removal of them when quite yellow deprives the Vines of nothing but insects, and that is a great deal. Complaints of the presence of mealy bug on Vines, and in bunches of Grapes, have been so numerous during the past two or three months, that decisive action is imperative for the extirpation of the scourge; and in no other way can this be so effectually accomplished as in the simple manner indicated.

A week or ten days after the fading leaves are removed the Vines will be ready for pruning. Possibly a little moisture may exude from the "cuts," but no alarm need be felt on that score. It will only amount to mere dampness, for it will be a wonder if a drop forms and falls, and if it did there would be nothing to fear, for the "loss" would be infinitesimal, as it would consist of water, nothing but water. Immeasurably greater harm is done to Vines by deferring the pruning too long, then by completing it too soon after the leaves fall, or are removed when withered as suggested.

After pruning comes the work of cleansing the Vines, the plants, and the house, for it is of small use doing one without the other. Each plant should be examined carefully, and if there is a suspicion of insects, should be laid on its side and drenched—syringed over and over again with an insecticide. It does not much matter which or what, provided it is forced through the syringe at a temperature of 120°. If insects remain alive after the application, it will be

the fault of the operator, and proof that the work has not been well done. But the syringing is not all that may be required, for the soil often contains many insects, especially when through careless watering it is half of the time too dry; the drainage may then be full of them and the roots encrusted. In that case the best plan is to destroy the plants, the next best plan to stand the pots over their rims in water for twenty-four hours. No doubt the plants may then have more water than is good for them; but when it is a question of too many insects or too much water, the latter is certainly the lesser of the two evils, therefore the one to be best endured.

In endeavours to banish insects from vineries, and especially the woolly coccus, it is questionable if half sufficient attention is paid to the soil, particularly dry soil, in pots and borders. That is their place of refuge, their nursery, their natural hybernating medium, from which they emerge in due time, and pursue their career of devastation. Space, however, is at present exhausted, though the subject is not, and may possibly be resumed another day.

PLUMIERIAS.

As the culture of Plumierias has not been described in the Journal, we applied to a gardener who had grown and flowered these plants to favour us with a few hints on their management. His reply is as follows:—

Having had during the last four or five years plants of the above under my charge, I was pleased to see the beautiful illustration and accompanying remarks in a recent issue of the Journal, and as requested readily describe the mode of culture pursued by me. In Miss North's museum at Kew I recollect noticing a painting of *P. rubra*, at least my impression is that it was *rubra*, and in a description of it there are some interesting remarks, if my memory serves me right, to the effect that at a certain stage of the flowering season in its native home a large caterpillar appears and devours the flower, and in the painting referred to is represented as creeping towards it. To lovers of sweet-scented flowers this plant will be appreciated, as the perfume is delicious. I have found that a stove temperature is necessary to grow and flower it satisfactorily, then if proper attention is afforded as regards watering and compost, not much difficulty may be experienced in its management. Good turfy loam three parts, with one of well-decomposed manure, a dash of silver sand, and a few pieces of charcoal suits its admirably. After the flowering season, which generally occurs during August and September, and when the foliage commences turning yellow, water should be gradually withheld, and when the whole of the leaves have left the plant may be withheld altogether for some weeks, care being taken that the plants are out of the way of drip, as during the cold season if kept too moist, they are almost certain to decay at the soil level, and if decay once sets in it is no easy matter to arrest it, on account of the fleshy nature of the stems. In early spring, or when signs of growth appear, the plants should be shaken out, removing a portion of the old soil after the manner of shaking out *Fuchsias*, and indeed a compost that will grow *Fuchsias* will suit *Plumierias*. Water should be applied with much caution for some weeks until the roots have taken well to the new soil; the supply may then be increased, and when in full and vigorous growth occasional applications of soot water will be of much benefit. The plants should be shaded from bright sun, and it is essential to use the syringe very freely, as aphids, thrips, scale, and mealy bug all seem to be much enamoured of the succulent nature of these plants, and must be guarded against accordingly, or the handsome green leaves will soon be bereft of their beauty, and the chances of the plants flowering freely be very remote.

To propagate, I have found it best to stand the stems erect by the aid of a small stick on the surface of sandy soil or cocoa-nut refuse, and not insert the cuttings, as they are very apt to damp if the latter method is adopted. The striking material should be moderately dry.

PLANTING FRUIT TREES.

If possible secure your trees from your own district, provided you can get them healthy and true to name. If you know a healthy properly trained tree when you see it go to the nursery and select for yourself, but if inexperienced in the matter get a practical gardener to select for you; but send early, or all the best trees may be gone. Trained trees for walls should be properly balanced with not only an equal number of shoots on each side, but

as nearly the same strength as possible. Look well to the bottom branches—they should be stronger than the upper ones—a desideratum rarely secured in nursery-trained trees. The fact is, too much is attempted in one season, for if nurserymen would be content to establish three good shoots instead, as is often the case, nine or eleven, it would be better for the future of the tree. It is impossible to establish the bottom branches of a trained tree unless it is done before the upper ones are formed, hence the importance of giving them at least one year's start. This principle also holds good for pyramids. The tendency of sap is upwards, therefore to divert it from that course some strong attraction must be provided from the beginning, and this we can only secure by establishing fewer branches the first year.

The trees must not be out of the soil longer than is absolutely necessary; therefore prepare the sites for them before they come, so that there may be as little delay as possible. Let the tips of every root of any size be cut off clean with a sharp knife, and if any of the strong roots be bruised, or in any way damaged, cut them clean off behind the injured parts; they will then throw out numerous small roots such as will be of real worth to the tree. On lifting a *Glou Morceau* Pear the other day which had never been satisfactory, we found it had been planted without pruning the mutilated roots, and consequently they had neither healed nor thrown out fibrous roots, but were covered with numerous knotty swellings resembling club-rooted Cabbage. It may not be necessary to tell some people not to plant too deeply—no deeper than the trees were in the nursery; but, alas! everybody does not know it, and until they do there can be harm in reiterating so simple and important a truth. I called upon a farmer friend a few days since, who, I found, had just purchased some standard Plum trees for planting in one of his fields. His man has just planted one, which I found he had done in much the same way as he would a straining-post for a wire fence, with this exception, that a hole 6 inches deep was left to be filled up with manure.

To plant deeply in any soil is to court failure, but to plant deeply into a strong clay such as the above was, is to especially provide for complete failure, as you simply plant your tree in a hole that will be full of water half the year, and that will soon make short work of your trees. In such heavy soils far better results would follow from fetching a load of soil and planting on the surface, provided they were well staked and mulched with littery manure.

Plant, if possible, when the soil is moderately dry, and on no account do so if it be very wet, as that alone is sufficient on heavy soils to render your prospects abortive. After carefully spreading the roots out straight, scatter the finest soil over them, not burying all the roots in one layer, but in several layers, with a covering of soil between each, and after covering the top layer about 3 inches, well tread it down and level the surface. All, with the exception of wall trees, should be well staked when planted, and a mulching of half-rotten manure will benefit trees of all forms.—J. H. W.

ABUTILONS.

Those who can afford space to grow some of these plants either to cover a wall or trained under the roof of a greenhouse or conservatory I would advise them to try planting out. Given a suitable soil and rooting space, with an intermediate temperature, they grow very fast and soon cover a large space. When rightly managed they are for the most part of the year in flower, but if wanted for winter flowering, for which they are very suitable, a more limited rooting space will be found to answer best. When established the difference must be made up to the plants by plentiful waterings and judicious feeding. Thinning the wood when too thick and training the remaining shoots improve the plants by preventing uneven or coarse growth, so detrimental to the other parts of the plants. I admire them in pots when well grown, as they flower freely, and I grow a good number in that way; but although useful and ornamental they do not afford sufficient flowers for cutting, whereas those planted out give them by hundreds.

Our conservatory here joins the house, and is 45 feet high and the same in width between the wall of the house and the hot-water pipes, which are arranged below the floor of the building. There is a border 4 feet wide and the same in depth, running nearly the whole width of the house. In this border is planted one plant of *Abutilon* *Boule de Neige*, one of *A. Thomsoni*, and one of *Canary Yellow*. The first-named plant has quite outdistanced the others and covers the whole space, is perfectly healthy and flowering abundantly. The plant flowered equally well last winter. The foliage of *A. Thomsoni* being variegated, is a pleasing contrast to the dark green of the other one. Last week my employer counted flowers up to 2000 and left hundreds more.

I will state briefly how the plant has been treated, our object

being to flower it during the principal autumn and winter months. During June and July the plant is allowed to run rough, and is kept rather dry at the roots, but not sufficient to do harm to the wood and foliage, affording plenty of air night and day in order to ripen the wood and give the plant a rest. About the beginning of August the necessary pruning is done by cutting out many of the gross shoots, thinning others where too thick, and laying in sufficient to well furnish the wall. Then a few inches of the surface soil of the border is removed and replaced by a mixture of two-thirds loam and the other leaf soil, and made very firm. Then a thorough soaking of water is given at two or three different times to make sure the whole is well moistened. The plant soon starts into growth, and in a short time produces flowers, which it will continue to do more or less the whole winter. As all the Abutilons make roots freely when in a confined space they soon ramble through the whole mass of soil; therefore weak manure water should be applied once a week, and other waterings as often as required, in order to keep up the vigour of the plant.

The flowers, when cut, are arranged in shallow vases with sprays of *Asparagus plumosus* intermixed, and they have a very pretty effect. Green fly is liable to attack the young growth, and to prevent that as much as possible, I syringe the plant heavily occasionally with clear water from the garden engine, the small syringe is not powerful enough to dislodge them; no fumigating being allowed in the conservatory.—THOMAS RECORD.

THE FRUIT ROOM.

It is certainly much to be regretted that although most structures intended for horticultural purposes have received their full share of attention, and the most approved modes of erecting them have been at times ably discussed in this Journal and other gardening works, the fruit-room has scarcely ever received a passing notice. Assuredly this cannot arise from the indifference with which it is regarded, for it is of the utmost possible importance; but somehow fruit-rooms, generally so called, form such uninviting features in most gardens that they are never visited by fashionable company. That this should be the case is unfortunate, for a good collection of Apples and Pears in the month of November is as well worth inspecting as anything the plant houses contain at that time; but when a makeshift of a shed, or some hovel of no longer any other use, has to be put in requisition for the purpose of keeping fruits, those having the management of it naturally shrink from inviting anyone to see their collection when huddled together in such humble quarters. They nevertheless manage now and then to keep their fruit pretty well in such houses or sheds, and not unfrequently better than is sometimes done in structures of greater pretensions, and we are, therefore, led to inquire if there is not something wrong with the latter, and a careful investigation into the matter confirms the suspicion that this is really the case. The subject of keeping winter fruit being so important, let us examine the elements which either lead to success or the contrary.

When we look into the mode which Nature adopts to insure the reproduction of each species, we find that all seed-vessels or receptacles have a function to perform, and when this is accomplished they perish. Some seeds are scattered abroad by the bursting of the seed pod, and by a jerk thrown some distance. Others are clothed with down, and dispersed far and wide by the wind. Others depend on their removal being effected either by birds, animals, or some similar agency, and of such, perhaps, the Apple and Pear may be accounted examples, while they also exhibit the seed enclosed in a fleshy substance capable of resisting decay for a greater or less period—in the wild ones, certainly until the proper time for depositing the seed in the ground; and assuming the fruit to fall where it is grown, the conditions for its keeping are prepared for it by natural means. Dead leaves and herbage form a sort of nest as well as a covering, securing the preservation of the seeds until the appropriate time for their being deposited in the earth. Our object, however, is the preservation of the fruit, and the seed is no further regarded than as being a component part of the fruit; but as Nature has shown us that a cool and far-from-dry medium serves all the purposes of keeping the fruits spoken of through the inclement part of the winter, we may not be far wrong in copying to a certain extent some of the conditions thus laid down.

It being shown that a cold medium is the best to prevent decay in the fruit now under consideration, the question arises, How is a cool atmosphere to be obtained? To a certain extent we have but little control over the temperature, for though we might increase that of the atmosphere of the room, we cannot easily diminish it; but something may be done in the latter way, or, at all events, the evils of overheating our fruit-rooms may be avoided.

To crowd a house with Apples and Pears in the warm weather of the early part of September is making it little better than a pest house, especially if there be very little ventilation; for the quantity of fruit lying in so confined a space engenders heat, or, what is equally bad, vapours are given out that are anything but favourable to the preservation of the fruit. Yet how common it is to crowd the fruit-room so early in the season. Apples keep falling, and birds and wasps attack the Pears, and, consequently, there appears to be no alternative but covering the shelves with fruit, perhaps three or four thick. Ripening takes place with more or less rapidity in consequence of the forcing to which the fruit is subjected, the close stifled state of the room, and the warm condition of the external air hurrying on the ripening.

Assuming, therefore, the position in which Nature often deposits her fruits to be on the whole favourable to their keeping (and we often see that an Apple which has fallen softly amongst long grass or other herbage exhibits as high a state of preservation when found there in winter as others of its kind when housed in the ordinary way), we are led to consider that plenty of fresh air is by no means unfavourable to the keeping of such fruits. On this account, therefore, our fruit-rooms ought to be well ventilated, and they ought not to be too low, or if from circumstances they must be so, they should be ventilated at the top as well as at the sides and ends. The best form for a fruit-room when it stands alone is an ordinary span-roof, laid on dry—that is, not embedded in mortar in the usual way; below the rafters the roof may be ceiled halfway up following the inclination of the rafters, with a flat space of some 3 or 4 feet in the centre, in which a latticed ventilator may be fixed, the latticework very open, and extending the whole length of the room. There should be a sort of contrivance for closing the latticework—a board, say on hinges, like a long trap-door. This is better than sliding latticework, as the latter is apt to get out of order, and is not easily moved. The tiles, being open, will allow all vapours that find their way into the apex of the roof to pass through, and the ventilator will only require closing in severe weather. In dry situations it would also answer as well to have the house partly under ground, say 3 feet or so; this tends to keep the temperature more equal, and in the hot dry weather of the dog-days is certainly a relief from the heated air outside. The side and end ventilators may be of glass, not allowing, however, any windows to the south, and for the same reason it would be better if the building were shaded from the mid-day sun in that direction, buildings being better for that purpose than trees. The situation ought also to be unconfined, and free from all noxious vapours and damp exhalations. The internal fittings might be in the usual way, a series of shelves all round, and a table shelf in the centre, and if the latter had drawers in it so much the better. The shelves ought not to be too close above each other—four or five in a tier is quite plenty—the highest one being at least 7 feet from the ground. It is customary to make the shelves partially open, but I am not certain that this is required. One of the best-keeping fruit-rooms I ever had to deal with had slate shelves, close and impervious. Care, however, was required not to allow the fruit to tumble about on a shelf so hard. I am no advocate for straw, or anything of that kind, under the fruit.

There are many conditions in which fruit has been kept tolerably well, and for a long period. A cool cellar is not by any means a bad place, only the quantity ought not to be large, or ventilation must be obtained; but the currents of fresh air that are wanted in September may in a great measure be dispensed with in December, or, at all events, much less will do. A cellar is better than a great many fruit-rooms. I have also retarded some fruit in an ice-house and kept it later there than it would have kept in another place, but the propriety of retarding fruits, excepting for special purposes, is much questioned; certainly the flavour is deteriorated. I have also seen a quantity of Apples buried in the ground like Potatoes. This was merely for an experiment, and the result was that many of them burst, much the same as a Potato will when boiled with the peel on. Keeping them in a chalk-pit or cave approaches so much to the cellar that it may be classed as the same. Sheds of all kinds are used to store Apples in most places where they are grown abundantly, and in Kent thousands of bushels are kept in heaps on the floor of the hop-drying kilns, which, being lofty and airy, are by no means bad places. The great misfortune is, the fruit often laid in heaps from 2 to 3 feet thick, and a little straw thrown over it in severe weather. Keeping Apples in air-tight boxes or jars has been abandoned of late years, and casks of various kinds are occasionally used, but more frequently for transporting fruit than for storing it away. Although Apples will occasionally keep a long time under conditions different from those now given, it is not to be inferred that these methods are better, as the fruit might, perhaps, have kept a little longer if fairly tried in the way described.

Before closing these remarks I may observe, that as fruit

ripens earlier in certain seasons than in others, and in some is charged more abundantly with those juices which promote decay, the keeping is not always alike, even when attempted in the same way. A well-perfected fruit may be as forward one season by the 1st of September, as it will be in another by the end of the same month; while it is almost needless to observe that the ripening, and, consequently, decaying influence of a warm month like September tells more than an equal length of time later in the year. It is not too much to say, that the thirty days in September ought to be accounted equal to the fifty days that next follow, taking, of course, average seasons. Hence, fruit that ripens so much earlier than usual has but a poor chance of keeping well if the weather be warm. Those, therefore, that want to prolong the season of any particular fruit must keep it as cool as they can, and success will be in accordance with the reduced temperature, all other conditions being favourable. In a general way, the place most conducive to the good-keeping of fruit is similar to that which preserves milk—one with a cool atmosphere and abundant ventilation, and free from all vapour, bad smells, and stagnant air of all kinds. In fact, a fruit-room ought to be as sweet as a dairy.—J. O.

PLANTING AND TRANSPLANTING.

GENERALLY speaking the removal and planting of trees and shrubs is an operation to be performed in the months of September, October, and November, according to orthodox rules. But, then, as regards myself, I happen to be one of those self-willed individuals who follow no conventional rules in connection with garden operations, and as gardening is a matter of business with me the fraternity will probably stigmatise me as perverse and headstrong. Be that as it may, whenever I find it desirable or necessary to remove and transplant trees or shrubs, and I have a convenient opportunity, I put aside all considerations as to the time of year, and submit only to the negative dictates of frost and much wet. I have transplanted trees and shrubs in the middle of summer and in the middle of winter, in spring and in autumn, the after-treatment, of course, being influenced by the weather, and never have I found that the success or failure of the operation could be directly or indirectly traced to the mere season of the year at which it happened to be performed.

This assertion may be diametrically opposed to the opinions of many of the most able and experienced gardeners. I nevertheless adhere to it, and even deny that the best time to remove trees is when there is plenty of moisture in the ground; in other words, when there is sufficient moisture in the soil to cause it to hold together in solid spits. I like it best when it will crumble and run in among the fibres and roots, and this I find it will do best in the summer time, when the ground is comparatively dry. Much, I am aware, depends on the nature of the soil, and if it is naturally crumbly and light probably the best time to plant trees in it is the autumn or winter; but even this I will not venture positively to assert, for I have invariably found that, no matter what the soil is, newly planted trees are likely to do best when the roots start into action immediately after planting. This is certainly not done in the winter unless the season happen to be unusually mild; and although the trees may sustain no injury from remaining a long time inactive it does not disprove what I affirm.

Some years ago I assisted in removing a number of evergreen shrubs from one garden to another: they were taken two or three at a time on wheelbarrows to a distance of about half a mile, and the weather was both hot and dry, the period of the year being about midsummer. As each was planted a basin was formed around it, the soil being in a crumbly state. This basin was filled up twice with water, which seemed to run the soil in amongst the roots, and leave them as though they had never been removed. They took to the soil immediately, and I never knew fresh-planted shrubs do better. I thought at the time that it was incurring too great a risk, as the shrubs were fine specimens; but the result proved that all my fears were groundless, and if since then I have had occasion to remove trees or shrubs at any period of the year I have never hesitated to do so. The weather subsequent to the operation will suggest such precautions as are necessary to insure safety—that is, in the way of shading, syringing, mulching, or watering, and staking in case of high winds. These precautions are often necessary, and the neglect of them is more frequently the cause of failure than the supposed wrong time of the year.

I would not, however, have it understood that I am advocating summer planting in preference to autumn or winter planting. There are cases in which it would be entirely out of the question to perform such operations in the summer on account of the pressure of other work; nor does what I assert affect this matter in the least. What I would recommend is not to be bound by usage, nor to be led by would-be clever theorists, who describe

minutely how the tree should be taken up, how the hole should be dug, how the soil should be trodden over the roots, the month, the week, or even the day on which transplantation should be performed, and such matters of detail as are far better left to the discretion of the operator.

Many gentlemen lay out large sums of money in the purchase of trees and shrubs, and make extraordinary mistakes in the planting and disposition of them, simply, it appears to me, for want of a few practical lessons, and partly, perhaps, from being unacquainted with the nature of the trees which they plant, or their knowledge being confined to the simple fact that trees should be planted with their roots downwards. This is rather a limited knowledge of vegetation; but judging from the manner in which many trees are planted one would think that it was also the extent of the knowledge possessed by the planter. For instance: a gentleman owns a field or paddock, and desires to have a belt of trees round it. He goes or sends to a nursery for one or two hundred young forest trees, and they are planted, the turf being replaced close around their stems. While the owner is congratulating himself on the pleasure he will experience in soon having a plantation of vigorous young trees, some of them are dying, and the rest do not grow. How is this? The nurseryman who supplied them is blamed; it must be his fault in supplying bad trees. What else can be the reason? Trees are pointed out as growing vigorously in neighbouring fields, with the grass extending up to their trunks, just as he would like his own to be, and he cannot see why they should not. Now, I would simply inform him that the grass growing under an old-established tree is merely there on sufferance, the tree has the mastery, and will not allow the grass to attain more than a certain degree of strength; but with fresh-planted trees the case is different, the grass pushes out fibres long before the tree, and the roots are down among those of the tree before the latter have made a single fibre. In fact, the grass abstracts all the moisture from the ground at the time of the year when the tree requires it most, so that the latter is left to starve, consequently it does not grow. The gentleman, however, cannot see this, and blames the nurseryman; but if he will take a useful hint, and look nearer home, he will find the remedy. When the trees are planted let the ground be kept bare of herbage as far as the roots extend, and this until the trees are thoroughly established.

In another case the trees are planted in gravel or sand, and in this they cannot grow for want of nutriment. The nurseryman cannot very well be blamed in this case, for the cause of failure is obvious, and the want of success is at once attributed to it. In consequence of this discovery the owner orders the surface of sand or gravel to be removed, and two spadefuls of strong manure to be placed close to the stem of each tree; or he orders each to have half a pailful of good strong liquid manure; so they are poisoned, and eventually succumb to their fate. Possibly the gentleman employs a gardener who well knows that liquid manure beyond a certain strength will injure, perhaps kill, his Cabbages, and he will possibly suggest that the stuff might be a little too strong. Well, then, the gentleman will buy more trees, and treat them to liquid manure in a weaker state; but even then somehow or other they do not grow. Now, I would suggest that newly planted trees have neither the mouth to imbibe or the stomach to digest liquid or even solid manure, and that trees require plain soil to fibre into: consequently if a good-sized hole had been made in the gravel for each tree, this filled up with common soil, and the trees planted in it, they would probably have done well, and when established pushed their roots into the gravel and derived a certain portion of nourishment from it.

It must not be supposed that I have merely pictured imaginary possibilities; for I have seen instances of what I have described, and have known gentlemen purchase valuable shrubs and trees to plant on their lawns; but, as a rule, the practice has been to lay the turf close up the stems after planting. Two-thirds of those which I have known treated in this way have either died or barely existed, and this I can ascribe to no more likely cause than replacing the turf over the roots. I have frequently taken off the turf round coniferous and other trees, removed some of the soil, and have noticed that in almost every instance, except after continued rains, the ground has been hard, dry, and seemingly impervious to any amount of rain. It is evident that such are not the conditions in which a tree could be expected to grow and flourish; it is worth while, therefore, to take a lesson from the fact, and in planting trees, especially those which are valuable, to leave the surface of the soil bare for a certain space round the stems when they are planted on lawns. Let a neat circle be cut in the turf, and the appearance will be quite as good as if the turf had been laid close to the stems. This will go far towards insuring the safety of the trees both by permitting rain and artificial waterings to sink down, and saving the trees from the drying and exhausting influence of the grass, which takes up the moisture for its own support.

There are other circumstances in connection with planting trees and shrubs which it would be worth while to notice, for it is astonishing how little attention is given to the subject by a large number of gardeners, young ones in particular, who apparently consider it a matter scarcely deserving more than a passing thought. Numbers of trees are thrust into the soil with torn or bruised roots; others are buried much deeper than they ought to be; many have the soil thrown in solid lumps on the roots, this being often trampled and trodden until it becomes as hard and solid as it is possible to make it, as though planting a tree were an operation differing in no respect from setting up a post or scaffold pole. Then, again, fresh-planted trees are left all the winter to sway and twist about with the force of the wind, which alone would prevent the roots taking hold of the soil. These and other shortcomings are not at all uncommon, and appear to result from a thoughtlessness that in effect is as culpable as wilful carelessness or neglect. The old axiom, that "what is worth doing at all, is worth doing well," applies in all its force to planting trees; for it is by no means pleasing to the owner nor creditable to the operator when, after planting a number of trees or shrubs, a large per-centage of them die, leaving ugly gaps, which must be, and are, eyesores to all who behold them. The neglect of such precautions as are necessary to insure success cannot be excused on the score of taking up too much time; for to plant a tree well, and as it should be, does not take a minute longer than to plant carelessly. There are, it is true, causes of trees dying which are not always under the control of the planter, and for which a certain allowance ought to be made; but, then, it is undeniable that careless planting is productive of more failures than any other cause that I am aware of, and this must be my apology for offering these remarks.

What I have said refers more particularly to that class of gardeners who have no under gardener or other assistance, and many of them perform such work as planting in a manner far from creditable to themselves or the vocation which they assume to represent. It is not too much to assert that nothing can be of more consequence, as a rule, than the success or failure of fresh-planted trees, since they are ever before the eye, and afford abundant food for criticism. The character of the planter is, consequently, involved, and it would be well for him to give his attention a little, or, rather, much, to the art of planting, and not be contented simply with relying upon the facts that a hole must be dug, the root of the tree placed in it, and the soil returned and trodden over. Any labourer knows that much, and can do as much; and if the gardener desires, as he should, to receive credit for a little more understanding, he must show it in the way he performs his work.—C. F.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 13TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters in the chair; Mr. Pascoe, Mr. W. G. Smith, Mr. Michael, Professor Boulger, Professor A. Church, Professor Scott, and Rev. J. Henslow, Hon. Sec.

Potato Reversion.—Mr. Smith mentioned that eighteen years ago Mr. Fenn crossed two long sorts of kidney Potatoes—viz., the Early Coldstream and the Early Ashleaf, the result being tubers of a globular form, which he called W. G. Smith. After eighteen years, during which this had come true, one plant suddenly reverted to the original type, being 5½ inches long, the round tuber being only about 2½ inches in diameter.

Ivy Blossoms Malformed.—Dr. Masters exhibited specimens and drawings of a very unusual condition of Ivy, in which the "disc" on the summit of the ovary had become hypertrophied into a thick ring, the style occupying the depression in the centre, the border of the ring supported about ten anthers, all being supernumerary, as the normal number was present at the outside of the base of the ring. The specimens were sent by Mr. Archer Briggs.

Oak Timber Defective.—Dr. Masters exhibited specimens of Oak wood, which was used for spokes of wheels, which was found to break off short. It was referred to Professor Marshall Ward for examination and report.

Pinus Lambertiana.—Dr. Masters exhibited a branch of this species, received from Mr. C. Herrin of Dropmore, Maidenhead, with two cones about 1 foot long. The size when growing naturally in California is said to be double that of the present specimen.

Cleistogamous Lawn Plants.—Mr. Henslow showed specimens of several species of plants which are propagated by cleistogamous flower buds. By that means, while retaining a dwarf habit, they are able to multiply very rapidly, and to extend over considerable areas in a tennis lawn. Although none of them are perennials, they remain so reduced in size that they are not exterminated by the mowing machine periodically cutting them down. The result is that each species has more or less completely covered certain patches of ground to the almost entire exclusion of everything else. The plants in question are *Cerastium glomeratum*, *Montia fontana*, *Trifolium prorepens*, *Sagina procumbens*, *Alchemilla arvensis*, *Veronica arvensis*, and *Poa annua*. Mr. Henslow added that he had observed many years ago a *Trifolium* flourishing in

the same way on the close-cut grass in Kew Gardens, on the site of the present rockery.

Rumex crispus gymnomonacicus.—Mr. Henslow exhibited specimens of this plant, which bears hermaphrodite flowers on longer, with female flowers on shorter pedicels, thereby forming whorls along the main peduncle. It does not appear to have been described in any work as being in this condition.

Cotyledon umbilicus, abnormal.—Mr. Henslow exhibited a specimen and leaves of this plant, found growing in a wall at St. Ives, Cornwall, the peculiarity being that it bore a flat, expanded, rosulate arrangement of leaves exactly like the House Leek, *Echeveria*, or several sorts of Saxifrage. The leaves were spatulate and not peltate at all. Some few growing freely were funnel-shaped.

Raspberry and Blackberry Hybrid.—Mr. Henslow drew attention to the foliage of a supposed hybrid received from Mr. Viecars Collyer of Leicester. The plant blossomed, but bore no fruit this season. The flowers were exactly like that of the Raspberry, as well as the tomentose under surface of the leaves; but the method of forming the quinate leaf out of the ternate agreed with that of the Blackberry as follows:—The simplest form of leaf is a single oval leaflet near the flowers. This becomes lobed at the base, and so two leaflets are given off, forming the ternate leaf. From the basal pair in the case of the Blackberry two more are given off, and thus form a quinate leaf, the lower four leaflets being nearly "palmate." In the Raspberry, however, the second pair of leaflets are given off from the terminal leaflet, just as were the primary pair. Consequently the five leaflets now form a more decidedly pinnate leaf. In the hybrid in question, although in all other features it agrees with the Raspberry, yet in this one in particular it resembles the Blackberry. As no fruit was produced a comparison could not be made with them.

ROSE HOUSES.

YOUR correspondent, "S. S.," recently called attention to an article in which I said, "If the house was constructed specially for the production of blooms for market it would be much lower;" that is, lower than 8 or 9 feet from the floor to the ridge. I intended to have written 9 or 10 feet, but that does not matter materially. I noticed the slight error I had made after the figures appeared, but did not think it necessary to make any correction. I think it will have been understood that I do not advise an arched trellis on which to train the plants when the flowers are grown entirely for market purposes. My reasons for this are several, but the main one only need be mentioned. I advised the bush method of culture, and for the simple reason that I am of opinion that finer flowers are produced than when the plants are trained on a trellis. The difference between the two is quantity on the one principle and quality by the other, although the system of pruning will influence this matter in no small degree.

I must, however, return to the question submitted by your correspondent. I do not know if "S. S." will accept a foot lower from the lowest figure given as "much lower" or not. This is a matter, however, in which the cultivator must be guided to a very large extent indeed by the ground on which he proposes to build, or more particularly by the natural soil. If the soil rested on a subsoil that would insure perfect drainage, such as sandstone, gravel, or anything of a similar nature, and the soil was of a suitable nature in which to grow Roses, or could be rendered so without much trouble, I should build the house 7 feet high from the doorstep to the ridge (inside). I should try to arrange the doorstep to be about 2 inches above the ground level—not more if I could help it; in fact the step, of whatever it might be composed, would be arranged on the footing of the outer walls. The best way of arriving at this matter is to suppose I was building a house for Niphetois blooms for market. It would be 100 feet long (or as near that as I could make it) to work in squares of a certain size—namely 18 inches by 1 foot, the former being the distance the rafters are apart. The width of the house would be 18 feet, the side walls would be 2 feet 6 inches high, the glass 1 foot 6 inches, making the house 4 foot high at the eaves. Your correspondent will say surely this is a flat house, and so it is, but I am not called upon to discuss reasons for advocating a flat-roofed structure in preference to one with a sharp pitch, such as are built nowadays. Some day I may have something to say on this matter.

I have given the height, length, and width of the structure; it is now necessary to divide it. The side beds would be 2 feet 6 inches each, the paths the same size, and the centre bed 8 feet. That would take up the whole space calculating the house to be 18 feet inside measurement. Your correspondent may ask, Am I to stoop when going round this house to do the necessary work and gather the blooms, &c.? Well, that depends upon the height of your correspondent; it would nearly accommodate me without a hat, but instead of being 5 feet 4 inches from the centre of the walk to the glass or thereabouts, I propose making it a foot higher by lowering the walks that depth. The house would then afford room enough for all ordinary men. I have a double object in this—First, one of economy, because I could dig out the walks

at a less cost than I could build the structure 1 foot higher; and secondly, if the soil was of a suitable nature for Roses it would be placed in the central and side beds. This would prove a saving of labour, and require considerably less soil to make up the beds. The internal walls for the central and side beds would not be 2 feet 6 inches, the same as the outer ones; they would not exceed 18 inches, which would allow head room for the plants. If I was compelled to have the walks of the house practically on the ground level, or a very few inches below it, I should have the structure 8 feet high. Houses of the nature I am advising would not do well for private places where ladies might wish to go round them, but in growing specially for the market I should construct them on the principle that no one required to go through the houses but myself. I may add that the side glass would simply consist of squares of glass placed edge to edge, resting on the wall plate and supported against the eave. To keep them in position a small strip of wood would be secured to the wall plate, and the same on the under side of the wood to which the rafters are secured, as well as on the uprights from the wall plate to the eave, the squares being pressed against a little putty and tacked into position; no side ventilation would thus be provided according to the orthodox method, but the squares could readily be removed if deemed necessary.—WM. BARDNEY.

CLOVELLY COURT, BIDEFORD.

A DESCRIPTION of Clovelly Court would be incomplete without a reference being made to the picturesque village from which it takes its name. Leaving Ilfracombe at ten o'clock in the morning by the well-fitted Velindra steamer, the visitor, passing Lundy Island half-way on the right hand side, will find himself two hours later within 200 yards of the rough boulder-constructed pier of Clovelly, whither he and his companions are rowed in boats of the sturdy fishermen. The view of Clovelly from the sea, with its string of irregular white and partly lichen-covered cottages enconed on either side of the gigantic staircase-like street, with wooded slopes on each side, is strikingly beautiful. From the pier, which is reached at low water by means of perpendicular ladders, to that point at the top where the principal street, which is almost precipitous in some parts, joins with the high road, there is not 60 yards of level ground. The only piece of level is a kind of landing in the street-staircase, one-third of the way up, commanding a view of the harbour, with its red sailed fishing boats. Pretty cottages line the street, here two or three together, there standing apart, almost all with well-cared-for gardens, and at one point the village seems to end abruptly, till the visitor discovers that the road is carried through a tower-like house.

Clovelly Court, the North Devon residence of Miss Hamlyn Fane, is high among tufted trees, half a mile west of the village. It is a handsome mansion, erected in 1780. Close by stands the church, in which the late Canon Kingsley ministered for so many years to the spiritual requirements of the Clovellian population. The grounds are open to visitors by favour of the owners. They are extensive, of great beauty, and a variety of pleasing views present themselves at every turn in the winding paths, which, passing by lichen-covered rocks, and through leafy glens and ferny combs, suddenly opens upon the sea. The zigzag drive through the "Hobby" wood, though of great beauty, is, nevertheless, calculated to inspire the stoutest heart with a wholesome fear in ascending and descending, as it were, on the very edge of the precipitous rocky slopes some 400 feet above the sea. It skirts the cliff line for three miles, thereby affording grand glimpses of the sea on the one hand, and on the other of the woods, streams, and glens for which North Devon is celebrated. "Gallantry Bower" is the name given to a steep and lofty cliff overlooking a glorious panorama of sea on the one side and richly wooded country on the other. It is 360 feet above the sea, and less than one mile westward of the Court. A short distance from Gallantry Bower is Mouth Mill. It is a prettycombe, where two streams unite, opening to the sea. The view westward to Hartland Point is very striking. Eastward it stretches over Bideford Bay to Baggy Point. A couple of hundred yards to the right from the top of the village and on high ground to the left of the entrance gate to Clovelly grounds, stands the lighthouse. The Park, opposite the north-west front of the Court, consists of table land, the soil being a deep loam resting on a stratum of clay. It was once famous for its hawks. "A Clovelly hawk against all the world."

Nearly all trees do well in the park and grounds at Clovelly, except at a few points where they are exposed to the Atlantic breeze, notably all Conifers. In the West Wood there are several fine specimens of the Silver Fir nearly 100 feet high, and ranging in girth from 11 feet to 15 feet. Spanish Chestnuts having a circumference of stem of 10 feet at 3 feet from the ground, while two specimens of the common Horse Chestnut measure 16 feet 8 inches and 19 feet 3 inches respectively round the trunk at the same distance from the ground. The Hobby Wood contains fine examples of Beech, Oak, Chestnuts, &c. The timber in the hollow being out of the reach of the Atlantic spray is especially good, and the declivity from the drive alluded to above down to the beach is wood throughout. Flowering shrubs, especially Rhododendrons (which form a cover in the Wilderness), Escallonia maerantha, and Hydrangeas do remarkably well here. It is a notable fact that in a rather exposed part of the park north-west of the Court and extending to the terraced grounds southward of it there are several remarkable flat-headed bushes of Thorn of unduly large horizontal dimensions, remarkable by reason of the uniform flatness and height of head of all the bushes within the line of the Atlantic breeze, thereby

giving one the idea that a huge switching-hook had been passed with gigantic force simultaneously over their heads every spring and autumn. To this fact, the persistent restriction of top growth to a certain line, is to be attributed the unusually large spread of branches of the individual bushes, underneath and between which are to be seen a good number of the mottled deer scampering about, keeping time, as it were, to the music of the birds in the trees overhead.

All the glass houses, with the exception of the elegant conservatory adjoining the east end of the mansion and communicating with the interior and facing due south, are situate against south walls in the kitchen garden. They consist of three vineries, two Peach houses, one orchard house, one greenhouse, and one stove. Vines of Black Hamburgh, Golden Hamburgh, Muscat of Alexandria, Grizzly Frontignan, Alicante, and Venn's Black Muscat were all carrying heavy crops of medium-sized bunches of Grapes, which at the time of my visit gave promise of finishing well. Mr. David Atkins, the head gardener, finds Venn's Black Muscat Grape to set as freely as a Black Hamburgh does in a greenhouse temperature, and to colour as well as could be desired, thereby showing it to be a low-temperature Grape—that is, that it succeeds best in a cool dry atmospheric temperature while in flower and colouring. On the back wall of the late vinery there was a fine display of such excellent Roses as Niphetos, Bouquet d'Or, and Gloire de Dijon. Trees of Noblesse and Royal George Peaches, and Pine Apple, Pitmaston Orange, and Rivers' Orange Nectarines were in good condition and swelling good crops of clean healthy-looking fruit. I noticed that Mr. Atkins allows, as everybody ought to do, a good distance between the shoots of his Peach and Nectarine trees in training; from 4 to 6 inches is none too much, allowing for one shoot of the current year's growth being laid in between. There is no greater mistake in fruit culture, whether it be indoors or out, than crowding the branches and shoots proceeding therefrom.

In the stove I noticed good specimens of *Asparagus plumosus nanus*, Allamanda Hendersoni, in fine flower trained over back wall, against which are also trained flourishing plants of *Euphorbia jacquiniæflora*, growing in narrow border, *Euphorbia splendens*, *Clerodendrons Balfourianum* and *Thomsoni*, *Hibiscuses* (double and single flowered varieties), *Crotons*, &c. The greenhouse was gay with a variety of well-flowered plants usually met with in such structures at that time of the year. The conservatory alluded to above was remarkably bright with well-flowered plants of *Pelargoniums*, tuberous-rooted *Begonias* (double and single), among which were many promising seedlings, the flowers being large, well formed, and of pleasing if not new and distinct shades of colour; *Fuchsias*, including a grandly flowered plant of *Clapton Hero*, trained round a pillar 20 feet high in the centre of house. This is a good dark free flowering old variety, after the habit of the Old Carolina. *Abutilon Boule de Neige*, similarly trained, made a nice contrast. Tree and other Ferns judiciously intermixed with the flowering plants had a very good effect. A plant of *Dicksonia squarrosa*, having a stem 4 feet high and nearly a foot in diameter, supporting a good head of fine healthy fronds, gave a finishing touch to the central arrangement of the house, as also did some four or five dozen pots of the *Gladiolus*. The Bride, in grand flower, stood on the tessellated floor at the base of the front side stage, gave finish to an arrangement in that side of this beautiful house, which did Mr. Atkins credit.

A view of great extent and beauty is obtained from the conservatory terrace. Croyde, Morte Point, Baggy Point, and Braunton in the north-east, eastward thence is Westward Ho, and should the atmosphere be clear, Port Llyn, the nearest point in Wales; the opposite side of Bay of Bristol Channel may be seen thirty miles off, and half that distance in a north-westerly direction is Lundy Island, a place covering an area of 2000 acres of land, and almost encircled by iron-bound inaccessible cliffs, and interesting to geologists as affording "sections at the junction of the granite and slate." Out of doors hard by the conservatory I noticed a grandly flowered bush, 10 feet through of a pink-flowered *Veronica*, and in another part of the gardens a *Clematis Flammula* completely covered a house and tree close by, with its white sweetly scented flowers. Three hundred plants of *Chrysanthemums*, including the best varieties, are grown for the winter embellishment of the conservatory, &c. The kitchen garden is two acres in extent, the soil being a deep loam of good quality. It was well and judiciously cropped with vegetables of the most approved kinds and varieties. In conclusion, I may say that the general keep of the gardens and grounds attached to Clovelly Court reflect credit on Mr. Atkins, who has presided over them during the past twelve years, and that Bideford, eleven miles off, is the nearest railway station to Clovelly, Ilfracombe being twenty miles by road in a north-easterly direction.—H. W. WARD.

FORCING LILY OF THE VALLEY.

Your correspondent "M. M." seems to find forcing Lily of the Valley during the early winter months a decided failure, and some by reading his communication on page 418 may be deterred from attempting to have this much-valued flower as early as Christmas or the new year. In my opinion the difficulties are not nearly so great as "M. M." asserts. We find it comparatively easy in a house devoted to Melon growing during the season to have them in flower at Christmas, and even sooner. The crowns we obtain are English grown. They are procured as soon as practicable, and after being potted or boxed they are placed out of doors until required

to be taken indoors; they are then placed in an intermediate temperature, prior to being arranged in the forcing house, which, as I have stated, is a Melon house, and having bottom heat pipes for the beds. On the boards over the pipes we place narrow frames, which are nearly filled with cocoa-nut fibre, in which the pots are plunged up to the rim. Some loose moss is then shaken over the crowns, so that they are completely covered, and which is allowed to remain on them until the growths and flower spikes have pushed up through it. The frame is kept closed to this time, and the moss moist, when air is given and gradually increased until they are ready for being taken out of the frame, when they are placed on shelves well up to the light and slightly sprinkled with the syringe two or three times a day, which assists the development of foliage and flower spikes.

Our first plants last year were placed in heat on November 23rd, and there were some in flower on December 14th, and a few days before Christmas we had the whole finely flowered, many of the spikes having from ten to fourteen flowers of good size. We place about twelve or fourteen crowns in a 48-size pot, and the majority of them flower in the manner described. I think anyone having a house such as is used for Cucumber or Melon growing with bottom heat pipes may, if they procure good plump crowns, be able to have them in flower at the end of December or at the new year if they are treated in the way I have mentioned. Anyone not having suitable frames would find large boxes covered with glass quite as useful.—S. T. C.

HARDY PLANTS FOR CUTTING.

Will you kindly assist me with your advice as to what would be the best herbaceous plants for me to obtain now? I want those that would yield plenty of flowers for cutting purposes. They are used here largely for house decoration, and we require flowers with long stems, such as Michaelmas Daisies, Gladioli, and Delphiniums, Phloxes, or such like; the brighter and more striking the colours the better. I should be much obliged if you would name annuals for spring sowing of the same description. I have grown many different sorts, mostly shorter kinds. I want to make my list up of some more suitable for the purposes mentioned.—W. B., *Sussex*.

[The following are all good cutting plants and the colours safe to please most people. White flowers are always most sought after, and of these any, or the whole of the following, are suitable.

White Flowers.—*Achillea Ptarmica* fl.-pl., *Allium neapolitanum*, *Anemone Honorine Jobert*, *Galtonia candicans*, *Eupatorium fragrans*, *Campanula persicifolia alba* fl.-pl., *C. urticæfolia alba* fl.-pl., *Chrysanthemum Leucanthemum*, *C. maximum*, *C. scrobinum*, *C. Madame Desgranges*, *C. Mfs. Cullingford*, *C. La Vierge*, *Hesperis matronalis alba plena*, tall variety; *Iris florentina*, *I. germanica alba*, *Lilium candidum*, *L. longiflorum*, *L. speciosum album*, *Lychnis vespertina* fl.-pl., *Malva moschata alba*, *Narcissus incomparabilis*, *N. poeticus ornatus*, poeticus, and p. fl.-pl., best variety; *Phloxes Lady Napier*, *Miss Robertson*, and *Bridesmaid*, *Spiræa Aruncus*, *S. Ulmaria* fl.-pl., *Gladiolus Shakespeare* and *The Bride*, *Dahlias White Aster*, *Mr. Tait*, and *Henry Partick*, *Carnations White Clove*, *Gloire de Nancy*, *Comtesse de Paris*, *Comte de Chambord*, *The Bride*, *Virgo*, &c.; *Pinks Mrs. Sinkins*, *Mrs. Welsh*, white *Foxgloves*, *Convallaria polygonatum*.

Yellow Flowers.—*Achillea ægyptiaca*, *Adonis vernalis*, *Alstroemeria aurantiaca*, *Coreopsis lanceolata*, *Chrysanthemums Précoceité*, *Golden Fleece*, *George Wermig*, and *Mrs. Burrell*, *Doronicum austriacum*, *D. Pardalianches*, *Tulipa sylvestris*, *Gaillardia vars.*, *Harpalum rigidum*, *Helianthus pumilum*, *Helianthus multiflorus* fl.-pl., *Hemerocallis flava*, *Iris Pseudacorus*, *Narcissus* in great variety, *Lilium excelsum*, *L. croceum*, *Papaver nudicaule*, *Solidago canadensis* and *Shorti*; *Trollius asiaticus*, yellow *Dutch Tulips*, *Dahlias Mrs. Stancombe*, *Canary*, and *Mrs. Hawkins*, *Carnations Pride of Penshurst*, *R. H. Elliot*, *Mrs. Reynolds Hole*, &c., *Gladiolus Alsace*, *Lafayette*, and *Pactole*.

Those with red shades are *Carnations* in variety, *Gladiolus brechleyensis*, *Grand Rouge*, *Le Phare*, *Legouve*, *Flamboyant*, *Horace Vernet*, *Arabi Pasha*, *Montaigne*, and *Meyerbeer*, *Phlox coccinea*, *Dahlias Juarez*, *Comet*, *Chilwell Beauty*, *Glare of the Garden*, *Lilium tigrinum splendens*, *L. fl.-pl. umbellatum*, *Thunbergianum*, *Tritoma Uvaria*, *Papaver bracteatum*, *Schizostylis coccinea*, various *Tulips*, *Lychnis chalcedonica* fl.-pl., *Chrysanthemum Toreador*, *Roi des Précoces*, and *Salvia fulgens*.

Of blue flowers, which are not numerous, we have *Delphiniums*, easily raised from seed, *Agapanthus umbellatus*, *Salvia patens*, *Erigeron speciosus*, *Stenactis speciosa*, *Polemonium Richardsoni*, *Scabiosa caucasica*, *Eryngium amethystinum*, and *Geranium pratense* fl.-pl.

Flowers of rose and pink shades are *Anemone japonica*, *Achillea rosea*, *Dielytra spectabilis*, *Phlox Malame Mossent*,

M. Grahame, *Carnation Mary Morris*, *Princess Mathilde*, *Féodora Miss Joliffe*, and perhaps the pink *Malmaison*; *Gladiolus Eugène Souchet*, *Fra Diavolo*, *Teresita*, *Orphée*, *Phoenix*. Other necessary flowers are *Asters*, such as *turbinellus*, *elegans*, *Novæ Angliæ*, *Novi Belgii*, *Amellus bessarabicus*, *versicolor*, *ericoides*. All the *Pyrethrums* are suitable; *Gladiolus Lemoinei* and *André Chenier* are very fine; also *G. Penelope Amitié*, *M. Ad. Brongniart*, *Psyche*, *Hesperide*, *Diamant*, *Ne Plus Ultra*, and *Gandavensis* should be grown. *Monarda didyma*, *Convallaria Polygonatum*, *Foxgloves*, *Polygonum Sachalinense*, *Iris ruthenica* for foliage, *Spanish Iris*, also *German Iris*, any herbaceous *Pæonies*, and *Thalictrum minus*.

Good tall-growing annuals and biennials are white and purple *Sweet Sultan*, *Scabious*, *Salpiglossis*, *Branching Larkspur*, *Cornflower*, *Corn Marigold*, *Oenothera Lamarekiana*, *Quilled Asters*, white *Pæony Aster*, *Veitch's Miniature Sunflower*, single *Zinnias*, *Nicotiana affinis*, single *African Marigolds*, *Humea elegans*, *Gaillardias*, *Sweet Williams*, *Canterbury Bells*, and *Poppies* in great variety.]

CHRYSANTHEMUM PRINCESS OF WALES.

I AGREE with Mr. Molyneux's remarks, page 149, respecting the above variety, and I consider no stand of incurved blooms complete without it and Mrs. Heale. The beautiful form of these varieties when well grown claims a place in the middle row of any stand, and now we have *Violet Tomlin*, a purple rose-coloured sport from *Princess of Wales*, which (with the exception of *Refulgens*) I consider the brightest coloured of all the incurved. It requires the same good treatment as its parent. I hear, too, we are to have another one added to the family, a yellow sport from Mrs. Heale.

CHRYSANTHEMUM CONFERENCE.

I was much pleased to read the account of the Conference held at Sheffield on November 16th and 17th, and, like many other lovers of the "Autumn Queen," would like to have been present; but that in my case was impossible. I would now suggest that another Conference be held in the afternoon on the date of the National Chrysanthemum Society's annual dinner, if it could be so arranged, as then it would give members from a distance an opportunity of attending both the Conference and dinner. No paper is required in my opinion, but a further discussion on those read at Sheffield by Mr. Tunnington and Mr. Molyneux.—J. DOUGHTY, *Angley Park Gardens, Cranbrook*.

THE SEASON.

Now that the Chrysanthemum season is so far advanced it might be interesting to compare a few notes as to the success or failure we have met with this season. As far as my own observations are concerned, I have to report almost a complete failure, which has been brought about by damping, and which by report appears to be very general this season throughout the country. Those that appear to have suffered most are the large blooms, or more properly speaking, those that have been grown on the single-stem system for exhibition. But those that have been grown simply for decoration and cutting have escaped with very little loss. This damping I have no doubt has caused much anxiety, especially to those whose plants have been so full of promise, and the cause seems wrapped in mystery. As far as my own experience is concerned and the observations I have taken, I feel convinced that it is through the injudicious supply of water and over-feeding, especially after the buds have been taken, for it should be remembered that when the buds are swelling the plants do not require so much water as when they are in full growth, and I think if we were more careful in examining each plant and attending to its wants individually instead of pouring water and stimulants into it wholesale, it would be time well spent, and we should hear less of failures through damping. Of course the seasons must be taken into account, and there are times when damping is comparatively unknown to us, but the present season has been an exception. The growth of the plants has been everything that could possibly be desired, but with so little sunshine it has been next to impossible for them to ripen their wood thoroughly. Consequently the wood and foliage has been full of sap. Therefore, although the buds were at first so full of promise and held forth great expectations, the result is anything but satisfactory, and I would strongly advise all to be more careful in the supply of water and stimulants at the stage before mentioned. But some may say, "You cannot give Chrysanthemums too much" (and I have had it said to me too); but even if this should be the case in regard to plants growing naturally, I would draw attention to the fact that when plants are only carrying three or four blooms they cannot stand so much feeding, as there is not so much for the roots to support, and the grave consequence is the roots are surely poisoned, and when the time comes that we expect to see good returns for our labour, we see (and in some instances when only one or two florets have expanded) they begin to decay. Then we

are heard to exclaim, "What can be the cause? we cannot make it out," &c., and instead of it being a pleasure to look round them time after time, the sight of them becomes sickening, and through, I would conclude, the injudicious watering and overfeeding.—R. PAGE, *Stroud, Gloucester*.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the Floral Committee was held on Wednesday, the 21st inst., Mr. Sanderson in the chair. There were also present Messrs. R. Ballantine, Wm. Holmes, Geo. Stevens, Geo. S. Addison, W. Boyce, H. Cannell, C. Gibson, &c. A fair number of new Chrysanthemums were staged by Messrs. Cannell & Sons, Swanley, including Madame Baco, M. Tweedie, Yellow Lane, a bright yellow single, and others. A vote of thanks was awarded to Mr. Elliott of Jersey for a box of Jersey seedlings. Two very fine blooms of Mrs. F. Thompson were exhibited. This is an American variety which has proved to be synonymous with W. & G. Drover. The following first-class certificates were awarded:—

Miss M. A. Haggas (Messrs. Davis & Jones of Lilford Road, Camberwell).—A deep primrose yellow incurved sport from Mrs. Heale, of good substance and resembling the parent plant in every respect except colour.

Mrs. C. H. Wheeler (Mr. Thomas Butterworth, Benton Grange, Cheshunt).—A very large Japanese flower of a golden colour suffused with red and bronze similar to Edwin Molyneux, but having much broader florets.

L'Automne (Mr. Geo. S. Addison, Parchmore Road, Thornton Heath).—A soft salmon buff incurved flower with broad petals, and being of considerable depth and solidity is without doubt an acquisition to the incurved section.

Aleyon (Messrs. H. Cannell & Sons, Swanley).—A Japanese reflexed, broad, drooping florets, rose carmine, silver reverse, a deep flower of good substance.

EARLY CHRYSANTHEMUMS.

I HEARD it said a season or two ago of the early flowering sorts because some were not quite so prominent as before, "Ah, they are going back!" But it is not so, as this season has shown quite as much advance as can be expected, and more in some directions. The French raisers have certainly not done much with the early varieties, and if they send over such poor productions as they have this season they will soon be surpassed by the Americans, who can raise their own seed, and there are many amateur growers who are likely to obtain at least a few good sorts. I think I am justified in coming to this conclusion from the fact that two great steps in advance—viz., Grace Attick and Sam Henshaw, are both of American origin. Another distinct sign of progress is the marked advance in securing the seed of early sorts here in England. It is true the seedlings are only Pompons at present, but others I expect will be grown and seeded in due time.

As regards the shows of the early sorts of this season, we have had this difference, that no exhibitor at either one showed at the other. At the Crystal Palace Messrs. Davis & Jones were first with a fine group of well mixed varieties, showing besides, but not for competition, a very fine group of Madame Desgrange. I think it was the finest ever seen at a public show. I took the second prize for the group among which I had one poor plant of Grace Attick, the first plant, as far as I know, ever exhibited in England, and poor as it was, for it was overblown, it attracted more attention than any other. It is not much to my taste, but most people who have seen it seem to admire it; perhaps that is because it is such a very new type among the early sorts. Mr. Miles, of the Dyke Road, Brighton, took the third prize for a group of Mrs. Burrell and a few of other sorts to comply with the schedule.

At the show of the early varieties at the Aquarium by the National Society the most prominent exhibits were the tables of cut flowers, and their long expanse looked very beautiful. They were nearly all grown naturally without disbudding, but there was one thing that struck me in some of the exhibits—viz., that there were several sorts that ought not to find a place in a nursery or garden, for it is a waste of space and labour to grow the poor old sorts of a few years back. In this class Mr. Ware, of the Hale Farm Nurseries, Tottenham, was first with a fine representative collection, and Mr. Owen of Maidenhead second. Mr. Witty of Highgate Cemetery has first prize for a group without competition. The only new variety of any note at this Show was a fine group of what I should call a dark strain of the yellow variety of Madame Desgrange, named Mrs. Hawkins, exhibited by Messrs. Hawkins & Bennett, Twickenham. This was awarded a first class certificate, but I expect it will not turn out darker than other strains.

This season with its sharp frost at the very beginning of October has tested the merits of Alice Butcher, the red sport of Lyon, which proves to be one of the best for resisting frost when the flowers are expanded enough to show their colour. Lord Mayor, too, seems likely to be distinguished in this respect; 6° of frost did not spoil the flowers of Alice Butcher, which will, of course, increase its value as a variety for market and other purposes.

I regard the most prominent find of the season from a decorative point of view to be Sam Henshaw. It has been here, it seems, for a season or two, but like other American sorts attracted little attention because so many are almost worthless. It is said to be a seedling from Comte de Germiny and Viceroy of Egypt raised by Dr. Walcot of New York. It is a wonderfully strong plant, and grows about 4 feet high, having flowers 5 inches across. It begins to flower, at least did this late season, about the middle of October. The colour of the petals is a bright pale magenta inside, with a bright grey rather pink reverse. They are broad and long, incurving so much as to close over any eye

there may be in the flowers. It does not altogether please the critics, but is admired by the general public, and is certainly a marked addition to the October varieties; besides, I think, in good seasons it will give ripe and fertile seed in England.

Grace Attick is another American sent over a season or two back. It is said to have been raised by Mr. John Thorpe. It is quite a new departure, very dwarf, 2 feet high, Japanese, white in colour, with blooms from 4 to 5 inches across, the petals being of a long thin pipe-like structure. The habit is bushy with very spare foliage. It begins to flower at the end of July, but is of long-continued flowering habit, in fact its vitality seems largely centered in the production of flowers. I expect it to take a prominent place as an English seed parent. Its only defect seems a weak constitution, but this may be improved.

O. J. Quintus is a good variety from a semi-early decorative point of view. It is a robust and vigorous plant, growing 4½ feet high, with blooms 3 to 3½ inches across; Japanese in form, and a fine pink mauve in colour, well fit for after dark decoration. It is profuse when left to flower naturally. The petals stand straight out, which seems to enable it to stand wind and rain very well. It is of French origin.

M. Van Hulle is of continental origin, another fine robust useful plant, growing 3 feet high, with blooms 2½ inches across, very full of petals standing straight out; they are red flaked with yellow, borne on the plant in a way well suited for cutting purposes, as they come out altogether. This Pompon is well fitted for a small pot decorative plant, blooms in September and October, and comes into competition with Alice Butcher, but is stronger and better able to support itself than that. It requires little or no sticking.

Elsie is a good reflexed white October bloomer, ivory white, a robust plant, 4 to 5 feet high, flowers 3 inches across.

M. Délaux sent over seven sorts which were said to be early, but only one of them flowered before the end of October, that was Madame C. Souchet. It is a Japanese, 5 feet high, not bushy; the flowers are a deep magenta, 4 inches across, not unlike M. Chrétien; the other six were by no means in bloom by the end of October.

We have been particularly fortunate this season with our seedlings from seed grown here. I grew eighty-eight, and Mr. Ware of Tottenham about 200; he has two distinctly good and early, and five or six more fit to try again; they often come better the second season. I have one good one of last season and five of this, besides three or four to try again. Miss P. Broughton, English seedling from seed grown here the season before last, extremely white and elegant Pompon, flowers 2 to 2½ inches across, very stout bushy habit, 2 feet high, requires no sticks, a profuse bloomer, differing from all others. Flowers in September and October. Very useful for small cut flowers, and it makes a good small pot plant.

Clara White, Pompon, seed and plant grown here, dwarf, 2 feet high, flowers 2 inches across, borne on long stalks fit for cutting, stiff habit, does without sticks.

White Lady, seed and plant raised here from Salter's Early Blush. Good white Pompon, slightly tinged with blush, grows 2 feet high, flowers 2 inches across. Flowers in September.

Jacintha is an excellent Pompon raised here from seed of Salter's Early Blush, on which it is an improvement, being deeper in colour—a bright pinkish lilac to white, and fuller flower 2½ inches across. Plant 28 inches high, with a rather stouter stem than Salter's Blush. Flowers in September.

Goldsmith, seed and plant raised here. A deep bright yellow Pompon 27 inches high, stout enough to do without sticks. Reflexed flowers 2½ inches across, which come out in September.

Dodo, seed and plant raised here. A pretty little yellow Pompon, very stout and dwarf. A profuse bloomer, 18 to 20 inches high. Flowers 1½ inches across. Flowers in September. Requires no sticks. Good small pot plant. The last five of these are very likely to come earlier next season, as the seed was not sown till March 1st.

Besides the above I have received from the United States quite a number of varieties said to be early, but as many of them came over late in the season and in very bad condition from the voyage, they were not in bloom at the end of October, and can only be tested another season. But I have great hopes of something good, as there are so many raisers. Mr. John Thorpe, in "The American Garden" of October, says: "There are not less than ten thousand seedlings to flower for the first time in the hands of those on the look out for improvements. There are new forms, new colours, better growers, earlier and later flowering varieties." In regard to America, I must thank all friends there, especially Mr. E. H. Libby, of 751, Broadway, and Mr. T. H. Spaulding, who proposes to grow and distribute these early sorts in the United States. I have also this season especially to thank Messrs. Laing for their kind and efficient assistance, not forgetting the English horticultural press.—W. PIERCY, 89, West Road, Forest Hill, London, S.E.

RHODODENDRON FORTUNEI.

THIS Rhododendron has been known for some years in English gardens, but it cannot be said to be either common or frequent, as, except in a few collections where Rhododendrons are specially prized, it is rarely seen. In the Warren Wood Gardens, Hatfield, Herts, the shrub succeeds satisfactorily, as may be judged from the specimen shown in our illustration (fig. 55, page 495) prepared from a photograph obligingly forwarded to us by the gardener, Mr. G. Aslett. In June of this year we called attention to the variety of R. Fortunei raised at Warren Wood.

named Mrs. C. Butler, which is distinguished by the soft pink hue of the wide expanded flowers, in large, loose clusters, and extremely powerful fragrance. It has been grown in the gardens named for several years, and has maintained its character so well for distinctness and free flowering habit that it attracted the attention of many interested in Rhododendrons, with the result that it passed into the hands of Messrs. Paul and Son, of Cheshunt, for distribution. It has been exhibited at the Royal Horticultural Society's meetings, but the flowers are so delicate in texture that they are rarely seen to advantage after being packed for travelling a distance.

EVENTS OF THE WEEK.—The National Chrysanthemum Society's Floral Committee will meet in the Royal Aquarium, Westminster, on Wednesday, December 5th. A General Committee meeting of the same Society will be held in Anderton's Hotel, at 7 P.M., on Monday, December 3rd.

— THE annual meeting of the NATIONAL ROSE SOCIETY will be held at the rooms of the Horticultural Club, "Hotel Windsor," Victoria Street, Westminster, on Thursday, December 6th, for the purpose of receiving the Treasurer's accounts, electing officers for the ensuing year, making arrangements for 1889, and general business. The annual dinner will take place the same day at 6 P.M. at the same place. The chair will be taken by Dr. Robert Hogg, one of the Vice-Presidents of the Society, and a large attendance of members is expected.

— LAST week an action came on for trial before Mr. Justice Denman, and a special jury, in which Mr. F. Sander, of St. Albans, sued the Duchess of Montrose for the amount of £1730 6s. 4d. for Orchids supplied and work done in the conservatory at Sefton Lodge, near Newmarket. Mr. Reid, Q.C., appeared for the plaintiff, and Mr. Philbrick, Q.C., for the defendant, and a number of witnesses were examined, the majority testifying to the fact that the charges were not excessive. The chief amount was for 1000 Orchids at 1 guinea each. In the result the jury returned a verdict for the plaintiff for the full amount claimed, with costs.

— **GARDENERS' ORPHAN FUND.**—The floral concert promoted by the gardeners of Chesterfield and district in aid of the Gardeners' Orphan Charity, which was held at Chesterfield on Wednesday the 14th inst., proved a great success. It was patronised by all the nobility and gentry of the district, and attended by most of them, including some members of our Duke's family. To show the interest taken in the concert, I may say nearly a hundred people travelled from this district in different conveyances, a distance of over nine miles, including about forty garden men in the plant van. There were between 1000 and 1100 people present, and the takings are between £50 and £60. I may say for myself, and for the gardeners who helped me, that we were never engaged in a work which gave us so much pleasure. I hope this may be the beginning of some such efforts on the part of all gardeners throughout the kingdom, when the Gardeners' Orphan Fund would soon become one of the most prosperous charities in the kindom. Making a start is the biggest business: when once the "ice is broken" it is all plain sailing and help flows in on all sides.—OWEN THOMAS, *Chatsworth*.

— **THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.**—Mr. E. R. Cutler informs us that at a meeting of the Committee held on Thursday the 15th inst. it was determined to hold the fiftieth annual general meeting of the subscribers at Simpson's, Strand, on Wednesday, 16th January next, and to add on that occasion fourteen pensioners to the list, five without election under Rule 6, and nine by election among the subscribers. The voting papers will be issued on or about the 15th December. The usual annual friendly dinner of the members will take place after the meeting, and the Very Rev. S. Reynolds Hole, Dean of Rochester, has kindly consented to preside. A special Committee has been appointed to consider the best manner of celebrating the year 1889, this being the fiftieth, or jubilee year, of the Institution.

— **TRADE EXHIBIT.**—We are desired to note that at the recent

Show of the National Chrysanthemum Society at the Royal Aquarium Messrs. Sutton & Sons, Reading, showed 130 varieties of Potatoes, and were awarded a silver-gilt medal, a special prize also being accorded for a similar exhibit at the Crystal Palace.

— WE are informed that a special prize was granted to Mr. J. DIBBER of Dorchester for stands of forty-eight blooms of Chrysanthemums at the late Bournemouth Show. The blooms as the production of an amateur were decidedly meritorious, but arrived too late for exhibiting in the classes for competition.

— THE Committee of the Sheffield and West Riding Chrysanthemum Society have sent a certificate of merit to MR. EDGAR NEWTON Hitchin, for the dry-glazed span-roofed Chrysanthemum house he exhibited at the recent Show. The house, was provided with the new system of ventilation at the eaves, which, like that at the top, is worked by a simple and efficient crank movement.

— WE learn that a special silver medal has been forwarded to MR. G. R. ALLIS, Old Warden, Biggleswade, for Grapes exhibited at the Sandy Show. The medal was provided by Messrs. Wood & Sons, whose manure had aided in their production of the fruit. We believe Mr. Allis has won the first prize at Sandy for eight consecutive years with Buckland Sweetwater Grapes.

— **GARDENING APPOINTMENTS.**—Mr. R. Russell, for many years head gardener at Old Forge House, Dunmurry, Belfast, has been appointed head gardener to T. Montgomery, Esq., Ballydrain House, Belfast. Mr. Alfred Harris, late foreman at Abberley Hall, Stourport, has been appointed head gardener to Sir William Marling, Stan'cy Park, Gloucester. Mr. H. H. Tonkis has been appointed to succeed Mr. McNair at Ilam Hall Gardens, Ashbourne. Mr. John Dixon has been appointed gardener to H. V. Story, Esq., Ruddington Manor, Nottingham.

— IN Messrs. Parker & Sons' nursery at Bristol MIGNONETTE IN POTS is well grown. The strain is a good one, and is being distributed under the name of Parker's New Mignonette, a distinction which it undoubtedly merits, being of sturdy and diffuse branching habit of growth surmounted by spikes of bloom remarkable for their length and stoutness; and also what is popularly looked upon as the chief charm of Mignonette, its delicious scent, is an especially good feature in this variety.—M. C.

— THE first annual Chrysanthemum Exhibition of the BACUP FLORAL AND HORTICULTURAL SOCIETY was held at the Mechanics' Hall, Bacup, on Saturday, November 24th, and was opened at noon by the Mayor (Mr. Alderman Shepherd). Over £50 in prizes were offered, and the Show was well patronised and a great success. Mr. David Lord, Stacksteads, contributed a group of plants, not for competition, which included exceptionally fine plants of Crotons, Dracaenas, Asparagus plumosus nanus, and Orchids, which were specially commended by the Judges. Mrs. Roundell, Gledstone Hall Gardens, Skipton, was highly successful in the open class.

— **PEA WILLIAMS' EMPEROR OF THE MARROWS.**—This is by far the best late Pea that has yet come under my notice. In ordinary seasons it grows to a height of 6 feet, this year they exceed this by 2 feet. It is of a branching habit, an enormous cropper, the pods large and well filled, the flavour of the peas is all that can be desired. A long row of this variety was sown here on the 22nd of June last. We commenced to gather from them on September 29th, and to my great delight, with the exception of the first week in October we have got two good gatherings of Peas from this row each week up to November the 17th, the last gathering being made on the latter date. Green Peas in the middle of November is not, I believe, a common occurrence even in the salubrious climate of Ireland.—R. WELLER.

— A CORRESPONDENT states that the annual Show of the HESSLE CHRYSANTHEMUM SOCIETY was held in the Assembly Rooms on the 16th inst., when there was a good display of cut blooms, groups, and bouquets, which were of great merit. In the open class for twenty-four cut blooms, twelve incurved and twelve Japanese, R. Soames, Esq. (Mr. J. Walker, gardener), Waltham Hall, Grimsby; A. Wilson, Esq. (Mr. J. Leadbetter, gardener), Tranley Croft, Hull; and Mr. Whittaker, Hessle, were the prizetakers. For twelve, six incurved and six Japanese, Mr. R. Soames was again to the fore with excellent blooms, and Mr. King, Ferribe, second. The amateur classes were well filled, and the exhibits of excellent quality. The groups were creditably arranged, but the exhibitors' collections had evidently suffered from the early frosts which prevailed in the district about October 1st and 2nd. The arrangements were admirable.

— THE second Show of the BOLTON CHRYSANTHEMUM SOCIETY was held in the Town Hall, November 23rd and 24th, and, despite the unfavourable season, the Show was a very creditable one, the main features being the groups in the miscellaneous class. Thomas Wilkinson, Esq., (gardener, Mr. John Pountain) won first honours with a well-arranged collection. Mrs. Shaw (gardener, Mr. Charles Jones) was a good second; John Heywood (gardener, Mr. George Pawson) being third. In the class for groups of Chrysanthemums there were five entries, J. C. Ormrod, Esq. (gardener, Mr. R. Smith) being first with a well arranged collection. Mrs. Knowles (gardener, Mr. Thomas Hand) was second with dwarf well grown plants, but packed together too closely. Of cut flowers the twelve incurved and twelve Japanese from Arthur Knowles Esq. (gardener, Mr. George Corbett) were decidedly the best, and were first in both classes. Good Grapes were also shown by Mrs. Cross (gardener, Mr. R. Herd).

— THE WAKEFIELD PAXTON SOCIETY.—At the usual weekly meeting of the members of this Society, held at the "Saw Hotel," Councillor Milnes, the President, occupied the chair, and Mr. Arthur Goldthorpe, one of the Vice-Presidents, the vice chair. There was a good attendance. Mr. West of Rotherham read an exceedingly interesting paper entitled "Insects Parasitical on Plants." Mr. West, who is a skilful gardener and a clever naturalist, pointed out in a very clear and intelligent manner those insects which are specially injurious to plants, dwelling more particularly on the caterpillars, moths, and butterflies, a collection of which he exhibited. A discussion followed the lecture, in which Messrs. A. Goldthorpe, G. Gill, W. Calvert, G. Parkin, T. Garnett, and others took part, and at the close a very hearty vote of thanks was awarded to the essayist on the motion of Mr. A. Goldthorpe, seconded by Mr. G. Gill. A pressing invitation was given to Mr. West to pay another visit to Wakefield, and he acceded to the invitation.

— TORREYA MYRISTICA.—In any collection of Conifers the above-named deserves a place, not so much on account of its appearance as a tree, for as such it cannot be compared with many of the beautiful Pines and Piceas, but it is worth planting for the sake of its curious appearance when in fruit, especially from July to the end of October. A plant in the collection here, about 20 feet in height and the same in diameter of branches, has borne fruit regularly the last eleven years, some years more abundantly than others; but this year I have never seen it better, many hundreds of its curiously Nutmeg-shaped fruit, about 1½ inch long, having been produced near the extremities of the branches, giving the tree a quite distinct appearance from any other Conifer. A thick husk similar to a Walnut encloses the solitary fruit, and when ripe peels off in the same manner. This husk has an unpleasant and peculiar smell, and has, no doubt on that account, been called the Fœtid Yew. It is a native of California, and is said to attain a height of 40 or 50 feet. It thrives well with a gravel subsoil, and is very hardy, our winters not appearing to injure it at all. Its wood seems hard and durable like the Yew, but the trunk is small in comparison with the spread of branches. —A. HARDING, *Orton Hall, Hunts.*

— CIDER AND PERRY FRUITS IN PARIS.—The Exhibition in connection with the manufacture of cider and perry, which is now being held at the Palais de l'Industrie in Paris is drawing to a close, and the jury have just finished their labours in the section for fruit, as well as that for cider and perry. Among the awards Devonshire gets a fair share, for Messrs. Robert Veitch & Son of the Royal Nurseries, Exeter, have gained the gold medal and diploma (first prize) for cider Apples, while the second prize for cider has been won by Mr. Charles Ham of Exeter, a minor prize for Apples also going to Mr. Ham. The sorts shown in Messrs. Veitch's collection are those mostly grown in Devonshire orchards for cider making, and include such varieties as Slack-my-girdle, Tom Putt, Pound Apple, Sweet Albert, Hanwell Souring, Sweet Alfred, Farmer's Glory, and other well known cider fruits. There were fifty-one dishes in all, and were a good representative collection. The report will be published later on, when, no doubt, some information will be forthcoming as to the comparative merits of British and foreign fruit for manufacturing purposes. In the meantime it is a matter for congratulation that the county of Devon, so famous for its cider, has maintained its prestige as an Apple-growing county.

— THE ENGLISH ARBORICULTURAL SOCIETY.—The annual meeting of the above Society was held on Saturday last in the Victoria Hall, Carlisle, Cadwallar Bates, Esq., in the chair. The accounts were examined and passed. Sir John Lubbock was elected President, R. J. Davidson, Haydon Bridge, Secretary and Treasurer, and Mr. J. Baldwin, sen., Dilston, and Mr. Bernard Cowan, South Shields, Auditors. In the

interest of the Society it was deemed advisable to hold the summer meeting at Windsor in the week of the Royal Agricultural Society, and the annual meeting at Darlington. Mr. Wilson, Leazes Park, Newcastle, was awarded the bronze medal of the Society for an essay on "Suitable trees for various soils and situations." An interesting discussion was initiated by the President on the planting on barren and waste lands, which was ably carried on by Mr. J. Watt and Mr. Wm. Clark. Mr. J. Watt paid Mr. J. Baldwin, jun., a well deserved compliment on the able paper he had read before the Society on tree planting as one that was of national importance. This was further elucidated by the Secretary, who stated that the Greenwich Commissioners had some land thirty years ago that would not let for 2s. an acre. This had been planted, and the timber recently cut had yielded a net profit of nearly £60 per acre. The meeting concluded with a hearty vote of thanks to the retiring President.

— ROYAL METEOROLOGICAL SOCIETY.—The first monthly meeting of this Society for the present season was held on Wednesday evening, the 21st instant, at 25, Great George Street, Westminster, Dr. W. Marcet, F.R.S., President, in the chair. Senor A. Arcimis, Mr. J. W. Gray, Dr. J. L. Green, Mr. R. T. Morgan, Mr. C. E. Mumford, Mr. E. S. Oxenham, F.R.G.S., Dr. A. M. Robertson, Dr. E. Seaton, Mr. J. N. Sidebotham, and Dr. T. C. Squance were elected Fellows of the Society. The following papers were read:—1, "Results of an Investigation of the Phenomena of English Thunderstorms During the Years 1857-59," by Mr. G. J. Symons, F.R.S. This paper was written nearly thirty years ago; it has now been communicated to the Society at the request of the Thunderstorm Committee. The paper contains a summary, chiefly in statistical form, of some of the results of an investigation into English thunderstorms and the accidents produced by lightning during the years 1857-9. The author found that in sheet lightning the most prevalent colour is white, then yellow, blue, and red. In forked lightning the order is nearly reversed, blue being more than twice as frequent as any other colour, then red, white, and most rarely yellow. Sheet lightning was seen about twice as often as forked. 2, "Notes on the Meeting of the International Meteorological Committee at Zurich in September, 1888," by Mr. R. H. Scott, F.R.S. The Committee recommended certain rules for the publication of data by travellers, &c., so as to ensure their being useful for the advancement of sound climatological knowledge. The proposals for an international cloud nomenclature, as recommended by Mr. Abercromby and Prof. Hildebrandsson did not commend themselves to the Committee, who suggested that the subject should be further studied. At the conclusion of the meeting the Committee was dissolved. 3, "On a Method of Photographing Cirrus Clouds," by Dr. A. Riggenbach. The author exhibited some photographs of cirrus and other fine clouds which had been obtained by using the surface of a lake as a polarising mirror. Mr. A. C. Stratten exhibited some models of very large hailstones, spheres about 2½ inches in diameter, which fell at Montereau, about forty miles south-east of Paris, on August 15th, 1888.

CHRYSANTHEMUM SHOWS.

WE have again to express our thanks to many correspondents who have favoured us with brief reports of shows, some of which, however, we have been compelled to still further abbreviate. We have also received newspaper reports of the following Shows:—Pembroke, Lymington, Nottingham, Chesterfield, Loughborough, Highgate, and Chorley, for which, unfortunately, we cannot find space.

CLONMEL.—NOVEMBER 13TH.

THIS Show was held in the large Assembly Room of the Courthouse, Clonmel. Notwithstanding the generally unfavourable season, and that almost all the local growers lost some of their finest blooms through premature damping-off, the Show must be pronounced an unexpected success. Much of this is due to the tact and energy of the courteous and efficient Secretary, Mr. Thomas Phelan of Spring Gardens, and the other members of the Committee, but especially Messrs. Frederiek Clibborn, Anner House, and H. S. Boyd, Suirmont, who were indefatigable in perfecting the preliminary arrangements.

The requirement for admission into the group section was that competitors were each to furnish a sufficient number of plants to occupy a space of 60 square feet, and the prize was to be awarded only to that collection which should best illustrate quality and effect. All the collections were highly meritorious, the prizes going ultimately to Mrs. Malcomson, Minella, Clonmel (head gardener, Mr. John Crehan); second, Thomas Phelan, Esq., Spring Gardens (Mr. Halpin); and highly commended, Dr. W. H. Garner (Mr. O'Shea). Conspicuously good in the first were Golden Queen, Balmoreau, Criterion, and Val Andore, and in the second Cullingfordi, La Frissure, and Sœur Dorothee Souille. The next class was six plants in pots—old plants being disqualified—grown on a single stem. The first prize went to Mr. Phelan, and second to

Mrs. Malcomson. In the class for trained specimen, Mrs. Malcomson came first with a good Mrs. Forsyth (white Christine).

For twenty-four incurved blooms, not less than nine varieties. After close competition the first prize went to Mr. Raymond de la Poer of Kileronagh, Kilkenny (gardener, Mr. Crawford), and second to Mr. Thomas Phelan. Particularly good in the first were Cherub, Princess of Wales, Lord Alcester, and John Salter; and in the second exhibit Jardin des Plantes, Prince Alfred, and Lord Wolsley. For twelve incurved there were five entries, and after careful "pointing," Mr. F. Clibborn (Mr. Crowley) was placed first, Mr. Malcomson second, and Dr. Garner highly commended. In the first Jeanne d'Arc, Golden Empress, and Blush Queen were particularly noticeable, and in the second were Novelty, Lord Wolsley, and Blush Queen. Next came twenty-four Japanese, and for this the competition was close between Mr. R. de la Poer, Mr. T. Phelan, and Dr. Garner, but ultimately the prizes went in the order named. The more remarkable blooms were almost similar to those in the cup class, which we propose to give fully. Then came the class for twelve Japanese, and this was the most closely contested at the Show, first prize ultimately going to Mrs. Malcomson, with grand blooms of M. Tarin, Fanny Bouchardat, Dormillion, Val d'Andorre, and Elaine—very fine. Mr. Clibborn was second with Edwin Molyneux, Ralph Brocklebank, and Gloriosum, among others. Mr. H. S. Boyd was highly commended, while two other stands were very little behind in point of merit. In the reflexed class Mr. de la Poer had again the premier position, with some fine blooms of the golden, white, and pink Christine, Cullingfordi, and King of Crimson. Mrs. Malcomson was second, and Mr. Phelan highly commended. Grandly shown by Mr. Phelan was Amy Furze, a decided acquisition. In Anemone Japanese, Mr. de la Poer once more was peerless, while in Pompons Mrs. Malcomson and Mr. Boyd divided the honours in the order named.

In the incurved section the best bloom in the Show was adjudged to Raymond de la Poer's Princess of Wales (a perfect bloom), Mrs. Heale almost disputing the honour in the same stand. In the Japanese the premier position went by general consent to the new introduction, Ralph Brocklebank, in Mr. Clibborn's collection, next coming the very telling variety, Edwin Molyneux.

The silver cup, value £5, given by Raymond de la Poer, Esq., was the chief prize of the Show, and for it there were entered five stands of twenty-four each, incurved and Japanese, to contain eighteen distinct varieties, by the donor, Mr. F. Clibborn, Mrs. Malcomson, Dr. Garner, and the Hon. Dudley F. Fortescue, Summerville, Waterford. After each stand had been pointed, closely inspected, and the points of merit added up, the first stand was found to have 128 points, the second 114, and the third 111—the cup, with first prize, and the second and third prizes going in the order named. As growers will be anxious to add to their collections, we give the names of the varieties which "The cup" stand comprised—Incurved—Lord Alcester, Bronze Queen, Golden Empress, Princess of Wales (perfect), Blush Queen, Mrs. Heale (very fine), John Salter, Refulgens and Cherub (a grand bloom); and the Japanese—Edwin Molyneux, Meg Merrilies, Jeanne Délaux, Criterion, Comte de Germiny, M. Freeman, Marguerite Marrouch, Golden Dragon, Mrs. H. Cannell, and Balmoreau, all very telling and effective as arranged. Mr. de la Poer, having been declared the winner of the cup, not wishing to retain the prize he had himself presented, handed it back most generously to the Committee to be competed for next year.

At this late time of the year the fruit competition was necessarily limited, still the Show was very creditable. For the best Grapes Mr. F. Clibborn was first for five bunches of Black Hamburg and Trebbiano, the Honourable Dudley Fortescue second; while those shown for Mrs. Malcomson were very highly finished. This lady also came first for dessert Apples and baking Apples; while Mrs. Crean of Coolgreany had similar honours for the best Pears.

Besides those exhibited in the various sections there was a beautiful display of other flowering and foliage plants kindly sent in from some of our local conservatories for the purpose of adding still further to the attractive appearance of the room. George Gough, Esq., Birdhill, contributed some beautiful Orchids in flower.

HAMPSTEAD.—NOVEMBER 14TH.

THE eighth annual Exhibition of Chrysanthemums was opened by Lady Onslow in the Vestry Hall, Haverstock Hill, on the 14th. A miscellaneous group of plants most tastefully arranged by Mr. Tribe, gardener to H. M. Matheson, Esq., which had a grand effect on coming into the hall. The group consisted of Palms, Chrysanthemums, Roman Hyacinths, &c. The principal class was for cut blooms (open), eighteen incurved and eighteen Japanese. First, Mr. S. Bell, gardener to P. D. Duckett, Esq.; second, Mr. A. Aitkins, Linden House Gardens, Highgate Road; third, Mr. D. Hayter, gardener to W. Hannsford, Esq., Hendon, only three points dividing each exhibitor. The names of the varieties in the winning box were—Incurved—Queen of England, Golden Queen, Prince Alfred, Jeanne d'Arc, Emily Dale, John Salter, Guernsey Nugget, Bronze Queen, Empress of India, Golden Empress, Alfred Salter, Princess of Wales, Lord Wolsley, Mr. Bunn, good; Mr. G. Glenny, Lady Talford, Mrs. Dixon, and Lord Alcester. Japanese—Belle Paule, Criterion, best flower in the Show; Mons. Tarin, Val d'Andorre, Mlle. Lacroix, Soleil Levant, Japonaise, Marguerite Marrouch, Mad. B. Rendatler, Albert, Peter the Great, Maiden's Blush, Madame de Sevin, M. J. Laing, M. Astorg, Comte de Germiny, Madame C. Audiguier, and Triomphe du Nord.

Some very fine groups were well shown by Mr. Powley, Mr. Coleman, and Mr. Small. Bouquets were shown by Mr. Harris, first; second,

Mr. H. Ellison; third, Mr. G. Coleman, and the exhibits were very numerous and good. Great thanks are due to the Honorary Secretary, Mr. Anderson, Mr. R. Frisby, Mr. Ings, &c., for the way in which the Show was arranged.

FAVERSHAM.—NOVEMBER 14TH AND 15TH.

THE second annual Exhibition of this Society was in every way a grand success, and proves what can be done in two seasons towards bringing a Society into the front ranks of Chrysanthemum shows. Of course, to a great extent, the success is due to the excellent management, and to the energy thrown into the Society by the courteous Secretary, Mr. C. Stidolph. The Faversham Institute had been secured for the Exhibition, but so numerous were the entries that arrangements had to be made for the use of the smaller hall for fruit and vegetables, in addition to the large room, which was almost entirely occupied with groups of Chrysanthemums, trained plants, and cut blooms. In the class for twenty-four blooms, so close were Mr. Ray and Mr. Thomas, that the Judges awarded them equal first, Mr. Cornford was third. Mr. McLaren secured the bronze medal of the N.C.S. for a grand bloom of Lord Wolsley, and Mr. Weller gained the N.C.S. certificate for a well-finished bloom of Grandiflorum. Trained plants were exhibited by Mr. Cook, Mr. G. T. Anderson, Mr. McLaren, and Mr. Creed.

The amateur classes for cut blooms were exceedingly well filled, and the competition was most keen, and the majority of the blooms exhibited by the Faversham amateurs would not have disgraced the boards of some of our leading exhibitors at the big shows. Mr. L. Jackson, the Treasurer, is a most successful grower, followed closely by Mr. Hill, Mr. C. Stidolph, and Mr. H. Dan. Mr. E. Hill's bloom of Emily Dale, for which he was awarded the N.C.S. medal as the best incurved in the Show, was a perfect model. Mr. L. Jackson secured first honours for the best Japanese bloom, a superb flower of Meg Merrilies. In the cottagers' classes some very fine blooms were exhibited, and Mr. T. Terry secured the N.C.S. bronze medal for a bloom of Eve, which was declared by the Judges to be one of the finest flowers of this variety they had seen this season. Mr. G. Lewis was first with a magnificent Thunberg. Numerous exhibits were staged not for competition, amongst them being a stand of forty-eight dissimilar blooms of excellent quality exhibited by Mr. Fred T. Hart of Faversham, amongst them being Amy Furze, Mdlle. Paul Dutour, very fine; Charles Orchard, Edwin Molyneux, very large; Duke of Berwick, and some grand Queens and Empresses. The show of vegetables was declared to be one of the finest in the county, and attracted considerable attention. The successful exhibitors were, Mr. C. Ivory, Mr. Aekhurst, Mr. Trisker, Mr. G. Lewis, Mr. A. Matson, Mr. Burton, &c.

The class for the silver challenge cup given by Messrs. Lyddon for the best group of Chrysanthemums brought out some fine exhibits, and great credit is due to the winner, Mr. H. Louth, for both the quality of his individual blooms and the arrangement of his group, his tallest plants being about 4 feet 6 inches, sloping down to front row plants less than 2 feet high. Mr. C. Cornfoot was second, and Mr. W. Ratcliff third. Mr. Fred T. Hart also exhibited a very fine collection of Potatoes, twenty-seven varieties, which were very highly commended.

Fine weather favoured the Exhibition, and the rooms were thronged with visitors the whole time they were open.

MARKET HARBOUROUGH.—NOVEMBER 14TH AND 15TH.

THE Market Harborough and District Chrysanthemum Society held their annual Show on Wednesday and Thursday, November 14th and 15th, and the Committee is to be congratulated on the success which has again attended them in bringing together so grand a collection of the favourite autumn flower. The specimen plants in the incurved and Japanese were very good. The entries for cut blooms were numerous, and so great was the merit of the different exhibits that the task of judging was a difficult one. The chief feature of the Show, however, was the arrangement of the groups, six of which were in competition. These were placed three on each side of the room, and flanked by groups of miscellaneous plants, the whole forming as pretty a picture as the eye of the most critical might wish to rest upon. The band stand, too, was very effectively decorated, two magnificent Palms standing on each side, their spreading leaves extending over the heads of the bandsmen. In front of these in the centre of the platform was a collection of cut Chrysanthemums arranged as a miniature group by Mr. John Dille, gardener to W. H. Hay, Esq., Bowden Hall, and this came in for an unusual amount of notice, and was much admired. Round the remaining portion of the platform were placed boxes of cut blooms backed by Solanums.

The majority of the first prizes for plants were taken by S. Symington, Esq., Brookland House, Market Harborough (gardener, Mr. H. Dunkley). For the group Messrs. Plowman & Son were again awarded premier honours; R. H. P. Hutchinson, Esq., Husband's Bosworth (gardener, Mr. W. Rainbow), being second; and G. H. K. Fisher, Esq., Harborough (gardener, Mr. W. Norman), third. In cut blooms, Mr. S. Symington, W. Symington, Esq. (gardener, Mr. J. Clarke), G. L. Watson, Esq., Rockingham Castle (gardener, Mr. H. Watt), and Sir F. F. Turville, K.C.M.G. (gardener, Mr. W. Duncan), were the most successful exhibitors.

The exhibits in class B for amateurs were much better than at any previous Show, the most admired being the plants of Mr. S. Branstion and the groups of Messrs. Bott, Branstion, and Dalby. Class C for cottagers also showed a marked improvement on last year. It may be added that a show of vegetables was held in connection with the

above in another room of the Corn Exchange, and this was a remarkable success, no less than twenty-three collections being exhibited in addition to a very large entry for the other prizes.

YORK.—NOVEMBER 14TH, 15TH AND 16TH.

THE annual Chrysanthemum Exhibition of the Ancient Society of York Florists was held in the Fine Art and Industrial Institution on the above dates. Collectively, and making allowance for the trying season of 1888, the Show was the best yet held by the Society. Specimen plants were as numerous and nearly as good as in previous years. Groups of Chrysanthemums and foliaged plants were superior to the average, and the competition was very close between several exhibitors, and groups of Chrysanthemums only were proportionately good. Probably the most decided advance was in the classes for cut blooms, and here the contest was very keen. For thirty-six flowers—eighteen incurved and eighteen Japanese in not less than twelve varieties of each—the contest was somewhat unequal, one exhibitor having a decided lead with incurved varieties, the other with Japanese, and superficially it appeared as though the winner of the second prize ought to have occupied the premier position; but such was not the case when every flower in each stand had been most carefully valued and "pointed" by the Judges. So good were the incurved flowers of W. B. Richardson, Esq. (gardener, Mr. Folkard) that they "pointed" 97.6 points out of a possible 108; whilst the Japanese of H. J. Robinson, Esq. (gardener, Mr. Osborne), Woolton, Liverpool, only score 90.9 points out of a possible 108. The total number of points obtained by Mr. Richardson was 180.3, and the number by Mr. Robinson 176.3; therefore, Mr. Richardson won by exactly four points, and to him was rightly awarded the premier prize of a silver cup and £5 in cash. Across the lower end of the Hall was a magnificent display of Grapes, Mr. Goodacre of Elvas-ton figuring with his usual success, taking the first prize for six bunches of Grapes. In the side galleries was the usual excellent display of vegetables and hardy fruits. The Committee, and especially the Secretary and Treasurer, to whose untiring energy and courtesy the continued success must in no small degree be attributed, are to be congratulated on again having one of the most beautiful displays of flowers, fruit, and vegetables to be seen in this country. The following are the principal prizewinners:—

PLANTS.—Group of Chrysanthemums, interspersed with foliage plants arranged for effect, occupying a space of not more than 100 square feet.—First, T. M. Weddall, Esq. (gardener, Mr. Kendall), second J. H. Hingston, Esq. (gardener, Mr. McIntosh), third Mrs. Gutch (gardener, Mr. Everard), fourth Mr. Makins (gardener, Mr. Stephenson). Group of Chrysanthemums arranged for effect, occupying not more than 64 square feet.—First A. Milnthorpe, Esq. (gardener, Mr. Anderson), second Mrs. Cowl, third J. Melrose, Esq. (gardener, Mr. J. Richardson), fourth Mr. T. Smith. Specimen plants.—First Mrs. Gutch (gardener, Mr. Veary), Miss Steward, J. H. Hingston, Esq.

CUT FLOWERS.—Thirty-six, eighteen incurved and eighteen Japanese, in not less than twelve varieties of each.—First W. B. Richardson, Esq., Elm Bank, York (gardener, Mr. Folkard), second H. J. Robinson, Esq., Aymostry Court, Woolton, Liverpool (gardener, Mr. Osborne), third A. Wilson, Esq., Hull (gardener, Mr. Leadbetter). Twenty-four, twelve Japanese and twelve incurved.—First W. B. Richardson, Esq., second G. Whitehead, Esq. (gardener, Mr. Hebden), third Miss Steward. Twelve Japanese.—First A. Milnthorpe, Esq., second Mr. T. Smith, Norwood Nursery, Beverley. Twelve incurved.—First W. B. Richardson, Esq., second Miss Steward.

For fruit the prizewinners were Mr. Goodacre, H. C. Neville, Esq. (gardener, Mr. Hare), Lord Hotham, W. B. Richardson, Esq., Mr. J. W. Hutchinison, and Mrs. Mellish, Hodsock Priory, Worksop (gardener, Mr. Mallender).

The vegetables were of first class quality, and the principal prize-takers were Messrs. Kirk, Kingston, Whitehead, Hardcastle, West, Hudson, Benson, and others. Mr. T. B. Morton of Darlington had a capital collection of Chrysanthemums not for competition, and several new varieties were certificated.

READING.—NOVEMBER 15TH.

READING always furnishes a very fine Exhibition of Chrysanthemums; and this Exhibition was no exception, although for obvious reasons the competition was scarcely so extensive and keen as heretofore. But there were enough exhibits to fill the two Town Halls, and very gay they looked, despite the dull weather. Although it rained the greater part of the day the Show was well attended, and the takings at the gates exceeded that of last year. The Chrysanthemum Exhibition is quite distinct from those of the Reading Horticultural Society, the Hon. Secretary being Mr. R. D. Catchpool, who deserves the highest credit for the success, financial and otherwise, which always attends the Exhibitions.

There were nine groups of Chrysanthemums of thirty plants placed around the sides of the old Town Hall, and the light being only on one side of the building made it somewhat difficult to judge them. It was a very close run between Mr. Perkins, gardener to the Rt. Hon. W. H. Smith, M.P., Greenlands, Reading; and Mr. Turton, gardener to John Hargreaves, Esq., Maiden Erlegh, Reading, the two leading awards were made in the order of the names. Mr. Perkins had the dwarfest plants, well grown, carrying flowers of high quality. Mr. Turton's plants had very fine blooms mainly of Japanese varieties, but there were features of coarseness, and there was a lack of general effect. Mr. Hawkins, gardener to W. Cowslade, Esq., Erlegh, was third, and four other

prizes were awarded. The Judges recommended that for the future the exhibitors should be allowed to place a margin of Palms, Ferns, and such like as a front line to the groups, thereby heightening the general effect.

The only six specimen plants, Japanese excluded, came from Mr. Surman, gardener to C. H. Witherington, Esq., Sonning, his best varieties being Mr. G. Rundle, Dr. Sharp, Prince of Wales, and Mr. Dixon. Mr. Booker, gardener to R. Tomkins, Esq., Reading, had the best three, staging Mr. Dixon, Mr. G. Rundle, and Empress of China. Mr. Franklin, gardener to F. Lucas, Esq., Sonning, was second. Mr. Surman had the only six Japanese, having admirably grown and bloomed plants of Mdle. Lacroix, Madame Bertie Rendatler, Bouquet Fait, Red Dragon, James Salter, and Lady Selborne. Mr. Powell, gardener to G. Gilligan, Esq., Reading, had the best three plants in Elaine, Val d'Andorre, and Red Dragon. Mr. Franklin was second. Mr. Surman had the best three Pompons, Mr. Franklin being second. The specimens might have been better. Mr. Booker had the best standard, showing Mdle. Marthe; Mr. W. T. Abery, nurseryman, Tilehurst, being second with its golden form.

Chrysanthemums grown as window and later plants were a good feature, dwarf specimens 12 to 15 inches in height carrying a few good flowers. Mr. Surman had the best six large flowered, showing Bouquet Fait, Mr. Dixon, Mr. G. Rundle, James Salter, Lady Selborne, and Madame Bertie Rendatler. Mr. Franklin was second, and Mr. Armitage, gardener to H. Clarke, Esq., Reading, third. Mr. Franklin had the best three Pompons grown in this way, Mr. Surman coming in second. A peculiar feature at Reading is standard Chrysanthemums with circular, flat, or shelled-shape heads to face the spectator. Mr. Armitage had the best three, Mr. Booker being second. Mr. Abery had the best single standard; Mr. Hinton, gardener to J. Leslie, Esq., Reading, being second; but it is a somewhat unnatural type of plant growth.

Some very fine blooms were staged, and the leading stands of incurved flowers showed great refinement. The best eighteen came from Mr. Allen, gardener to Sir G. Russell, Bart., M.P., Swallowfield Park, Reading, who had grand blooms of Lord Alcester, Alfred Salter, Jeanne d'Arc, Lord Wolsley, Princess Alexandra, Jardin des Plantes, Golden Empress, Prince Alfred, Lord Eversley, Queen of England, Princess Teck, Cherub, Bronze Jardin des Plantes, Empress Eugénie, Bronze Queen, Emily Dale, Barbara, and Mrs. Heale. Second, Mr. Neville, gardener to F. W. Flight, Esq., Twyford, Hants; third, Mr. Lane, gardener to Miss Dunning-Smith, Ascot. Mr. Brooks, gardener to H. A. Simonds, Esq., Andover, had the best twelve, Mr. Baskett being a good second, and Mr. W. Lees, third. A very fine stand of twelve reflexed in eight varieties came from Mr. Allen. Stands of twelve Japanese in not less than eight varieties were numerous and very fine also, Mr. Lane being placed first with E. Molyneux, Madame B. Pigny, Val d'Andorre, Soleil Levant, Madame J. Laing, Criterion, Belle Paule, Ralph Brocklebank, Jeanne Délaux, Thunberg, Sarah Owen, and Avalanche. Mr. Baskett had the best twelve Anemone flowered, not less than eight varieties. Mr. Allen had the best twelve blooms shown with 9 inches of stem, staging fine specimens, comprising Lord Alcester, Lord Wolsley, Empress of India, Golden Empress, Madame G. Pigny, Thunberg, E. Molyneux, Jeanne Délaux, and Madame J. Laing, two or three being shown in duplicate; second, Mr. Ashman, gardener to C. Crews, Esq., Billingbear Park, Reading. Mr. Surman had the best six bunches of Pompons, staging President, Adele Priset, White Trevenna, St. Michael, Sœur Melanie, and Rose Trevenna.

Table decorations and vases are always a delightful feature at Reading. Mr. Abery had the best vase for drawing-room. Large hall vases were an imposing feature, Mr. Abery had the best, Mr. Brooks was second. Miss Phillips of Reading had the best arrangement of cut flowers and foliage, staging one done in excellent taste, Mr. House being second. Miss L. Phillips had the best arrangement in autumn foliage and berries, putting up a basket charmingly finished. Mr. G. Phippen, nurseryman, Reading, had the best ballroom bouquet of Chrysanthemums. Vases of Everlastings were a pleasing feature also.

There was a good display of fruit. Mr. Jennings, Forest Lodge, Farnborough, had the best two bunches of Alicante Grapes, well coloured and fine in berry, Mr. Cooper of Sunninghill being second, and Mr. Prowse, gardener to E. L. Lawson, Esq., Beaconsfield, third. Mr. Ashman, Billingbear Park, had the best two bunches of Gros Colman, extra fine and well coloured; Mr. Cooper was second with good examples, and Mr. W. Lees third. Mr. Lees had the best two bunches of any other black, staging Madresfield Court, a little loose in bunch but fine in colour; Mr. Paston, gardener to the Hon. C. S. Ivey, Taplow, being second, with well finished Gros Maroc, Mr. Jennings being third with good Lady Downe's. Mr. Dockerill had the best two bunches of White Muscats, very fine and clean. Mr. Perkins came second with larger bunches and smaller berries. In the class for any other white kind Mr. Turton was first with excellent Trebbiano, large in bunch and of fine quality, Mr. Lees being second.

The class for six dishes of English dessert fruits brought out one exhibitor, Mr. Perkins, who had good White Muscats and Alnwick seedling Grapes, Melon, Bananas, Cox's Orange Pippin Apple, and Fovelle Pears. Mr. Turton was first with six dishes of dessert Apples. Mr. Perkins also had the best dish of Cox's Orange Pippin. Mr. Turton, led with six dishes of culinary Apples.

Of miscellaneous exhibits Mr. J. Watkins, Pomona Farm, Hereford staged seventy-five dishes of Apples, many of them very highly coloured, and Mr. R. Owen, nurseryman, Maidenhead, a stand of new Chrysanthemum, including John Thorpe, dark cerise, and George Daniels, light

pink broad petals, but wanting in shape. A first class certificate of merit was awarded for the Japanese Fimbriatum, blush tinted with lilac, shown in very fine form.

ALVERSTOKE AND GOSPORT.—NOVEMBER 15TH AND 16TH.

THE first Exhibition of this recently established Society was held at the new Thorngate Hall, Gosport, and in spite of the many other counter-attractions it must be pronounced a decided success. The leading groups of Chrysanthemums bore heavy fresh blooms of first rate quality. The specimen plants were a weak feature, but the stands of cut blooms of Messrs. W. & G. Drover, and the two or three other successful prizewinners elevated the quality far above the average of newly established societies' plants. For six natural trained specimens on single stems Mr. Hawkins, gardener to E. Laphorne, Esq., Gosport, was awarded first; Mr. J. Groom, nurseryman, Gosport, second; Mr. F. Limburn, gardener to Mrs. Lane, third. Mr. Hawkins was also first for Pompons.

In the class for a group of 30 square feet Mr. Gale, gardener to

distinct, Mr. Hawkins was first with a stand of good solid blooms of Golden Empress, Jeanne d'Arc, Empress of India, Princess of Wales, Queen of England, Venus, Lord Wolseley, Princess Teck, Mrs. Heales, Mr. Brunlees, White Venus, and Emily Dale. Second, Mr. Limburn. Third, Mr. E. Foot, gardener to H. C. Martin, Esq., Mr. Gale being again disqualified in this class for the same reason as mentioned concerning the previous class. In the corresponding class for twelve Japanese, Mr. G. Hawkins exhibited a fresh and even lot of blooms of the following varieties:—Baronne de Prailly, Carew Underwood, Madame C. Audiguier, Fair Maid of Guernsey, Gloriosum, Mons. Tarin, Marguerite Marrouch, Duchess of Albany, Val d'Andorre, Bouquet Fait, Madame Baco, and Dormillion. The second went to Mr. King, gardener to W. H. Fry, Esq., and the third to Mr. Foot. For twelve reflexed, six varieties, Mr. Hawkins was awarded first, with good blooms of Cullingfordi, Madame Madeleine Tezier, Pink Christine, Chevelier Domage, Amy Furze, Golden Christine, and King of Crimson. Mr. Limburn was second with a good lot, containing a fine bloom of the old variety Progne. Mr. Gale was third. For twelve large Anemones, six varieties, Mr.

FIG. 35.—RHODODENDRON FORTUNEI. (See page 490).

G. Cooke, Esq., Gosport, was well ahead with a good lot, containing excellent blooms of incurved and Japanese varieties, but as is usual in small groups, the front plants were rather tall and deficient of foliage. The second was awarded to Mr. Hawkins for dwarfier but well-finished plants of good average quality, and the third to Mr. J. Long, gardener to Mrs. Walton.

In the open class for twenty-four cut blooms, distinct, twelve incurved and twelve Japanese, Messrs. W. & G. Drover, Fareham, were well to the front with a splendid sample, consisting of incurved:—Back row—Golden Empress, Empress of India, awarded the prize for premier incurved bloom in the Show; Alfred Salter, Lord Alcester, Nil Desperandum, Empress Eugénie, Mrs. Heales, Chas. Gibson, Princess Teck, Mrs. Norman Davis, Prince Alfred, and Jeanne d'Arc. Japanese: back row—Boule d'Or, Belle Paule, Edwin Molyneux, Meg Merrilies, Baronne de Prailly, Avalanche, Ralph Brocklebank, premier Japanese; Madame Baco, Gloriosum, Jeanne Delaux, Marguerite Marrouch, and Criterion. Mr. Agate, florist, Havant, was second with good blooms. Third, Mr. Limburn. Fourth, Mr. Hawkins. Mr. Gale exhibited a good stand of blooms in this class that would have taken a prize, but was disqualified through having two blooms of Empress of India, under the names of Snowball and Isabella Bott. In competition for twelve incurved,

Hawkins had a good stand, and was awarded first prize. Mr. Limburn second, with Mr. Foot third. The stands of twelve Pompons were noteworthy through the competition being confined to twelve varieties, with three flowers on one stem, a good way to test the merits of the varieties. Mr. Hawkins was awarded first, and Mr. Foot second.

The vegetables brought out for competition was sufficient to fill a table across the end of the hall, which made a very imposing show. For nine distinct dishes Mr. Hawkins was first with a good lot, the Cauliflowers, Carrots, and Beet being very good. Mr. Limburn was second, Mr. J. Long third; fourth Mr. Shelley, gardener to Capt. Sir Alfred Balliston, R.N., and extra prizes was awarded to Mr. Foot and Mr. W. Smith. In the special class for prizes offered by Messrs. Cutbush and Son, Highgate Nurseries, London, for eight dishes, Mr. Hawkins was again first with an excellent exhibit, Carrots, Parsnips, and Cauliflowers being clean and good. The competition for prizes offered by Messrs. Davis & Jones, Camberwell, for blooms of their new varieties—Chas. Gibson, Mrs. Norman Davis, Miss Annie Lowe, and Edouard Audiguier—did not bring out any very meritorious specimens, Mr. Hawkins, Mr. Foot, and Mr. Limburn winning in their several classes. Amongst the miscellaneous exhibits not for competition, Messrs. W. & G. Drover showed six dozen splendid blooms of Japanese, incurved, reflexed, and

Anemones, and was awarded an extra prize. Mr. Groom also showed an excellent box of blooms, and Mr. Legg, nurseryman, Gosport, a fine effective group of Chrysanthemums and foliage plants. First class certificates were awarded to Messrs. W. & G. Drover for Japanese varieties Madame Baco and Avalanche; and to Mr. Agate, florist, for Japanese varieties, M. H. Cannell and Lady Lawrence.

MONMOUTH.—NOVEMBER 15TH AND 16TH.

THE third annual Exhibition of this Society was held in the spacious Rolls Hall. The exhibits of plants, blooms, also fruit and vegetables, surpassed both in number and quality anything of the sort seen in Monmouth before. So great was the demand for space that not only were the vestibule and corridor crowded with floral and vegetable products, but part of the stage and the gallery were called into requisition to enable exhibitors to display their entries.

The following is a list of the awards:—Group of Chrysanthemums, any varieties, arranged in a space equal to 100 square feet, first, J. M. Bannerman, Esq., Wyastone Leys (gardener, Mr. Powell). Second, George Tucker, Esq., The Shrubbery, Monmouth. Group of Chrysanthemums arranged in a space not exceeding 36 square feet. First, Rev. W. Watson, Monmouth. Second, Miss Panter, Whitechurch. Six trained specimens, first, J. M. Bannerman, Esq. For twenty-four cut blooms incurred, distinct varieties, G. H. Hadfield, Esq., Moraston House, Ross (gardener, Mr. W. Winnard), was a good first. For twelve incurred varieties, distinct, Canon Mapleton, Rocklands (gardener, Mr. R. Richardson), gained first honours, closely followed by C. L. Campbell, Esq., Glewston Court, Ross (gardener, Mr. S. T. Wright). For twenty-four Japanese, Canon Mapleton was a grand first, G. H. Hadfield, Esq., being second. For twelve Japanese, C. Palmer, Esq., Newlands, Glos., was first; C. L. Campbell, Esq., second. For twelve large Anemone varieties Canon Mapleton was first; Sir H. M. Jackson, Llantilio Court, Abergavenny, second. Canon Mapleton also had the premier award for twelve reflexed varieties. Foliage and flowering plants were well represented. For six single Zonal Pelargoniums, Colonel Walwyn, Crofty Viola, was first. Single stove plant in bloom, Canon Mapleton first. Three Orchids, distinct, J. M. Bannerman, Esq., was first; also for four foliage plants, six plants for dinner table decoration, and six stove or greenhouse Ferns, distinct. The fruit classes were keenly contested. C. Lee Campbell, Esq., was first in the following classes:—Collection of dessert fruit, six dishes; black Grapes, white Grapes; Pears, six distinct varieties; Apples, dessert, six dishes, distinct; Apple, dessert, one variety; Apples, culinary, three dishes; Apples, culinary, one dish; and for best collection of Apples. Vegetables were in strong force, the principal prizewinners being Messrs. Campbell, Leir, Palmer, Brown, Jackson, Hill, Allen, Vaughan, &c.—SOUTH WALES.

BERKHAMSTED.—NOVEMBER 16TH.

THE first Show of the above Society was held on Friday last in the Town Hall, and proved a thorough success as regards quantity and the numbers of exhibits, the hall being thronged with visitors during the afternoon and evening. The staging was ably carried out under the supervision of the President, Mr. F. Lane, and Mr. G. Beard, a very energetic Committeeman. The Hon. Secretary and Treasurer is Mr. A. B. Higgins.

In the open class for twenty-four incurred varieties, distinct, Mr. Brown, gardener to R. Henty, Esq., Abbots Langley, was first, his blooms being remarkably fresh and even throughout. For twenty-four Japanese the same exhibitor took premier honours, staging excellent blooms. In the classes open to members only for twenty-four Japanese, not less than eighteen varieties (Mr. Kirby, gardener), E. Mawley, Esq., Rose Bank, Berkhamsted, was to the fore with good blooms, having a very fine bloom of E. Molyneux. For twelve Japanese the competition was very keen between the first and second. Mr. Hicks, gardener to G. Pearson, Esq., Millfield House, Berkhamsted, was first with grand blooms; very fine were his examples of Thunberg, Soleil Levant, Baronne de Prailly, and Val d'Andorre. Mr. Kirby was second with fine blooms. The incurred in this division was the weakest part of the Show, the whole of the blooms being badly finished.

For a group of Chrysanthemums, not to exceed 40 feet, four competed. Mr. Higgins, gardener to A. G. Lucas, Esq., Ashlyns Hall, was easily first with a well arranged group and blooms of good quality, the only objection was too full a use of white stakes, a point that often goes very much against an exhibitor in a close competition. Second Mr. Flint, gardener to Mrs. Domens, Haresfoot, Berkhamsted, fairly well arranged, but poor in quality. For a miscellaneous group the first prize was deservedly awarded to Mr. Low, gardener to Earl Brownlow, Ashridge Park, Berkhamsted. This was one of the features of the Show, the whole being light, bright, and graceful. Second Mr. Higgins. Table plants was well and largely shown; for twelve Mr. Low was first with a good assortment. Fruit and vegetables was staged in quantity. For a collection of fruit Mr. Folkes, gardener to J. F. Halsey, Esq., M.P., was first with good black and white Grapes, Pears, Apples, a very fine dish of Late Duke Plums, and a Melon. Second Mr. Cameron, gardener to Hon. W. Ryder, Westbrook. Mr. Folkes was first with three bunches of Grapes. Second Mr. Tarbox, gardener to Lady S. Spencer, Berkhamsted. For a collection of twelve distinct dishes of vegetables Mr. Folkes was again first, being closely pressed by Mr. Exler, gardener to — Oxenden, Esq., Bovingdon House.

CUCKFIELD.

THE Cuckfield Chrysanthemum Society held their second successful show in the Talbot Assembly Rooms on the 20th and 21st inst., and was

fairly well patronised by the ladies and gentlemen in the neighbourhood, and during the evening the rooms were crowded. The entries were not quite so numerous as last year, but the quality, with few exceptions, was very good. The groups were seven in number, and were very creditable, five of the seven exhibitors making an effort at a better finish, so defective in those of last year. The premier award was given to Mr. H. Scutt, gardener to S. W. Erle, Esq., Mill Hall, with fresh well bloomed plants. Mr. J. Umpleby, gardener to H. Woodcock, Esq., Bolnere, Haywards Heath, was a very close second, with plants of superior growth, but the arrangement was a little too stiff to show them to advantage. Mr. A. Hillman, gardener to Mrs. Latham, Knowle, was third. Mr. Geo. Stringer, gardener to R. A. Bevan, Esq., Horsgate, fourth, and Mr. J. Mitchell, gardener to Mrs. Maberly, Mytten, was fifth with dwarf plants neatly arranged and well finished in front. Specimen plants were not numerous, Messrs. H. Scutt, J. Mitchell, and A. Hillman being the successful exhibitors. There was good competition in the class for six Primulus, Mr. R. Inglis, gardener to T. T. Cunliffe-Lister, Esq., Borde Hill, taking the first prize, and Mr. W. Manton, gardener to Mrs. Clifford Barrer, Pickwell Lodge, Bolney, the second prize. For six Cyclamens, Mr. T. Feist, gardener to F. M. Huth, Esq., Henmead Hall, was an easy first with good plants of a first-class strain.

Some local exhibitors have made a decided advance in growing cut blooms. Twelve incurred, Mr. T. Roberts, gardener to R. C. Nichols, Esq., Highby Manor, Balcombe, was first with large blooms of good substance. Back row—Jeanne d'Arc, Novelty, Mr. H. Morgan, Venus. Middle row—Lady Slade, Golden Empress, Mrs. Heale, John Salter. Front row—White Venus, Barbara, Eve, and Mabel Ward. Mr. J. Lingley, gardener to T. W. Best, Esq., Harvest Hill, was a good second. For twelve Japanese Mr. J. Lingley was first with the following, all very good:—Back row—Fair Maid of Guernsey, Madame C. Audiguer, Boule d'Or, Belle Paule. Middle row—Peter the Great, Meg Merrilies, Striatum, Baronne de Prailly. Front row—Val d'Andorre, Hiver Fleuri, Thunberg, M. Astorg. Mr. Roberts was second in this class. For twelve reflexed Mr. Roberts was first and Mr. Manton second, both showing well. There were only three entries for twenty-four blooms, half incurred and half Japanese, open to exhibitors within a radius of six miles, but those staged were of very good quality. Mr. T. Venn, gardener to W. Sturday, Esq., Paxhill, Lindfield, was first with fine large deep blooms. Incurred:—Back row—Jeanne d'Arc, Alfred Salter, Bronze Queen, and Golden Empress. Middle row—Emily Dale, Queen of England, Lord Alcester, and Princess of Wales. Front row—Jardin des Plantes, Cherub, Golden Queen of England, and Barbara. Japanese:—Back row—Mdle. Laeroix, E. Molyneux, Madame C. Audiguer, Fair Maid of Guernsey. Middle row—Marguerite Marrouche, Maiden's Blush, Val d'Andorre, and M. Bernard. Front row—Japonais, Hiver Fleuri, Peter the Great, and M. Astorg. Mr. F. Godby, gardener to Dr. Withers Moore, The Oaks, Burgess Hill, was second, and Mr. Roberts third. There was a spirited competition for a prize given for the best arranged vases of Chrysanthemums, open to the wives of members, amateurs, and cottagers. Mrs. J. Tugwell, Mrs. W. Sanders, and Mrs. Walter Ede won the prizes in the order named.

In the fruit classes for black Grapes, Mr. R. Inglis was first with Alicantes, Mr. T. Feist second with good Gros Colman. Mr. T. Roberts third with heavy Alicantes. Pears were but few, Mr. Stringer was first with splendid samples of Pitmaston Duchess and Marie Louise. He was also first for four dishes of Apples with fine clean fruit of Worcester Pearmain, King of Pippins, Warner's King, and Ecklinville. Messrs. J. Lingley, H. Scutt, and W. Manton followed in the order named. Mr. J. Lingley had undoubtedly the best dish in the room, Warner's King of remarkable size. The trays of vegetables were good, Mr. W. Manton carrying off the premier prize in his usual style; Mr. Stringer being a good second. There were several exhibits not for competition, the most conspicuous being a remarkably clean, even, and well coloured collection of twenty-four dishes of Apples and Pears, shown by Mr. Geo. Stringer, and they are a striking example of what can be done by a good cultivator on a very stiff Sussex clay, even in an adverse season. The arrangement of the exhibits was ably superintended by Mr. Umpleby.

LIVERPOOL.—NOVEMBER 20TH AND 21ST.

THE autumn Exhibition of this Society was held under equally unfavourable conditions as regards the weather as the spring and summer exhibitions. The Exhibition was held as usual in St. George's Hall, and was an excellent one and equalling those of previous years.

Cut blooms were as numerous as ever, but the quality was not quite up to the standard of excellence. The chief interest centred in the class for forty-eight blooms, thirty-six varieties, and not more than two blooms of any one variety, twenty-four to be incurred and the same number of Japanese. Five competitors staged blooms in this class, and the 10 guinea silver cup was deservedly awarded to Mr. J. Jellico, gardener to F. F. Gossage, Esq., Camp Hill, Woolton, who was thirty-three points ahead of Mr. F. Roberts, gardener to Mrs. W. D. Holt, Sandsfield Park, West Derby, who was also second, and Mr. A. R. Cox, gardener to W. H. Watts, Esq., Elm Hall, Wavertree, third with smaller, but neat flowers. The cup collection contained the following:—Incurred, back row—Queen of England, Lord Wolseley, Queen of England, Empress of India, Lord Wolseley, Lord Alcester, Alfred Salter, and Empress of India. Middle row—Prince Alfred, Golden Empress, Emily Dale, Prince Alfred, White Venus, Princess of Wales, Mrs. Heale, and John Salter. Front row—Alfred Salter, John Salter, Mrs. Shipman, Mr. Bunn, Princess Beatrice, White Beverley, Bronze Jardin des Plantes,

and Lady Hardinge. Japanese, back row—Boule d'Or, Belle Paule, Val d'Andorre, Ralph Brocklebank, Meg Merrilies, Val d'Andorre, Stanstead White, and Boule d'Or. Middle row—Avalanche, E. Molyneux, M. Tarin, Avalanche, Jeanne Délaux, Golden Meg Merrilies, Mdle. Paule Dutour, and E. Molyneux. Front row—Criterion, Elaine, Golden Dragon, Madame J. Laing, M. J. M. Pigny, Madame Baco, Stanstead White, and Charlotte de Montcabrier. For twenty-four incurved blooms, distinct, only two competitors staged blooms. Mr. G. Burden, gardener to G. Cockburn, Esq., was placed first, and Mr. D. Forbes, gardener to A. Holt, Esq., Crofton, Aigburth, second. The varieties in the first stand were:—Back row—Lord Alcester, John Salter, Empress of India, Alfred Salter, Emily Dale, Beauty, Golden Empress, and Queen of England. Middle row—Lord Wolsley, Mrs. Heale, Jardin des Plantes, Princess of Wales, Hero of Stoke Newington, Jeanne d'Arc, and Princess of Teck. Front row—Princess Beatrice, Charles Gibson, Nil Desperandum, Sir Stafford Carey, Mr. Bunn, Refulgens, Mrs. N. Davis, and Lady Hardinge. In the corresponding class for twenty-four Japanese the same exhibitor was again first with even bright coloured flowers. Of back row Golden Dragon, E. Molyneux, Madame C. Audiguer, Fair Maid of Guernsey, Criterion, Meg Merrilies, Marguerite Marrouch, and Boule d'Or. Middle row—Madame J. Laing, Pelican, Val d'Andorre, Ralph Brocklebank, Belle Paule, Jeanne Délaux, Madame J. M. Pigny, and M. Tarin. Front row—Elaine, Thunberg, Florence Perey, J. Laing, Martha Harding, Madame de Sevin, Soleil Levant, and Mrs. Cannell. Mr. J. Jellico was second, and Mr. R. Foster, gardener to H. Thompson, Esq., Thingwall Hall, Broad Green, third. For eighteen incurved, and the same number of Japanese, Mr. C. Osborne, gardener to H. J. Robinson, Esq., Aymestry Court, Woolton, was successful in both classes. Seven boxes were staged in the class for twelve incurved, and Mr. G. Butler, gardener to Thos. Drysdale, Esq., Moreus House, Mossley Hill, was well first. Mr. A. R. Cox and Mr. T. Foster, Green Bank, were second and third respectively. For twelve Japanese Mr. G. Butler was first amongst six competitors, and staged good flowers.

Both trained and untrained plants were shown in better condition than has been the case for two or three years past, the latter being far in advance of any previously staged. For four large flowered trained plants Mr. J. Hughes, gardener to H. Melver, Esq., was first with large fresh specimens, carrying very perfect blooms of John Salter, Jardin des Plantes, Mrs. G. Rundle, and Lady Hardinge. Mr. J. Harrison, gardener to Mrs. W. G. Bateson, New Heys, Allerton, was second with capital plants. For one plant the last-named exhibitor was first, and Mr. J. Hughes second. For four trained Pompons Mr. Harrison took the lead with grand examples of White Cedo Nulli, St. Michael, Maroon Model, and Lilac Cedo Nulli; Mr. J. Hughes and Mr. W. Bustard, gardener to J. Lewis, Esq., were second and third. For one Pompon Mr. J. Hughes was first. For one standard Mr. Harrison was first, and Mr. J. Hughes for one pyramid. For a group of plants Mr. J. Warrington was first, and Mr. H. Stone, gardener to H. Bennett, Esq., Weston House, second.

Stove and greenhouse plants were in some cases better than they have been on past occasions. For six the chief prizes were secured by Mr. A. R. Cox, Mr. J. Jellico, Mr. W. Bustard, Mr. T. Jones, gardener to W. C. Clark, Esq., Orleans House; Mr. T. Gowen, gardener to R. Brocklehurst, Esq.; Mr. J. Hurst, gardener to W. B. Bowring, Esq.; Mr. A. R. Smith, gardener to D. de Yarrondo, and Mr. C. Evans, gardener to W. Maxwell, Esq., Holmfild.

The display of Orchids was a slight improvement both in the quality and quantity of the exhibits. The prizes offered in the four classes were well contested, and the most successful exhibitors were Mr. C. Osborne; Mr. J. Edwards, gardener to H. Tate, Esq., Allerton Beeches; Mr. A. R. Smith; Mr. J. Madsley, gardener to W. C. Atkinson, Esq.; Mr. W. Wilson; Mr. J. Edward; Mr. J. McGrath, gardener to R. R. Heap, Esq., West Derby, and Mr. J. Bounds, gardener to A. L. Jones, Esq.

FRUIT.—The display of fruit was one of the best at any exhibition this autumn. No less than twenty classes were devoted to fruit, and every one of them was well filled. For twelve dishes, distinct, Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, won leading honours with good Queen and Smooth Cayenne Pines, excellent Muscat of Alexandria, Gros Colman, Golden Queen, and Alicante Grapes, Coe's Golden Drop Plums, a good Melon, Marie Louise and Pitmaston Duchesse Pears very fine, Blenheim Pippin and King of the Pippins Apples. Mr. J. Bennett, gardener to the Hon. C. H. Wynne, North Wales, was a close second; and Mr. J. Wallis, gardener to Ralph Sneyd, Esq., Keele Hall, third. For six dishes three collections were staged: Mr. T. Elsworthy, gardener to A. R. Gladstone, Esq., took the lead with remarkably fine Alicante and Golden Queen Grapes, Marie Louise and Louise Bonne de Jersey Pears, Best of All Melon, and Cox's Orange Pippin Apples; second, Mr. J. Bounds; third, Mr. E. Gregg, gardener to W. O. N. Shaw, Esq., Arrow Park, Birkenhead. Pines were large, and all the exhibits were of the first quality. For two fruits Mr. M. Geeson, gardener to the Duke of Newcastle, Clumber, Worksop, first; Mr. J. Elsworthy second; and Mr. G. Gibson, gardener to Mrs. Banks, Wigan, third. For one fruit the same exhibitor was again first, Mr. J. Bennett second, and Mr. G. Gibson third, the first prize fruit being particularly large.

For two bunches of black Grapes (Muscat flavour) no less than eight competitors staged against three last year. Mr. J. Ferguson, gardener to Mrs. Patterson, Rock Ferry, was first with Mrs. Pince in superb condition, Mr. J. Hollingsworth, gardener to J. F. Cambell, Esq., second, and Mr. A. Collins, gardener to S. Smith, Esq., M.P., Princess Park, third, both staging the same variety. For two bunches of Alicante no less than fifteen lots were staged, and every one worthy of a prize.

The post of honour was gained by Mr. T. Elsworthy with faultless examples, and the same may be said of those staged by Mr. Goodacre for the second award. Mr. J. Downham, gardener to E. H. Harrison, Esq., Eastham, third. For two bunches of black Grapes (any variety) fifteen exhibitors again staged. Mr. J. Ferguson was again ahead with large splendidly finished bunches of Gros Guillaume; Mr. A. Collins second with the same variety, and Mr. Goodacre third with Gros Colman, well coloured and very large berries. Some splendid Grapes had to be passed over in this class. For two bunches of Muscat of Alexandria Mr. G. Middleton, gardener to R. Pilkington, Esq., Rainford Hall, St. Helens, was first amongst nine exhibits. Er. D. Lindsay, gardener to Sir Thos. Edwardes Moss, Bart., Otterspool, second, and T. H. Rathbone, Esq., Alton Towers, Stoke-on-Trent, third. The first prize bunches were as near perfection as any we have seen staged. For two bunches any other white, Mr. A. Collins was first with Golden Queen; Mr. D. Lindsay and Mr. Elsworthy second and third respectively with the same kind. Eight lots were staged. For four bunches Mr. J. H. Goodacre took the lead with good examples of Lady Downe's, Alicante, Mrs. Pearson and Muscat of Alexandria; Mr. G. Middleton second, and Mr. J. Hollingsworth third. Six collections being staged. The Grapes throughout were decidedly more numerous and of much better appearance than we have ever before seen at this Society's Exhibition. Pears were not of average quality, and except the first and second collections in the class for eight dishes they need no particular comment, the classes were even better filled than usual. For eight dishes Mr. Goodacre was first with grand Beurré Diel, Beurré Boussoch, Beurré Bachelier, Louise Bonne de Jersey, Pitmaston Duchesse, Marie Louise, Beurré Hardy, and Duchesse d'Angoulême. Mr. W. Mease, Wyncote, Allerton, was second. For four dishes Mr. J. Kelly was first. For one dish Mr. Mease was first with Marie Louise. For six dishes of dessert Apples Mr. Goodacre was first with Nonesuch, Blenheim Pippin, Ribston Pippin, Astrachan, Cox's Pomona, and King of the Pippins. Mr. J. Davies, gardener to Rev. H. Arkwright, Bodenham, was second; and Mr. A. Williams, The Lawn, Bodenham, third. For three dishes, Mr. J. Bounds was well first amongst eleven competitors. For eight dishes culinary varieties, Mr. T. Davis was well first with very large fruit of Annie Elizabeth, Warner's King, Peasgood's Nonesuch, Ecklinville, New Hawthornden, Alfriston and Emperor Alexander. Mr. A. Williams second, and Mr. Goodacre third. For four dishes Mr. R. Pinnington, gardener to E. Bauner, Esq., was first.

Miscellaneous exhibits as usual were numerous and well worthy of notice, but we regret to say that the pressure on our columns compels us to pass over what added materially to the attractions of perhaps the finest Exhibition of the year.

LEEDS.—NOV. 20TH AND 21ST.

A SUCCESSFUL Exhibition was held on the dates named in the Leeds Town Hall. The severe frosts had reduced the number of specimen plants and groups, although sufficient were staged to make a creditable display. Cut blooms were contributed in good numbers and of average quality for the season. The Exhibition was opened by the Mayor, and it is to be hoped that the Society, which has had a chequered career, will on this occasion recoup itself financially, as the Committee have striven hard to make the shows a success. On this occasion the duties of Secretary were efficiently carried out by Mr. J. H. Clark; the staging arrangements were attended to efficiently by Mr. P. Featherstone, Chairman of Committee.

Cut blooms formed the most important part of the Exhibition, therefore merit notice first. The principal class was that for thirty-six distinct varieties, half to be Japanese and half incurved. Mr. T. B. Morton, Mowden Bridge Nurseries, Darlington, Durham, was easily first, his Japanese being heavy, well arranged, while the incurved were of good size but a trifle rough. The names were:—Japanese—Etoile de Lyon, Mdle. Lacroix, Belle Paule, Gloriosum, Mdle. Paule Dutour, Ralph Brocklebank, Holborn Beauty, La Triomphante, Boule d'Or, Mr. H. William, Criterion, Val d'Andorre, Stanstead White, M. Baco, Mdle. Louise Leroy, Edwin Molyneux, Avalanche, Meg Merrilies. Incurved—Queen of England, John Salter, Lord Alcester, Princess of Wales, Golden Queen of England, Empress of India, Lord Wolsley, Golden Empress, Jeanne d'Arc, Prince Alfred, Refulgens, Beverley, Sir Stafford Carey, Mr. Bunn, Mrs. Heale. Mr. Midgley, gardener to H. Mason, Esq., Bank-side, Bingley, was second, and had smaller flowers throughout. Third, Mr. H. Featherstone, Kirkstall, Leeds. For twenty-four distinct varieties, half incurved and half Japanese, there was only one entry, the first honours being awarded to Mr. T. Barclay, gardener to R. Clough, Esq., Keighley, the varieties being:—Japanese—Mdle. Lacroix, La Triomphante, Boule d'Or, Val d'Andorre, Criterion, Ralph Brocklebank, Baronne de Prailly, Madame C. Audiguer, Elaine, Sarah Owen, Jeanne Délaux, M. Freeman. Incurved—Nil Desperandum, Queen of England, Mr. Bunn, Empress of India, Beverley, Jeanne d'Arc, Refulgens, Lord Alcester, Prince of Wales, Princess of Wales, Mrs. W. Shipman, and Lord Wolsley. For twelve Japanese, distinct, Mr. Morton was first with a good stand of blooms, showing Etoile de Lyon, Belle Paule, Gloriosum, Edwin Molyneux, Le Sceptre Toulousain, Fair Maid of Guernsey, Mdle. Lacroix, Amy Furze, Meg Merrilies, Marguerite Marrouch, Ralph Brocklebank, and Stanstead White. Mr. Midgley second with smaller blooms.

Mr. Morton again took first honours for twelve incurved with medium-fresh blooms of Queen of England, Golden Queen of England, Salter, Jeanne d'Arc, John Salter, Empress of India, Princess of Lord Alcester, Golden Beverley, Lord Wolsley, Beverley, and

Mr. Bunn. Second, Mr. Barclay, with smaller blooms. Mr. Morton and Mr. Midgley again occupied first and second places for three Japanese, three incurved, three reflexed, and three large-flowered Anemones, both staging well. Mr. Morton staged the best Anemone-flowered in six distinct varieties. A special class was made by members of the Leeds Paxton Society for eighteen blooms, large-flowered distinct varieties. Mr. W. Grix, gardener to Sir James Kitson, Gledhow Hall, Leeds, was first with a good stand. Mr. W. Dury, gardener to Alderman Tyas, Barnsley, was second.

For a group of Chrysanthemums interspersed with foliage plants, space not to exceed 150 square feet, Mr. H. Featherstone occupied premier position with plants carrying large blossoms, well arranged, if we except the front, which exposed the pots rather too freely. The same exhibitor also occupied first place for a group composed exclusively of Chrysanthemums, except a front border of foliage plants, in 100 square feet, with freely flowered plants. For twelve specimens, six to be Japanese and six incurved, Mr. J. Eastwood, gardener to Mrs. Tetley, Leeds, was first with upright-trained plants with fairly good blooms, Mr. Featherstone second. The last-named was the principal prizetaker in other classes for plants of reflexed, Anemone Pompon, and single varieties with fairly good plants, as also was he first for six ornamental fine-foliage plants, bouquets, ladies' spray flowers, buttonhole bouquets, &c. Mr. Midgley took first prize for both black and white Grapes, two bunches each, with capital Muscat of Alexandria and Alicante, both well coloured. Much interest was centred in the dessert table, 8 feet by 4 feet, Chrysanthemums only, with any kind of foliage, to be used. Mrs. Rothery, Harrogate, was first with rather a heavy arrangement; Miss Battle, Moortown, second.

A first-class certificate was awarded to Mr. F. R. Hayes, gardener to J. E. Haggas, Esq., Keighley, for Chrysanthemum Miss M. A. Haggas, a pale yellow sport from Mrs. Heale, which retains the excellent qualities of its parent.

LINCOLN.—NOVEMBER 20TH AND 21ST.

THE sixth annual Exhibition was held in the Corn Exchange on the above dates, and the exhibits in all cases except specimen plants was superior to any in previous years. The Committee and Secretary (Mr. Pennell, jun.), are to be congratulated on the success of their efforts to make an Exhibition worthy of the city of Lincoln. The competition was exceeding close in the cut flower classes, groups of miscellaneous plants arranged for effect, dinner table decorations, and black Grapes. The spirit of emulation has been well developed at Lincoln, and the Society has amply justified its existence by having been the direct means of promoting a higher standard of culture of the queen of autumn flowers, and the development of a more artistic taste in the arrangement of plants in groups or otherwise by the leading gardeners of the neighbourhood. Lincoln this year has probably been unrivalled in the excellency of its groups, whether in competition or not for competition, and to Messrs. Herring, Mitchell, Wipf, Coulling, and Pennell & Sons belong the honour, the three latter contributing groups not for competition. The contest for the premier position in the prize list was between Mr. Herring and Mr. Mitchell, the former being adjudged the victor, but Mr. Mitchell was a very close second.

Miss Pennell maintained her usual position with dinner table decorations, and was placed equal first for an elegant arrangement in green and crimson, and Mr. C. Foster had a bright, graceful, pleasing arrangement, differing in character from Miss Pennell's, but equally good.

Black Grapes were well represented in all respects. Mr. Wipf led with moderate sized bunches and berries of Gros Maroc perfect in every respect, and Mr. Hare was a close second with excellent Alicante.

The following were the principal prizetakers:—Groups of Chrysanthemums and miscellaneous plants arranged for effect, first, A. Shuttleworth, Esq. (gardener, Mr. Herring); second, W. J. Warrener, Esq. (gardener, Mr. Mitchell); third, A. S. Leslie Melville, Esq. (gardener, Mr. Picker). Group of Chrysanthemums and foliage plants arranged for effect, first, T. C. Bourne, Esq.; second, T. Bell, Esq. (gardener, Mr. Dowman). Cut blooms, open to Lincolnshire and Nottinghamshire, twenty-four incurved, in eighteen distinct varieties, first, A. Shuttleworth, Esq.; second, W. J. Warrener, Esq.; third, Mrs. Oldman (gardener, Mr. Gill). Twenty-four Japanese, in not less than eighteen distinct varieties, first, A. Shuttleworth, Esq.; second, Mrs. Oldman; third, W. J. Warrener, Esq. Eighteen blooms, six incurved, six Japanese, and six reflexed, first, T. C. Bourne, Esq. (gardener, Mr. Brown); second, Mr. E. Beevers; third, T. Bell, Esq. In other cut bloom classes the chief prizes were won by Messrs. J. J. Burt, C. E. Marfleet, A. Shuttleworth, and Mrs. Oldman.

YEOVIL.—NOVEMBER 21ST.

THIS Show, which was allowed to lapse last year, was held in the Town Hall, under, it may be said, new management, on the above date, and the Committee and courteous Hon. Secretary (Mr. W. B. Milborne) deserve great credit for coming forward to prevent the Yeovil Chrysanthemum, Fruit and Flower Show Society becoming a thing of the past, and they are to be congratulated upon the success and excellence of the Show resulting from their labours, and the support extended to them by the citizens of the town and the district.

Seven capital groups were arranged, two composed of Chrysanthemums, the remainder being made up of miscellaneous plants. Mr. Crossman, gardener to J. Brutton, Esq., was first in the former

class, and Mr. S. Kidley, gardener to H. A. Helyer, Esq., Coker Court, Yeovil, occupied a like position in the latter class. The plants staged in the several classes provided for Chrysanthemums call for no special remark further than saying there is plenty of room for improvement in their culture. Table plants were well shown by Mr. Channon, gardener to Mrs. Harbin, Newton House, Yeovil; Mr. Lloyd, gardener to Vincent Stuckey, Esq., Langport; and Mr. C. Bowers, gardener to T. Holford, Esq., Castle Hill, Cerne. Mr. C. Anthony, gardener to T. Moore, Esq., Yeovil, had the best six Primulas, showing large well flowered plants of the old Double White in fine condition.

Although the competition in the cut bloom classes was not so keen as might have been expected, owing no doubt to the Bristol Show being held the same day, the quality of the exhibits in the winning stands was excellent. Mr. C. Lucas, gardener to John Marshall, Esq., Taunton, was a capital first for a stand of twenty-four blooms, distinct, with Japanese Baronne de Prailly, Criterion, Mrs. J. Wright, Ralph Brocklebank, Comte de Germiny, Duchess of Albany, Fair Maid of Guernsey, M. Elliott, Boule d'Or, Madame C. Audiguier, Japonais; incurved, Empress of India, Prince of Wales, Mrs. Norman Davis, Jeanne d'Arc, Golden Empress, Bronze Queen, Queen of England, Princess of Wales, Lord Wolseley, Jardin des Plantes, Emily Dale, and Lord Alcester. The flowers throughout this stand were large, solid, even, and fresh. The same exhibitor had the best stand of twelve reflexed blooms. Mr. W. Cocks, gardener to W. Fitzherbert Wyndham, Esq., Kingswear, South Devon, had the best stands of six Japanese and six incurved.

There was a good display of fruit, and the quality generally was good. There were only two collections of six kinds staged. Mr. Lloyd was a good first, showing Black Alicante and Trebbiano Grapes, Glou Morceau Pear, Ribston Pippin Apples, Nottingham Medlars, and Vicomtesse Hericart de Thury Strawberry. Mr. Crossman, gardener to J. Brutton, Esq., was second. Mr. Lloyd was also first for two bunches of Alicante, showing large and fairly well coloured bunches, first for two bunches of any other black with good bunches of Mrs. Pince of fairly good colour. Mr. G. R. Daley, gardener to R. Stainer Randle, Esq., Maperton House, Wincanton, was first for two bunches of Foster's Seedling, in the any other white Grape class, and Mr. Crossman was first for white Muscats. Mr. Hobby, gardener to the Hon. Sir Ponsonby Fane, Brympton House, Yeovil, showed two neat well coloured bunches of Black Hamburgh in the any other black than Alicante class, which secured for him second prize. Pears and Apples were shown well by Mr. Lloyd and Mr. Daley.

Mr. Scott of Yeovil and Messrs. Veitch & Son of Exeter staged two meritorious collections of Apples, not for competition, the former consisting of sixty-two dishes, and the latter forty-eight dishes.

Vegetables were shown well. There were four collections of eight kinds, and three collections of six kinds of salading, capitally set up. Mr. Bowers was first in both classes with capital produce, the Leeks, Onions (Rusham Park Hero), Sutton's Eclipse Cauliflower, Intermediate Carrot, Golden Gem Turnip, and Sutton's Seedling Potatoes being his best dishes.

CROYDON.—NOVEMBER 21ST.

THE newly constituted borough of Croydon Chrysanthemum Society held their first Exhibition at the Skating Rink Hall on Wednesday last, which was opened by the Mayor of Croydon. The Old Croydon Horticultural Society this year decided for one of the best of reasons, want of funds, to discontinue their annual Chrysanthemum Show, and a goodly number of gardeners and lovers of the Autumn Queen in the locality formed the new Society, and if their first Exhibition is any criterion of their future success there is little doubt but what they will hold their own with ease. The Skating Rink was filled with exhibits to the utmost extent—flowers, plants, foliage, fruit, and vegetables were of excellent quality, the arrangements were admirable, and great credit is due to the Hon. Secs., Mr. W. B. Beckett and Mr. G. L. Brown, and the Committee.

In the open class for a group not exceeding 50 square feet, Mr. W. Curd, Lower Addiscombe Road, was first with an exceedingly well arranged group containing blooms of fine quality. Mr. Sewell, of Sydenham Road, Croydon, was second. Mr. King, gardener to P. Crowley, Esq., Waddon House, secured first honours both for twenty-four incurved and twenty-four Japanese blooms. The other prizewinners in the open classes were J. Brown, Reigate; T. Pannell, C. Symmons, F. Willshire, and J. Rodburn.

The local classes for gardeners and amateurs were well filled. Mr. W. Jupp, gardener to C. Johnson, Esq., was first for twenty-four incurved blooms of good quality, closely followed by C. Welstead, second, and C. Stew, third. For twenty-four Japanese J. Redburn first, and C. Stew second. In the class for six incurved blooms, one variety, Mr. G. Lane led the way with well finished flowers of Lord Alcester. The same exhibitor was first in the class for six Japanese with massive blooms of Madame C. Audiguier. Other prizewinners in these classes were W. Jupp, C. Evans, and W. Tomlinson. The open amateur and single-handed gardeners' classes made a fine display both of blooms and vegetables, and amongst the prizewinners were Messrs. J. Staines, Jones, C. Welstead, C. Perratt, and J. Wood and H. W. Davis. For three dishes of Pears those exhibited by the Rev. W. Wilks were very fine and also first, Mr. H. W. Davis second, and Mr. C. Perrett third. The lady subscribers contributed some handsome centerpieces for tables, amongst them being Mrs. Fewell, Miss Burnham, and Mrs. Beckett.

Amongst the miscellaneous exhibits not for competition were six boards of grand blooms staged by Mr. C. Gibson, gardener to C. Wormald,

Esq., Morden Park, Mitcham. The most conspicuous in his board of Japanese were Ralph Brocklebank, Lady Lawrence, and Meg Merrilies. His incurved flowers were of superior quality, and contained Princess Beatrice, Princess of Wales, and Lord Alcester. In his stand of Japanese Anemone an enormous flower of Madame Cabrol was staged. This collection also included two boards of both Anemone and reflexed Pompons. Mr. Butcher of Sydenham Road put up a very attractive group of foliage and Chrysanthemum plants on the platform; some well trained plants were also exhibited by the same grower and awarded a special prize. Messrs. J. Laing of Forest Hill had a good group of Palms and Chrysanthemums, including many of the new varieties; amongst them we noticed Etoile de Lyon and Sarah Owen. Messrs. Bunyard of Maidstone staged a fine collection, 100 dishes of Apples. The exhibit of Messrs. Cannell & Sons of Swanley, which comprised bunches of Chrysanthemums and a fine exhibit of Zonals, were a great attraction to the visitors. Mr. Cheal of Crawley also exhibited a fine collection of fruit, and a very fine and instructive display was contributed by A. H. Smee, Esq., Hackbridge (gardener, Mr. G. Cummins), the most useful varieties for succession being indicated.

RUGBY.—NOVEMBER 21ST AND 22ND.

THE second Show of the Rugby and District Chrysanthemum Society was held in the Town Hall on the above dates, and proved most satisfactory in all respects, the exhibits being numerous, of capital quality, and the attendance of visitors good. The Hon. Secretary, Mr. W. Bryant, assisted by a practical Committee, has already secured an exhibition of considerable interest, and with adequate local support will soon develop into one of still more importance, as it is evident there are plenty of good cultivators in the district.

The cut blooms were notable throughout the principal classes for their neatness, and the competition was extremely close in several classes. This was especially the case in the class for thirty-six blooms, distinct varieties, eighteen incurved and eighteen Japanese, in which there were five competitors, the blooms from three of these being so nearly equal that they had to be most carefully "pointed," with the result that there were only four points difference between them, the first leading by three, and the second was only one point ahead of the third. The first prize (£2 10s.), together with a special prize of equal value contributed by Mr. W. Bryant, was won by Mr. H. Dunkley, gardener to S. Symington, Esq., Brookland House, Market Harborough, who had the following varieties well represented, the incurved and Japanese nearly equal in merit. Incurved: Back row—Queen of England, Guernsey Nugget, Lord Alcester, Golden Empress, Empress Eugénie, and Empress of India. Middle row—Prince Alfred, Princess of Wales, Jardin des Plantes, Cherub, Beverley, and Lord Wolseley. Front row—Jeanne d'Arc, Mr. Brunlees, Venus, Barbara, Baron Beust, and Mabel Ward. Japanese:—Back row; Ralph Brocklebank, Edwin Molyneux, Madame B. Pigny, Baronne de Prailly, Japonaise, and Meg Merrilies. Middle row—Mrs. J. Wright, Duchess of Albany, Madame C. Audiguier, Criterion, Belle Paule, and Thunberg. Front row—Boule d'Or, Dr. Macary, Golden Dragon, Elaine, Val d'Andorre, and Fair Maid of Guernsey. Mr. W. Comfort, gardener to G. A. Everitt, Esq., Knowle Hall, was second, his Japanese blooms being much superior to his incurved, which was also the case in the third prize collection from Mr. J. Morris, gardener to Sir R. Moon, Bart., Copswood Grange, Coventry.

With twelve incurved blooms, distinct varieties, there were also five exhibitors, who contributed blooms very close in merit, and the premier honours were again secured by Mr. Dunkley, who had compact solid examples of the following varieties:—Back row—Lord Alcester, Golden Empress, Queen of England. Middle row—Jardin des Plantes, Princess of Wales, Prince Alfred, and Empress of India. Front row—Baron Beust, Mabel Ward, Lord Eversley, and Venus. Messrs. Morris and Comfort followed as second and third respectively. Amongst four competitors in the class for twelve Japanese, Mr. Comfort won the first place with fresh and excellent blooms of Boule d'Or, Comtesse de Beauregarde, Ralph Brocklebank, Madame C. Audiguier. Middle row—Meg Merrilies, Marguerite Marrouch, Madame Baco, and Fair Maid of Guernsey. Front row—Criterion, Mdle. Lacroix, Madame J. Laing, and Val d'Andorre. Mr. Morris was second, and Mrs. Caldicott, The Lodge, Rugby (gardener, Mr. B. Robinson), was third.

In the classes for groups of Chrysanthemums several admirable contributions were staged, notably those from the Rev. F. D. Moore, Hillmorton Road, Rugby (gardener, Mr. J. Morton), and W. G. Mitchell, Esq., Church Walk, Rugby (gardener, Mr. G. W. Batehelor), who were awarded the premier prizes in two classes. The Rev. J. W. Vaequeray, Hillbrow, Rugby (gardener, Mr. Durbin), and Mr. J. Parker, Rugby, also exhibited well. Fruits, especially Apples and Pears, were well shown, as also were vegetables, the competition being exceedingly keen in all these classes. Mr. G. Goldsmith, gardener to Sir E. G. Loder, Bart., Floore, Weedon, gained leading honours for dessert and kitchen Apples, Pears, and a collection of vegetables with capital specimens in every case, showing good culture.

Several non-competing groups were exhibited, but an extensive and handsome display of plants from Mr. Parker was greatly admired. Mr. Bester also had a neat group.

BIRMINGHAM.—NOVEMBER 21ST AND 22ND.

THE Birmingham and Midland Counties Chrysanthemum Society is not young, but possesses all the vigour of youth, while the ripe experience of its officials enables them to conduct the exhibitions in the most

satisfactory manner. The prize cards are the best we have seen, the names of the owners of the exhibits and their gardeners, with the number and description of the classes, being clearly printed on them; not a line is written on the cards, so there can be small excuse for mistakes in transcribing. The class and exhibitor's numbers are on the back of the cards, as is customary at most shows, but at Birmingham the cards have only to be turned over and the awards stamped on, all particulars being then "in print," hence easily read by a moving mass of visitors, a matter of importance in a crowded show where obstruction is often caused by the delay consequent on attempts to decipher hurriedly written names. The Judges' cards are also simple and effective.

Birmingham shows have long been celebrated for specimen plants, and latterly the groups have been of a high order of merit. In these the improvement has been very great, but not more marked than in the cut bloom classes. A few years ago these were comparatively weak, but now they are strong, and it is questionable if finer stands have been seen in competition this year than those of Messrs. Parker and Lindsay, the former, however, distinctly taking the lead; indeed, the cut blooms were the most important feature of the Exhibition, and plants were for once put in the shade, so to say, at Birmingham, a no small feat to achieve, and might, perhaps, not have been accomplished if the specimens of the great grower, Mr. W. H. Dyer, had not been ruined by the early and severe October frost. Do not let it be supposed, however, that there were no plants worth seeing; on the contrary, there was really a rich display in the body of the handsome Town Hall, Mr. E. Cooper, gardener to the Right Hon. Joseph Chamberlain, exhibiting well and taking the chief prizes, a good share of honours also falling to Mr. O. Brazier, gardener to Sir Thomas Martineau, Elgbaston, and Mr. F. Cooper, gardener to C. Showell, Esq. Mr. E. Cooper also secured the first prize with one of the best groups we have seen during the season, Messrs. A. Cryer, gardener to J. A. Renriek, Esq., and J. Walshall, gardener to J. B. Lees, Esq., following. Messrs. Wood & Son's medal for three plants was won by Mr. E. Cooper. And now, through want of space, the plants must be dismissed in order that the blooms in this, the twenty-fourth Show of the Society, may be noticed in the leading open classes.

Primary interest naturally centred in the great class of forty-eight blooms, distinct, half incurved and half Japanese, the prizes offered being £10, £7, £4, and £2. There were four competitors, the first prize falling, as previously indicated, to Mr. R. Parker, gardener to J. Corbett, Esq., M.P., Impney, Droitwich, who has in a very short time won his way into the front rank in the Chrysanthemum world. The incurved blooms were not only well grown but well finished, not large and loose, but of good size and firm, while the Japanese were large, full, and fresh. The varieties were as follows:—Incurved—Back row—Alfred Salter, Empress of India, Lord Wolseley, Emily Dale, Queen of England, Golden Empress, Lord Alcester, and Prince Alfred. Middle row—Refulgens, Jeanne d'Arc, Mrs. Heale, Hero of Stoke Newington, John Salter, Princess of Wales, Nil Desperandum, and Jardin des Plantes. Front row—Lord Eversley, Lady Carey, Barbara, Princess of Teck, Charles Gibson, Cherub, Mrs. N. Davis, and Mr. Brunlees. Japanese:—Front row—E. Molyneux, Ralph Brocklebank, Avalanche, Mdme. C. Audiguier, Meg Merrilies, Boule d'Or, Baron de Prailly, and Carew Underwood. Second row—M. J. Pigny, Duchess of Albany, Thunberg, Mrs. H. Cannell, Val d'Andorre, Fair Maid of Guernsey, M. J. Laing, and Mdle. Lacroix. Front row—J. Délaux, M. Freeman, Marguerite Marrouch, Criterion, Mr. H. Cannell, M. Brunet, Martha Harding, and Comte de Germiny. Mr. D. Lindsay, gardener to Sir T. Edwardes-Moss, Bart., Otterspool, staged remarkably well, but was not quite equal in either section to his successful rival, though he had no great difficulty in winning the second place. Some of his blooms were a little past their best, but very fine indeed were Queen of England, Empress of India, Mrs. Heale, Princess of Wales, Boule d'Or, Criterion, and Belle Paule. Mr. A. Haggart, gardener to Mrs. Foster, Ludlow, followed, the remaining prizetaker being Mr. E. West, gardener to H. Wright, Esq., both having creditable stands of blooms.

Mr. Parker was also well ahead of his rivals in the class of twenty-four blooms, distinct, twelve incurved and the same number of Japanese, staging admirably in the former section Lord Wolseley, Queen of England, Emily Dale, Golden Empress, Lord Alcester, Empress of India, Alfred Salter, Princess of Wales, Mrs. Heale, Princess Teck, Jeanne d'Arc, and Barbara; and in the latter, Ralph Brocklebank, Fair Maid of Guernsey, Boule d'Or, Meg Merrilies, M. Brunet, E. Molyneux, Avalanche, Baron de Prailly, Criterion, M. J. Laing, Mr. H. Cannell, and M. Freeman, Messrs. Walshall and Haggart following in the order named with good examples of culture. Mr. Lindsay won the chief position with eighteen incurved blooms, distinct, with excellent examples of Empress of India, Lord Wolseley, Emily Dale, Prince Alfred, Lord Alcester, Queen of England, John Salter, Mrs. Heale, Princess of Wales, Mr. Bunn, Alfred Salter, Golden Empress, Jardin des Plantes, Princess Beatrice, White Venus, Sir S. Carey, White Beverley, and Mr. Brunlees. Mr. Haggart was second, his best blooms being Alfred Salter, Lord Wolseley, Lord Alcester and Queen of England, Mr. E. West following very closely with the third prize.

In the open class of twelve Japanese blooms, distinct, Messrs. Parker and Lindsay came into competition again, the former securing the foremost place with a beautiful stand, comprising Meg Merrilies, Boule d'Or, Avalanche, Madame C. Audiguier, J. Délaux, Baronne de Prailly, E. Molyneux, Ralph Brocklebank, Mrs. H. Cannell, Duchess of Albany, Mdle. Lacroix, and M. J. Laing. Mr. Lindsay was second, and Mr.

T. Lambert, gardener to Lord Harlech, a very good third. Excellent competition and good stands were observable in the local classes, the chief prizewinners being Messrs. W. H. Dyer, O. Brasier, J. Steeley, and W. Clements.

Primulas are always a great feature at Birmingham, the best display probably to be seen at any show in the kingdom. Messrs. J. B. Thomson, Pope and Son, and E. Cooper were the prizetakers in the open classes, Mr. W. H. Dyer taking the lead in the local gardeners' and amateurs' section. Mr. Chamberlain's Orchids were much admired, as were the plants of Mr. Winn that received the first prize in the class provided for them. Bouquets were numerous and good, Messrs. Perkins and Pope and Sons taking the prizes in the nurserymen's class, and Messrs. Morgan, James, and Fowkes in the gardeners' class, who had to prepare their exhibits in the hall on the morning of the Show.

Fruit was well staged, but we can say that Messrs. Pratt, Goodacre, and Lindsay were the leading prizewinners in the Grape classes, Mr. Gleeson with Pines, and Messrs. Goodacre and Parker with Apples and Pears respectively. Messrs. T. Rivers & Son, Sawbridgeworth, had a fine collection of Apples and Pears, which was granted a certificate of merit. Mr. John Crauston, King's Acre, Hereford, exhibited a good collection of Apples and Pears, containing many good varieties of sterling merit. Messrs. Richard Smith & Co., Worcester, also contributed an extensive collection of fruit, which attracted a considerable amount of attention from visitors.

Amongst miscellaneous exhibits that contributed to the beauty and interest of the Exhibition were Cyclamens from Messrs. Sutton & Sons, Reading, a fine strain, the plants not yet twelve months from the seed pan, being crowded with flowers. Several of the varieties were awarded certificates—namely, Queen of Dwarfs, Delicatum roseum, Marginatum, Vulcan (a grand dark colour), Giant White, and Persicum roseum. Messrs. Hans Niemand & Co. had a beautiful stand of flowers made up into sprays, buttonholes, and other ornaments for personal adornment. In the centre of their stand was a charming basket of flowers for a birthday present, and at the back of the stand a little raised above the rest were four oval mirrors encircled with flowers and foliage to represent the four seasons—spring, summer, autumn, and winter, a novel idea well carried out. The same firm also exhibited a large group of ornamental foliage and flowering plants for decorative purposes. An on-looker remarked he did not think Birmingham would be Birmingham without Mr. Spinks and his decorations. Messrs. Thomson & Sons, Sparkhill, also contributed a fine group of flowers and foliage plants, such as Roman Hyacinths, Poinsettias, Bouvardias, Chrysanthemums, Primulas, &c., tastefully arranged. At the side of their group was an enormous wreath composed of the choicest flowers. The Covent Garden value of this wreath was estimated by an expert at not less than 10 guineas. Messrs. Perkins & Sons of Coventry had a stand of choice floral designs. Messrs. Hewitt & Co., Solihull, also contributed a large wreath of white flowers and an attractive group of plants. Messrs. Pope & Son also showed a similar group, amongst which were some especially fine Zonal Pelargoniums, very bright and cheerful. Mr. Robert Owen, Maidenhead, showed some stands of new Chrysanthemums, including Sunflower, 8 inches in diameter; George McLure, equally large, rosy pink; and a yellow sport from M. J. Laing.

It will be perceived from the above sketch that the Show was both great and varied, a credit to the town, society, exhibitors, and officials.

BRISTOL.—NOVEMBER 21ST AND 22ND.

THIS was a decided success in every way, and the best Exhibition yet held in Bristol. The Society has been established exactly a quarter of a century, and it is very satisfactory to find that in spite of the numerous societies recently started in the vicinity it is yet able to more than hold its own. Of late years the shows have been held in the Clifton Drill Hall, and this commodious structure was none too large for the display. Mr. F. Wilford Jones is a very efficient Secretary, and the Committee is composed of practical gardeners, but the arrangements were by no means perfect. Some idea will be formed of the extent of the Show when it is stated that there were about four hundred entries sent in by as many as seventy competitors.

A six-guinea eup was offered as the first prize for six trained large flowered varieties, but this failed to attract fresh competitors. It was awarded to Mr. J. Lee, gardener to S. M. Miller Esq., who had neatly trained well flowered specimens. Mr. J. Ayres, gardener to T. M. Gibson, Esq., was a good second. The third prize was won by Mr. M. Cole, gardener to W. F. Tredwell, Esq., Bath, and Mr. A. Ambrose, gardener to G. A. Tilney, Esq., was highly commended. The last named was well first for six Japanese varieties, among these being freely flowered specimens of Fair Maid of Guernsey, Peter the Great, and Mdle. Melaine Fabre. Standards of large flowered varieties were shown by Mr. M. Cole. The classes for single specimens were not so well filled. Mr. J. Lee was first for four Pompons, and Mr. H. Lewis, gardener to Boddam Castle, Esq., second. Mr. E. T. Hill was the only exhibitor of naturally grown. There were six groups to occupy a space 12 feet by 7 feet in competition, and not a poor one among them. The first prize was awarded to Mr. A. Parkes, gardener to Captain Alcock, who had a fine bank of plants with large fresh blooms in good variety, a row of dwarf plants giving a good finish to the arrangement. Mr. A. Ambrose was second; Mr. W. Coates, gardener to Mrs. Miller, third; and an extra prize was given to Mr. J. Marshall, gardener to J. Dob, Esq., all having very creditable displays.

Miscellaneous plants are much needed in such a large hall, and

numerous prizes were offered for them accordingly. Groups to occupy a space 10 feet by 5 feet were shown by six competitors, and a very imposing display was made. Mr. W. Coates was well first, his arrangement being full, light, and tasteful. Mr. J. Lee was a good second; Mr. J. Goddard, gardener to R. Cripps, Esq., third, and an extra prize was awarded to Mr. A. Parkes. In addition to these Messrs. J. Garaway and Co., Durdham Down Nurseries, Clifton, also had a group of choice flowering and fine-foliaged plants, but not for competition. In other plant classes the prizetakers were Mr. E. Miller, gardener to F. Tagart, Esq., Mr. F. Edwards, gardener to J. Lysaght, Esq., Mr. G. Harris, gardener at the Bristol Zoological Gardens, Mr. A. Hancock, gardener to A. W. Summers, Esq., Mr. J. Lee, Mr. G. Price, gardener to S. Budgett, Esq., Mr. W. H. Bannister, gardener to H. St. Vincent Ames, Esq., Mr. W. J. Cole, gardener to Mrs. Oldland, Mr. J. Shelton, gardener to W. R. Wait, Esq., and Mr. J. Harris, gardener to W. C. Trotman, Esq.

CUT BLOOMS.—This year no fault could be found with either the value or number of prizes offered for cut blooms, and as a consequence the competition was much better than at any previous show in Bristol. The premier prize, a silver cup value six guineas, was offered for thirty-six blooms large flowered Chrysanthemum, twenty-four incurred in not less than eighteen distinct varieties, and twelve Japanese distinct, and for this there were six competitors. After a careful scrutiny the Judges awarded the first prize to Mr. W. Thomas, gardener to W. Marshall, Esq., Taunton, who was very strong with the Japanese, and had many fine blooms among the incurred varieties. The latter consisted of Mrs. Heale, Empress of India (2), Hero of Stoke Newington, Lord Alcester, Bronze Queen of England, Cherub, Princess Alice, Lord Wolseley, Emily Dale, Empress Eugénie (2), Mrs. Norman Davis, Jeanne d'Arc, Prince Alfred (2), Jardin des Plantes (2), Eve, Refulgence, Antonelli, and Barbara. The Japanese comprised Boule d'Or, W. G. Drover, E. Molyneux, Baronne de Prailly, Meg Merrilies, Thunberg, J. H. Laing, Duchess of Albany, Val d'Andorre, Belle Paule, J. M. Pigny, and Fair Maid of Guernsey. Mr. A. Parkes, who took the second prize, had many fine blooms of incurred varieties, notably of the Queen family, but lost ground with the Japanese. The third prize was awarded to Mr. E. Miller, who had good even blooms, and all the other competitors had very creditable stands of blooms. There were seven entries with twelve incurred varieties, the first prize being well won by Mr. C. Cooper, gardener to C. L. Collard, Esq., Taunton, who had massive blooms of Empress of India, Prince Alfred, Golden Empress, Lord Wolseley, Alfred Salter, Jeanne d'Arc, Lord Alcester, Princess of Wales, Refulgence, Jardin des Plantes, Lady Hardinge, and Barbara. Mr. W. Carpenter, gardener to A. Cole, Esq., was a good second, and Mr. W. J. Cole, gardener to Mrs. Oldlands, third. The best six incurred blooms were shown by Mr. A. Parkes. Anemone flowered varieties were not largely shown. For a stand of twelve blooms in not less than six distinct varieties Mr. C. Lucas was well first, having fine blooms of Madame Cabrol, Lady Margaret (2), Fabian de Mediana, Duchess of Edinburgh, Acquisition (2), Georges Sand, Timbale d'Argent, Minnie Chate, Fleur de Marie (2), and Gluck.

Japanese varieties were well shown. The first prize for eighteen distinct varieties was awarded to Mr. C. Cooper, who had fine fresh bloom of Fair Maid of Guernsey, Boule d'Or, Val d'Andorre, E. Molyneux, Baronne de Prailly, Comte de Germiny, Forester, Japonais, Belle Paule, Carew Underwood, Mr. J. Pigny, Maiden's Blush, Thunberg, Madame J. Laing, Madame C. Audiguer, Ralph Brocklebank, and J. Délaux. Mr. W. Thomas was a close second, and G. Runnacles, gardener to C. Thurburn, Esq., Sherborne, third. Mr. Davis was well first for twelve varieties, these consisting of Madame C. Audiguer, E. Molyneux, Baronne de Prailly, Boule d'Or, M. J. Pigny, Belle Paule, Japonaise, Fair Maid of Guernsey, Val d'Andorre, Thunberg, Madame J. Laing, and J. Délaux. Mr. W. Carpenter was second, and Mr. C. Lucas third. Mr. J. Applin (gardener to W. M. Baker, Esq., Gloucester) was first for six blooms. A prize was offered for six blooms of incurred varieties sent out in 1886, 1887 and 1888, and this was won by Mr. E. Miller, who had Bronze Queen of England and Mrs. Norman Davis fairly good. The same exhibitor was first in a corresponding class for Japanese varieties. The competition with hand bouquets in the open class was very close, a remarkably choice selection of flowers being used in each in each instance.

FRUIT.—There was a very marked increase of entries in this section, and a fine display was made. Four competed with a collection of six dishes of fruit. Mr. W. Iggulden, gardener to the Earl of Cork, Frome, was first, being closely followed by Mr. W. Coates, the third prize going to Mr. W. Bannister. There were six entries in the class for Black Hamburg Grapes, Mr. Bannister was first. A similar number staged Muscat of Alexandria. Mr. W. Coates was first for beautifully finished bunches; Mr. J. Gibson, gardener to Earl Cowley, second; and Mr. J. F. Wilkinson, Gloucester, third. Sixteen competed with Alicante, the lead being taken by Mr. W. Iggulden, who had large well finished bunches, and was closely followed by Mr. E. T. Crocker, gardener to Mr. W. H. Miles; the third prize going to Mr. T. Jones, Bath. Nine entered the class for Lady Downe's, Mr. E. T. Crocker being well first with fine bunches a foot long. The same number competed with Gros Colman. Mr. W. Iggulden was first with massive well-coloured bunches. One exhibitor staged two bunches which together weighed upwards of 11 lbs., but they were not well coloured. Mr. J. F. Wilkinson was first for Mrs. Pince. In the class for any other black variety Mr. E. T. Crocker was first with very good Gros Maroe. A corresponding class was provided for white varieties, and in this Mr. J. T. Wilkinson was first with large well-coloured Raisin de Calabrie. Pears and

Apples were numerous shown, and the quality good. Mr. Bannister was most successful with the former, other prizewinners being Messrs. Iggulden, Pragnell, H. Ricketts, and J. Lee. The first prize collection of six varieties of dessert Apples, staged by Messrs. Cranston & Co. were worthy of special mention. These consisted of exceptionally good dishes of Egremont Russet, Gravenstein, King of the Pippins, Cornish Aromatic, Baumann's Reinette, and Ribston Pippin. Messrs. Pragnell, Iggulden, Goddard, Payne, Aplin, and E. T. Hill were also prizewinners in the various classes for Apples. Messrs. Cranston & Co. staged a very good collection of Apples not for competition.

VEGETABLES.—Two classes for collections were provided, and in both the competition was close. The first prize for ten distinct varieties was awarded to Mr. W. Banuister. Mr. W. G. Pragnell had rather finer produce, but not so fresh as those which received the preference. Mr. J. H. Virgo was a good third, and also first in another class, in which Messrs. Sutton & Sons provided the prizes; Mr. Goddard was second, and Mr. E. T. Hill third.

NOTTINGHAM.—NOVEMBER 21ST AND 22ND.

A SHOW of Chrysanthemums, Fruit and Potatoes was held on Wednesday and Thursday, November 21st and 22nd, in the Arboretum Rooms, Nottingham, and in every respect the Show was admitted to be amongst the best the Society has yet held. Although the general public failed to attend, a large number of members and others interested were present. A fairly liberal schedule of prizes was issued, and the entries in the various classes were numerous. Groups of Chrysanthemums with foliage and other plants arranged for effect on space 12 by 8 feet, occupied the ground floor. E. W. Field, Esq., Aspley Hall (gardener, Mr. Wilson), easily obtaining first honour with a beautifully, evenly balanced group of dwarf Chrysanthemums (principally Japanese), carrying brightly coloured flowers intermixed with Palms, Crotons, Pandanus, Dracenas, Cyrtipediums, and other dwarf plants, Adiantums and the pretty *Eulalia japonica* forming the groundwork. W. H. Farmer, Esq. (gardener, Mr. Attenboro), was a good second, and Mr. C. J. Mee, Wollaton Hall, secured third honours.

In the class for twelve cut blooms, Japanese, Mr. Wilson was again successful in obtaining first honours with magnificent examples of Coquette de Castile, Soleil Levant, Madame C. Audiguier, Fair Maid of Guernsey, M. H. Elliott, Alfred Chantrier, Jeanne Délaux, Elaine, Madame B. Rendatier, Boule d'Or, Mdle. Lacroix, and Val d'Andorre. P. L. Mills, Esq., Ruddington Hall, Notts (gardener, Mr. Hesford), was second with good specimens, from which the premier bloom, a grand example of Belle Paule, was selected, Jeanne Délaux and Mdle. Lacroix also being very fine. Mr. Geo. Taylor, Nottingham, obtained third prize with large blooms, but lacking the freshness seen in the other stands. For six Japanese Mr. Hesford and Mr. Wilson were again successful in the order named. For six Chrysanthemum plants Mr. Wilson was far ahead with well grown plants, and R. E. M. Webb, Esq., Nottingham (gardener, Mr. Collins), second, Mr. Wilson being again first with three plants, and Mr. Collins second. For single specimen plants Messrs. J. R. Pearson & Sons, Chilwell, was first with a grand specimen 6 feet through and by 3 feet high, Mr. Wilson being second.

Fruit was well shown, collections of twelve varieties being keenly competed for. H. R. Clifton, Esq., J.P., Clifton Hall, Notts (gardener, Mr. Anderson), was first, his Gros Colman Grape and Pitmaston Duchess Pears being very good. Mr. C. J. Mee, Wollaton Hall, and C. J. Cox, Esq., Basford (gardener, Mr. Meadows), each showing creditable collections, came next in order. Six dishes dessert and cooking Pears brought out strong competition, as also did a similar number of dishes of dessert and kitchen Apples. Messrs. Attenboro, Meadows, Ince, and Anderson obtained principal honours in these classes. Messrs. Anderson, Booth, and Meadows were the most successful exhibitors of black and white Grapes. Special prizes were offered for collections of vegetables, Messrs. Mee and Dr. Powell being successful. In the classes for Potatoes Mr. Fletcher, Annesley, Notts, obtained the principal prizes, the variety Lord Tennyson being conspicuous in his collection.

The Treasurer, Alfred Page, Esq., the Vice-President, S. Thacker, Esq., and the Chairman of Committee, W. H. Farmer, Esq., each contributed miscellaneous collections of plants not for competition, and the indefatigable Secretary, Mr. E. Steward, assisted by the members of the Committee, superintended the arrangement of the Show.

HULL.—NOVEMBER 22ND AND 23RD.

THE earnest and able officials of the Hull and East Riding Chrysanthemum Society must be congratulated on scoring a distinct success at this their fifth Exhibition. Considering the season the cruel frost in early October that ruined so many plants in the north, and the falling off in the exhibits at some shows, we were agreeably surprised to find the high reputation of Hull as a Chrysanthemum centre so well maintained. Possibly there may not have been quite so many exhibitors as on some previous occasions, and the groups of plants were not so numerous, yet the commodious space was well occupied; and the reduced competition in the plant classes was more than compensated for by the splendid contest in the leading class in the schedule for forty-eight cut blooms, in which the aggregate value of the prizes offered amounted to no less than £47. The challenge vase was, however, generously provided by Lieut.-Col. Gleadow. For these prizes either seven or eight collections were staged, but even taking the lower number it exceeds that of previous shows and represents 336 blooms. Altogether 1851 blooms were exhibited. All

the stands were not heavy, for it was apparent that the earlier and larger blooms of several exhibitors were over, and some that were staged had been reduced by the necessary removal of lower fading florets, yet the leading stands were excellent, and the whole creditable to the exhibitors in making the spirited attempt to share in the honours provided. For obvious reasons particulars of some of the classes of general interest can alone be recorded.

In class 1 of forty-eight blooms, twenty-four incurved and twenty-four Japanese, in not less than eighteen varieties respectively, the prizes were—1, A challenge cup, value 15 guineas, and £15; 2, £10; 3, £5; 4, £2. The awards were adjudged in the following order—First Mr. D. Heany, gardener to H. G. Schintz, Esq., Mossley House, Park Avenue, Liverpool; second Mr. J. P. Leadbetter, gardener to A. Wilson, Esq., D.L., Tranby Croft, Hull; third Mr. J. Stevenson, gardener to Col. Pilkington, The Hazels, Prescott, Lancashire; fourth Mr. W. Mitchell, gardener to W. J. Warrener, Esq., The Moorlands, Bracebridge, Lincoln. The first prize blooms were noteworthy by their good, though not extra large size, evenness, and freshness. They were arranged as follows:—Incurved, back row—Lord Alcester, Queen of England, Golden Empress, Queen of India, Empress of India, Alfred Salter, Lord Alcester, and Golden Empress. Middle row—Princess of Wales, Lord Wolsley, Empress of India, Lord Wolsley, Emily Dale, Mrs. Shipman, Princess of Wales, and John Salter. Front row—Prince Alfred, Mr. Bunn, Lady Hardinge, White Venus, Venus, Refulgens, Cherub, and Jardin des Plantes. Japanese, back row—Boule d'Or, Fair Maid of Guernsey, Magame J. Laing, Meg Merrilies, M. Brunet, Gloriosum, M. Tarin, Boule d'Or. Middle row—Madame C. Audiguier, Jeanne Délaux, Criterion, Belle Paule, Elaine, E. Molyneux, Madame J. Laing, and Duke of Berwick. Front row—Gloriosum, Duke of Berwick, M. Freeman, Mdle. Lacroix, Sarah Owen, Ralph Brocklebank, Elaine, and Criterion. Mr. Leadbetter had some larger blooms in his stands, but some of them were a few days too old, and the "time" did not suit him so well as his successful rival. The other collections followed somewhat closely, the incurved blooms "having it" in one, the Japanese in another stand, but there was no great difficulty in arriving at the average merit of the competing collections.

The next important class was of twenty-four blooms, half incurved, half Japanese, in not less than nine varieties in each section, the Veitch Memorial medal and £5 being offered as the first prize. Very fine stands were placed in competition, the coveted medal being won by Mr. George Lofley, Knighton Church Road, Leicester, with fresh and well finished incurved and very good and bright Japanese, as follows:—Incurved, commencing with the back row and reading from left to right successively—Lord Alcester, Empress of India, Lord Alcester, Queen of England, Lord Alcester, Sir S. Carey, Golden Empress, Lord Wolsley, Mrs. Shipman, Golden Empress, Barbara, and Jardin des Plantes. Japanese—Meg Merrilies, Ralph Brocklebank, Avianche, Ralph Brocklebank, Mdle. C. Audiguier, Avalanche, Gloriosum, Madame C. Audiguier, Madame Lacroix, E. Molyneux, M. Brunet, and Val d'Andorre. Mr. T. Heaney was a good second in this class; Mr. G. Appleton, gardener to C. H. Johnson, Esq., Thorgumbald, following somewhat closely with the third prize.

We now come to another challenge cup class—namely, of twenty-four blooms, twelve incurved and twelve Japanese, in not less than six varieties respectively. The cup, value 10 guineas, is provided by the zealous and popular Chairman of the Society, R. Falconer Jameson, Esq., 3 guineas being added by Mr. E. P. Dixon of the Yorkshire Seed Establishment. Mr. Leadbetter won well (now securing the cup) with remarkably fine blooms of—Incurved—Lord Alcester (2), Golden Emperor (2), John Salter (2), Cherub, Mr. Bunn, Nonpareil, Queen of England, Jeanne d'Arc, Barbara; Japanese—Fair Maid of Guernsey, Marguerite Marrouch, Criterion, Gloriosum, Madame J. Laing, Val d'Andorre, Boule d'Or, Meg Merrilies, Elaine, Comtesse de Beauregard, Golden Dragon, and Mr. H. Cannell. F. W. Jameson, Esq., East Ella, Hull, was second in this class, and Mr. J. Walker, gardener to R. Soames, Esq., Waltham Hall, Grimsby, third with highly creditable stands.

In the class for twelve incurved blooms, distinct, Mr. Heany exhibited a fine stand, the varieties consisting of Empress of India, Lord Alcester, Queen of England, Golden Empress, Lord Wolsley, Jeanne d'Arc, John Salter, Jardin des Plantes, Mr. Bunn, Princess Beatrice, and Lady Hardinge. In the corresponding Japanese class Mr. Leadbetter was the most successful exhibitor, staging, in admirable form, Meg Merrilies, M. Tarin, Elaine, La Triomphante, Jeanne Délaux, Criterion, Madame J. Laing, Ralph Brocklebank, Gloriosum, Val d'Andorre, Elaine, M. J. M. Pigny. Mr. F. W. Jameson was the leading exhibitor in a class of seven competitors, with twelve large Anemone varieties, staging good examples of Marguerite Villageoise (2), Fabian de Mediana (2), Emperor (2), Gluck, Lady Marguerite, La Marguerite, L'Ami Layton, Thorpe Junior, and Grande Alcôve. Also, in the corresponding reflexed class, with good blooms of Dr. Sharpe (3), Mdle. M. Tezier (3), Cullingfordi (2), King of Crimson (2), Chevalier Domage, and Irene. Space forbids the enumeration of other prizewinners; and in reference to the cut bloom classes it can only be said that the exhibits of local amateurs exceeded in quality those of former years; that Mr. Leadbetter staged the two premier blooms in the Show—Lord Alcester and Meg Merrilies; that Mr. Stanley won the first prize for sweet-scented Chrysanthemums with Progne; that three or four varieties in one stand were all "scented" alike; that Mr. G. E. Smith was awarded a first-class certificate for excellent blooms of "Bronze Mr. Bunn," and that Mr. Morton, of Darlington, staged a large representative collection not for competition and very highly commended.

PLANTS.—Hull has become famed for handsome groups of Chrysanthemums with foliage plants arranged for effect. With the exception of Mr. Leadbetter's exhibit, which won with comparative ease the challenge cup and £5, they were, for the reason above stated (October frost) not so good as usual. The second prize was adjudged to Mr. H. Taylor, Newland. Mr. G. Cottam, jun., would have been second if he had not spoiled his group by a profusion of obtrusive white stakes, the remaining prize going to Mr. R. Faleoner Jameson, who did not appear to have the requisite dwarf plants for finishing the arrangement effectively. Mr. G. Lawson was by far the best exhibitor of plants, his standards being admirable examples of good culture and training.

Mr. E. P. Dixon contributed a valuable miscellaneous assortment of plants which were very highly commended, as did Mr. Cottam. Various other exhibitors also aided in imparting variety to the general display.

Nothing could be more satisfactory than the arrangements throughout, and it is only justice to the Chairman, Hon. Secretaries (Messrs. E. Harland and James Dickson), with the Committee generally, to describe the Show amongst the best conducted in the kingdom. It was attended by upwards of 9000 visitors, and it was estimated that 5000 were present at one time during the evening of the second day.

[Just as we are going to press we learn from the Secretary of the Hull Show that the fourth prize in the large class of forty-eight blooms is withheld on the ground that some of the blooms in the stands were exhibited by J. J. Burt, Esq., of Welborn, at the Lincoln Show, this gentleman recognising them at Hull. Mr. Burt and Mr. Mitchell agreed that the whole matter should be referred to Mr. Charles Pennell, sen., of Lincoln, and to abide by his decision. This gentleman, after examining the blooms and hearing evidence on both sides, decided that Mr. Burt has substantiated his claim to the blooms in dispute.]

PONTEFRACHT.—NOVEMBER 23RD AND 24TH.

LAST year a Society was established by a few earnest men to "promote and encourage the cultivation of the Chrysanthemum" in the district surrounding this historic old Yorkshire town. The first Show surpassed the expectations of the Committee, and of the second it may be said that if the exhibits had been more numerous a larger building than the Town Hall would have been requisite for their accommodation, or there would have been little available space for visitors. Not only was the structure quite filled with exhibits, but there was a great advance in the quality of the cut blooms staged, and in some of the classes the competition was very close indeed. Lord and Lady St. Oswald are excellent supporters of the Society, and the Exhibition was opened by his lordship with an appropriate address. The best plants in the Show also came from Nostell, but the able grower of them, Mr. Temple, lost the chief prize through a little defect in the arrangement of his group. The cut blooms, however, demand primary attention.

In the open class of thirty-six blooms, eighteen incurved and the same number of Japanese, in not less than sixteen varieties respectively, Mr. D. Lindsay of Otterspool had no difficulty in winning the first prize of £5, Mr. Morton, Darlington, being a very good second, with Japanese blooms especially, and Mr. W. Pearson, gardener to W. Jackson, Esq., Knottingley, third. The incurved varieties in the winning stands were—Back row—Empress of India (premier), Queen of England, John Salter, Lord Alcester, Queen of England and Empress of India. Middle row—Alfred Salter, Mr. Bunn, Mrs. Heale, Lord Wolseley, Golden Empress, and Prince Alfred. Back row—Princess of Wales, White Venus, Princess Beatrice, White Beverley, Lady Hardinge, and Jardin des Plantes. Japanese—Back row—Madame John Laing (premier), Meg Merrilies, Criterion, Ralph Brocklebank, Fair Maid of Guernsey, and Boule d'Or. Middle row—Boule d'Or, Carew Underwood, M. J. N. Pigny, J. Delaux, Gloriosum, and "Albert de Lion." Front row—Val d'Andorre, M. Astorg, Madame J. Laing, Japonaise, Elaine, and M. John Laing. The stands were very good indeed, and certainly the best that have been seen at Pontefract. In respect to the variety which Mr. Lindsay exhibits under the name of Albert de Lyon, and which has a general resemblance to Elaine, but with longer florets, the lower faintly tinted, is it not the Albert Delcau of the N.C.S. catalogue, and there described as "Silver, rose, and white?" The difficulty in deciphering the names on French and sometimes English labels is well known, and the popular rendering "De Lion" might easily have been deduced from Delcau. It requires a critical eye to distinguish this variety in some of its stages from Elaine, as the "silver rose" is not apparent on the surface; a difference, however, is discernible in the character of the florets. Both at Birmingham and Pontefract some growers did not regard the two varieties named as distinct, but they were allowed by the Judges. This small digression may perhaps be permitted. To resume. Mr. Morton staged in his good stand of Japanese a white variety named Condor, effective by its broad and long strap-shaped florets. Mrs. Beale and Mrs. Langtry, fine blooms of Meg Merrilies and Ralph Brocklebank were also noticeable in collection. Mr. Morton secured the chief prizes with twelve incurved varieties, also with twelve Japanese, the former comprising John Salter, Lord Alcester, Empress of India, Queen of England, Princess of Wales, Baron Beust, Prince Alfred, Golden Empress, Golden Beverley, Barbara, Mr. Bunn, and Lady Hardinge; the latter, Ralph Brocklebank, Belle Paule, E. Molyneux, Meg Merrilies, M. H. Wellem, Boule d'Or, Madame Lacroix, Duchess of Albany, Gloriosum, Florence Percy, Mr. Garnar, and Stanstead White.

A silver cup was offered for twenty-four blooms, half incurved and half Japanese, in not less than six varieties, and not more than two of one variety in each section. The prize was won in a close contest by Mr. Dunn, gardener to Mrs. Jones, Elmsall Lodge, Pontefract, with (incurved) Empress of India (2), Alfred Salter, Queen of England, Lord Alcester (2), Mr. Bunn (2), White Venus (2), Lord Wolseley, and Beauty; (Japanese) Boule d'Or (2), Belle Paule (2), Val d'Andorre (2), Madame C. Audiguier, M. Tarin, Gloriosum, Elaine, Mrs. H. Elliott, and Madame Lacroix. The second prize blooms of Mr. McCleave, gardener to R. H. Jones, Esq., Badsworth Hall, were generally larger, but some of them a week too old, John Salter and M. John Laing being within a shade of winning "premier" positions. Mr. Pearson had the third prize, his stand containing neat and good blooms. There was excellent competition in the other local classes. Mr. C. Ketchell, gardener to C. H. Simpson, Esq., Ackworth, winning many first prizes, while Mr. John Sunley and Messrs. J. & R. Calam were successful with bouquets.

Mr. W. Pearson secured the chief prize for a group of Chrysanthemums, a free and informal arrangement, Mr. Temple having better plants and blooms but staked up too formally for producing a pleasing effect, hence he was placed second, and Mr. Bull, gardener to John Rhodes, Esq., Snydall, third with a free arrangement but blooms too light. Miscellaneous groups of plants were effective, Mr. Ketchell securing the first position, but his plants though good and bright were too formally packed. Mr. Pearson was a dangerously close second, a few weedy-looking Marguerites perhaps losing him the higher position, and Mr. B. Hartley a good third. Excellent Roman Hyacinths were exhibited by Messrs. Ketchell and Moxon, the first-named exhibitor being first with black Grapes, capital examples of Gros Guillaume, Mr. Pearson closely following with Alicante. Mr. D. A. Neilson had the best white Grapes, and Rev. G. Haslam, Brotherton, the best Tomatoes, very fine. Well finished bunches of Golden Queen Grapes exhibited, not for competition, by Mr. Lindsay, were highly commended. A number of good exhibits must be passed, and after indicating the main features of the Show it only remains to say that in Mr. Thomas Glover the Society has a most courteous and industrious Hon. Secretary, and the Committee have given proof by their work that they merit the support of the affluent in developing high culture and producing a floral treat for the inhabitants of the district.

RYDE, ISLE OF WIGHT.

THE cultivation of the Chrysanthemum is making headway in the Isle of Wight, the above Exhibition being pronounced far ahead of the previous ones. With such an enthusiast as Mr. James O. Brook at the head of the Committee, and Mr. James Eley as Secretary, much interest is thrown into the work of the Society. Apart from the ordinary classes for cut blooms special prizes were offered for vases, epergnes, bouquets, and baskets of cut Chrysanthemums and foliage, which added to the interest and attractions of the Show. There is also a special prize of a piece of plate, valued 2 guineas, for a stand of triplets with Ferns or foliage in what is known as Cannell's style, which has a very pretty decorative effect. The special prize offered by Mrs. J. O. Brook for a basket of cut berries, autumn foliage, and Ferns brought a competition far ahead of anything seen near the metropolis, the combination of colours being exceedingly attractive and the arrangements elegant and tasteful. Groups of Chrysanthemums did not display much quality, the first prize going to Mr. Taplin, Mr. James second, with Mr. Barnes third.

The style of plants adopted with one exception is the upright half-bush style, fit for conservatory work, the majority measuring from 3 to 5 feet over, and bearing fine heads of bloom of fair average quality. Mr. Wilkins, gardener to W. S. Ridley, Esq., The Castle, St. Helen's, was the chief exhibitor in the plant classes, and the Wood Memorial medal, offered for the best exhibit of Chrysanthemums in the Show, was awarded the six plants of Japanese exhibited by him, amongst which was a fine plant of Madame J. Laing. Mr. A. Tolley, St. Helen's, and Mr. J. Woods of Ryde also exhibited well in the plant classes.

CUT BLOOMS.—In the open classes for thirty-six cut blooms, eighteen incurved and eighteen Japanese, Messrs. W. & G. Drover was first with a grand lot, showing in their well-known style. The same exhibitor was also first in the class for Anemones, and first for six of any one variety. The chief interest was centred in the contest for the silver challenge cup, offered for twenty-four distinct, Isle of Wight only, to be won twice before being claimed. Last year it was won by Mr. G. Wilkins, but this time it was wrested from him by a stand of good blooms exhibited by Mr. Earle, gardener to Henley Grosse Smith, Esq., The Priory, St. Helen's, of Orchid renown; Mr. Wilkins was second, and Mr. H. Drover, florist, Ventnor, a good third. In the classes for incurved blooms Mr. Earle carried off the honours, and Mr. Wilkins was first with good stands in the Japanese classes, Messrs. J. O. Brooks and J. Woods showing well in the Anemone and reflexed classes. For eighteen triplets shown in Cannell's style Mr. Attrill was first with a stand of excellent quality, effectively arranged, Mr. A. Tolley second, and Mr. J. O. Brook third. For an epergne or vase Miss Shaw was first, Miss Brook a good second, with Mrs. E. Brook third; and for a bouquet Mr. Taplin was first, Mr. W. Jeffery second. For a basket of ornamental foliage and berries previously mentioned Miss L. Belcher secured the first prize, Miss E. Nutt second, and Mrs. C. Prince third, other ladies showing well in a close competition. In the fruit classes Messrs. F. N. Broderick, Taplin, Richards, Martin, and Mr. Alderman Colenutt, the Mayor of Ryde, were the chief prizetakers.

FRUIT FORCING.

PINES.—During the next two months it is likely the weather will be sunless with cold nights, which is not at all favourable to vegetation, yet in the cultivation of Pine plants rapid progress at this time of year is not advisable. It is better to rest content with a slow advance being made in a steady uninterrupted manner; hence the temperature should be lowered to its minimum in each department, which for the fruiting house should range from 65° to 70°, successional houses 60° to 65°, and for suckers 55° to 60°, allowing a rise of 5° to 10° from sun heat. The house containing the fruiting plants will need constant attention in sprinkling the pathways and moistening other surfaces in the house as they become dry. In airy houses the plants will need to be lightly syringed at least once if not twice a day. Examine the plants at intervals of not less than a week, and give tepid liquid manure abundantly to those which require it. Plants in fermenting beds do not, as a rule, require nearly so much water as those subjected to the heat arising from hot-water pipes; but, notwithstanding, the plants must be looked over at least once a week. In succession houses and pits, where less heat is applied, a moderate and equable state of moisture should abound, and no more fire heat be employed than is absolutely indispensable, which, with covering over the lights at night, will in a great measure dispense with fire heat, and therefore should be employed whenever practicable. Take care that the plants have the full benefit of light in every division by keeping the glass clean.

VINES.—*Early Vines in Pots.*—Pay attention to fermenting material in pits, which, as every pot is placed on a solid pedestal built from the bottom of the pit, will admit of frequent additions being made as the heat declines, the whole mass being turned without displacing the Vines, and root action will be all the steadier and less liable to be checked when the pots are only partially surrounded by the plunging material. Afford liquid manure whenever moisture is needed in a tepid state, and cease syringing the Vines after the bunches show, when the final disbudding should be made, leaving the most promising with a surplus for contingencies. Stop the growths a couple of joints beyond the show of fruit, laterals below the bunch at the first leaf, and those beyond may be allowed to extend as far as it can be done without crowding the principal foliage. Keep the temperature at 65° to 70° by day, 5° to 10° more from sun heat, and 60° to 65° at night, damping available surfaces two or three times a day.

Early Forced Planted-out Vines.—When the buds in the house that was closed about the middle of November show signs of swelling, give the inside border another supply of water in the case of vigorous young Vines, and liquid manure when they are old and require stimulating. This should be applied at a temperature of 80° or 90°, and if not already done some good fermenting leaves and stable litter laid in heaps or ridges on the borders will help the surface roots and give off a genial moisture to the atmosphere, reducing the necessity for hard firing and incessant syringing. Young Vines that have not been forced early will require bending down to a horizontal position to insure an even break down to the base, but old Vines may be tied to the trellis immediately they are pruned, and will usually break freely.

Succession Houses.—Take advantage of unfavourable weather outdoors to get Vines pruned, always bearing in mind that early pruning conduces to a strong and even break when the time arrives for forcing. In dressing the Vines do not remove more than the loose bark, and wash with soap and water in preference to a composition which leaves a thick deposit. Thoroughly cleanse the glass with water, the woodwork with soap and water, and the walls with limewash. Remove the loose surface soil, and give fresh material; lumpy loam with a little charred refuse and steamed bonemeal, or some approved fertiliser, may be similarly employed.

Late Houses.—The attention of growers has frequently been directed to the importance of starting the Vines and helping them forward with fire heat in the spring, as being safer and more economical than trusting to sun heat during the early part of the season and having to employ fire through the autumn to have the wood and fruit ripe, or apparently so, by November. In fine hot seasons it may answer well enough, but in a cold wet season the Vines hold the foliage until it is displaced or liberated by a rapid depression of temperature. This sudden check is not ripening, and the chances are that the Grapes, particularly such varieties as Mrs. Pince and even Lady Downe's, do not retain their colour and freshness until the time arrives for cutting in January; and when Grapes begin to shrivel on the Vines it is useless trying to keep them in the Grape room until May. This is given for the benefit of those who have not hitherto made a start sufficiently early to insure a satisfactory result in autumn. All Grapes intended for keeping fresh and plump for some months after they are cut should now be hanging on leafless Vines that had completed their season's growth and ripening by the end of October. Where Vines are in this condition the Grapes will keep satisfactorily with the temperature falling as low as 40°, with just sufficient fire heat to dispel damp and protect them from frost; but fire heat after the leaves fall must be sparingly applied, particularly to

Muscats and thin-skinned varieties that soon begin shrivelling in a warm, dry atmosphere; whilst in a stagnant moist one they are very liable to spot, and when that sets in all further chance of keeping the Grapes is gone. In damp weather, when the external air is charged with moisture, the house should be kept dry, cool, and close, and when the nights are clear and frosty light non-conducting material such as scrim canvas, or even fishing nets drawn over the roof, will prevent the radiation and economise the fire heat, whilst the subdued light is rather beneficial than otherwise to the Grapes, and certainly does no harm to the Vines.

PLANT HOUSES.

Chrysanthemums.—As the flowers fade cut down the plants within a foot or a few inches of the base, and stand them in a light airy structure to induce them to produce strong cuttings. Any plants that have pushed up weak growths from the base should have them removed, so that good cuttings will be produced by the time they are wanted. The plants will need considerably less water, in fact only sufficient to keep the soil in a moderately moist condition. Plants for late flowering that are only just swelling their flower buds will be benefited by weak stimulants or artificial manure applied to the surface of the soil. Keep these as cool as possible by admitting air freely by day as well as at night on all favourable occasions. If aphides attack any of the plants fumigate lightly with tobacco.

Roses.—Tea Roses that are outside with their pots unplunged should have the protection of a cool house or cold frames. All plants required for very early forcing, whether Tea varieties or Hybrid Perpetuals, should be pruned without delay. The unripe ends of such varieties as Gloire de Dijon may now with safety be removed, and the houses they occupy thoroughly cleaned. Keep all as cool as possible that are not required for forcing before the beginning of the year. If red spider or mildew exists upon the old foliage of the plants at pruning time remove the foliage—that is, from those with well-ripened wood that will be forced into bloom. If insect-infested foliage is left upon the plants until they have produced young growth it will soon be attacked, and red spider and mildew may prove a source of annoyance the whole season. From plants that will come naturally into flower the old foliage, if not infested, should not be removed for some weeks.

The Forcing House.—It is a good plan where practicable to set a house apart for the purpose of forcing such plants as the varieties of Azalea indica, with the Ghent and Mollis type, Guelder Roses, Laurustinus, Rhododendrons, Lilacs, and similar plants. The plants start freely, almost naturally, if stood upon a bed of fermenting material. This should be principally composed of leaves that have been stored in a dry state. A little litter may with advantage be added, but this should not be too near the surface so as to interfere with plunging the pots. Be careful not to use too much litter, or a violent heat will be created which will do more harm than good by unduly exciting the plants. All that is needed is a gentle moist heat such as a bed of leaves is capable of yielding. The varieties of Azalea indica should not be plunged, but merely stood on the surface. The other plants will bear plunging without injury. Pot hardy shrubs for forcing, and arrange them with Deutzias, &c., in Peach houses and vineries as they are prepared for starting. The forcing house can then be supplied from these structures. The greatest success attends the forcing of these plants by starting them gently at first.

Bulbs.—Hyacinths, Tulips, and Narcissus, as soon as they are green after removal from the plunging material and display signs of growth, may with advantage be stood amongst hardy shrubs in the forcing house until they display signs of vigorous growth. They must then occupy a position close to the glass to prevent their foliage and flower spikes becoming drawn. Tulips will require brisk heat to bring them forward, and the pans or boxes in which they are grown may be plunged amongst the leaves. Our earliest Tulips are produced by plunging the pans containing them in close propagating frames. A few Amaryllises may be introduced to the forcing house, these may be plunged as soon as the bed is ready for them.

Lily of the Valley.—Early frosts sent these to rest sooner than usual, and imported crowns are coming forward this year very freely. The best way of forcing these early is to lay the crowns closely together in cocoa-nut fibre refuse, covering the crowns an inch or more below the surface. They should be in close frames, where they can enjoy brisk bottom heat. This course is necessary for all that are needed up to the end of the year. After that time they will come forward freely enough in any warm moist structure. Spireas should be plunged in brisk bottom heat, if the flowers are required as early as possible.

SIGNS OF THE TIMES.

As we are approaching the close of another year we may take a glance backwards in the annals of bee-keeping—say for thirty years or more—and compare it with the present and last dozen years. In the first named epoch the same principles in the art of bee-husbandry as now practised were then advocated in these pages,

and then (as now) they were carried out to a successful issue. After a while new teachers appeared, who either knew not or entirely ignored the then existing satisfactory state of good bee management. One "idea" after another rose in rapid succession, but to fall as suddenly as they rose. Rational bee management in all its forms was denounced, and interested persons for a time held the sway. This continued for about a dozen years or more, with perhaps more than that number of different kinds of hives, every one of which was an improvement on the one previously launched as the best and eclipsing all others.

The British Bee-keepers' Association's ten-framed standard, with which no other kind of hive was allowed to compete at shows under their auspices, has had its rise and fall. The old Stewarton system of placing an empty raise beneath stocks during winter, as well as that of giving wide entrances, is but being introduced in some quarters, and one writer recently seemed to regard it as new and his own idea. In America many other things we have long taught and practised are just being tried, such as our living apparatus, clearing supers of bees (the latter perfected by me with the carbolicised paper years since), then the possibility of transmitting honey in paper packages, is receiving their attention. Several years ago I put this to test, and lately I had samples of honey sent me successfully by post in paper. The above are but a few matters that are being discussed which we have practised for a long time.

It is a trying season such as the past one that tests the bee-keeper and his system of management, and when we find a number of bee-keepers located near each other managing their bees on different principles, one being successful and the other not, it is safe to assume that success was due to hives and management. Within the last month I have received upwards of a score of letters from different localities, all the writers having had a fair average honey harvest of from 40 to 50 lbs. from each hive. Nearly every one of these ascribe their success to information in this Journal.

In future articles I will be guided, as previously, by the state of my own bees, always keeping in mind the difference that exists between the seasons in different parts of the kingdom. Meanwhile, I advise all who contemplate making any change in hives and system of management; to embrace the opportunities that often arise during the winter months, and get all in readiness for the summer of 1889, which, it is to be hoped, will be more lavish in her gifts in the way of sunshine and nectar than 1888 has been.

SUPERS.

As small supers are in greater repute with many bee-keepers than sections, it will please some to learn that these can be had at an outlay of about 7d. per dozen for material. The wood is of two thicknesses. The sides and top bars are one-eighth of an inch, and front and back five-sixteenths of an inch. All should have a slight planing, and the upper edge forming backs and fronts should be rebated. A common three-eighth match plane does this. After a number of lengths are cleaned, rebated, and clamped together, set a compass to the lengths required, mark and square over them, cut to the line, and the pieces are ready for nailing. The bars averaging $1\frac{1}{4}$ inch broad ought to have a groove in the centre for the foundation. It can be made with a circular saw or a drawer bottom plane. The sides of the supers should be from 4 inches to $4\frac{1}{2}$ inches broad.

There are no better receptacles for honeycomb than these small supers holding about 5 lbs. each, and they are the cheapest and handiest in every respect, while they are unsurpassed for marketing purposes, and command a ready sale, often too, when sections are a drug on the market.

HOW LONG DO QUEENS CONTINUE LAYING?

"J. B. J." asks, "How long do queens continue to lay?" When a hive is fairly populous, and in a normal condition as to health, &c., the queen of such a hive begins to lay shortly after the shortest day, and continues to do so until the month of September,

when, as a rule, queens of a year or more old discontinue to deposit eggs, and the bees naturally cluster up. But if feeding be resorted to, or a change of situation take place, and the hive well filled with honey, breeding will be resumed, and continued until stress of weather puts an end to the flight of the bees. Young queens especially Syrians, will sometimes breed the whole winter. But all varieties seek a time for repose.—A LANARKSHIRE BEE-KEEPER.

ERRATUM.—In the third paragraph, page 479, third line from bottom, "the bottom box first and work upwards," should read, "upper box first and work downwards."

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Book (W. C.).—The work you mention has been long out of print.

Address (C. O. S.).—The address you require is Mr. W. Collins, 9, Martinhoe Terrace, Martindale Road, Balham.

Bouvardias Sporting (J. J. S.).—These plants are much given to "sporting," and the double varieties possess a similar character. Cuttings of the shoots bearing the flowers differing from the parent may, if rooted, retain their character.

Chrysanthemum Sport (E. M.).—The sport seems to be a promising one, but you would do well to place it in the hands of an expert grower for exhibition, who another season would prove whether it is really distinct and valuable.

Buttonhole Holder (J. R. B.).—The holder you send is a simple and efficient one, the indiarubber cap preventing the water escaping, and also serving to retain the buttonhole in its place. No doubt, if well advertised as you suggest, it would obtain a ready sale, especially as the price you mention would be a moderate one. Ordinary holders are much used, and it is probable when the improvement was made known the demand would be increased.

Camellia Buds Falling (O. T. R.).—Assuming the buds were well set on ripe wood their falling is either the result of defective root action, the consequence of the soil getting too dry occasionally—it may be some weeks ago—or of a sudden change of conditions, such as removing them from a damp house, or from the open air, into a dry structure. You should have stated the conditions under which they have been grown and the treatment to which they have been subjected.

Cinerarias Flowering Prematurely (Idem).—When Cinerarias "show flower buds instead of growing" it is certain there has been some mismanagement. The plants may have been crowded too long in the seed pans or pots, have been too dry, placed in a compost not favourable for free root action, been too root-bound before repotting, or in some other way received a check. The mixture you name would have been more than rich enough without the soot, and an excess of this arrests instead of promotes the growth of these and other plants.

Misnamed Vines (Kiltennan).—No one can tell you "with certainty" the name of the Grape from one shrivelled berry. You ought to have sent sooner, also have sent samples to the nurseryman who supplied the Vines, and he, being a man of high character, would regret any mistake on the part of his assistants, and doubtless supply other Vines gratuitously if convinced of the mistake. The berry resembles Foster's Seedling, and the leaf also, but the examples are insufficient for positive identification.

Preparing Manure (Sewage).—There is nothing so good as dry soil, and the drier and finer it is the better for mixing with the contents of the closet, sufficient soil being used for clean and free incorporation. If you have plenty of powdered charcoal or dry wood ashes, a quantity of either could be used also with great advantage. The mixture would be of great value for top-dressing plants that need assistance, and Vines. It must be used cautiously, however, as it will probably be much stronger

than the native guano of which you speak, but that of course depends on the quantity of soil used in the mixing.

Exhibiting Pompon Chrysanthemums (*J. S.*).—If spikes or bunches are stipulated for in a schedule with no reference to the number of blooms, it is understood that no limitation to three blooms is desired by the authorities of the Shows, and Judges make the awards on the merits of the spikes or bunches, whether each contains three blooms or thrice that number. The most satisfactory way of exhibiting Pompons is in bunches of three flowers, one on each stem, with foliage, the flowers to be not less than 3 inches above the board. If this were clearly stated in schedules all exhibitors would know what to do, and examples of culture would be best represented.

Gardening in America (*H. G.*).—We cannot tell you "to what extent gardening is carried out in the neighbourhood of New York," but an American horticulturist recently told us that well-educated, competent, and industrious British gardeners, industrious and, to cite his own description, "gentlemen in conduct and address," had a very good chance of prospering in the United States. We do not, however, advise you to go there without first writing for information and advice from such a representative horticulturist as Mr. Peter Henderson, 35 and 36, Cortlandt Street, New York, enclosing a directed envelope and the requisite amount in stamps for covering postage for the reply.

Premature Defoliation of Plum trees (*H. B.*).—We think we understood the case as far as you explained it, and do not see any reason for modifying our reply, which, however, you do not question. Nor can we add much to it. We know of no particular fungus that attacks the Plum, but the leaves are apt to assume a silvery hue and then fall. This silvery appearance, not being mentioned by you, yet is so conspicuous, we assume your trees were not thus infected. The transparent appearance is caused by the separation of the laminae or skins of the leaves, leaving a cavity between them, but the origin of the evil, for evil it is, is not known. "As some red spider could be seen" on the leaves, far more were no doubt there, but not seen, and we still suspect insects were active agents in the defoliation, assuming the absence of the silvery hue on the leaves to which you do not allude.

Dividing Agapanthus umbellatus (*R. O.*).—The plants may be divided as soon as they have flowered, which under glass is during the early summer months. Cocoa refuse for potting should be thoroughly decayed, and may then take the place of leaf soil, or about one-third of the compost. It is no detriment to Begonias kept through the winter in boxes or otherwise after being shaken out after the foliage dies down, only they should be potted before or immediately they begin to grow. We should not like to say how long the tubers are before they begin to deteriorate, but we should think it must be a lengthened period, as we have had them for many years without noticing any failure; but, on the contrary, they have increased in size and vigour of plant under good treatment, and when they have gone off it has usually been from decay consequent on injury.

Culture of Anemones in Pots (*M. N.*).—The roots should be potted without delay, placing them about 1 inch deep in good loamy soil, with a fifth of well-decayed manure intermixed with a sixth of sand. They may be placed about 1 inch from the sides of the pot, and 2 inches apart around and inwards. The soil should be moist, and a good watering given after potting, standing the pots on and plunging in ashes in a cold frame. There they may remain with air on all favourable occasions, and protection from frost and during severe weather until they are well rooted and have made a little top growth, when they may be placed on shelves close to the light so as to prevent their drawing, and where they will have a free circulation of air, keeping the plants duly supplied with water, and affording weak liquid manure occasionally. Anemones do not stand much forcing, but the flowering may be accelerated by placing, after they are somewhat advanced in growth, in a house in a light airy position with a temperature of 45° to 50°.

Vine Outside Greenhouse (*W.*).—We are still quite at a loss to understand how three-fourths of the length of rods could be taken out of the "top window" of a greenhouse of a Vine planted in the front and trained up the roof. The point, however, is not of importance, and we accept the fact that a large portion of the Vine, and probably the best portion, was taken out of the house in September and trained up the wall for ripening the wood. We do not approve of the plan, heat, not cold, being the chief agent in wood ripening. Assuming the wood of the Vine is hard and matured, as it may be, it will not be injured by exposure to frost, as we presume the wall to which it is trained faces the south. We have known Vine rods systematically taken outside houses, after the wood has ripened in them, for the winter, and the pruning completed. You must not defer pruning your Vine till the spring, and the sooner the work is done the better; and as you wish to keep a higher temperature in the house than the Vine would rest in, the rods can be left outside during the winter and introduced in the spring. This advice is given on the assumption that the wood is matured, as if not it might be injured by severe frost. Cut back to where the wood is hard—you will not be likely to err in pruning too closely. We give you the best advice we can under the circumstances, but must decline all responsibility for a possible inferior crop of Grapes next year, at the same time hoping you will have a good one, though you have not, in our opinion, adopted the best method for producing the desired result. We suspect the leaves would be injured by dragging the rods outside and sudden exposure. If you had submitted the proposition of the "local gardener" to us we should have advised a different method of procedure, though there is

the possibility of no great injury resulting from the rough treatment to which the Vine was subjected.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*James Hartland*).—The Pear is Urbaniste. (*J. Mooreby*).—1, Rhode Island Greening; 2, Golden Reinette, a very fine specimen; 3, Lord Suffield. Australian plants require greenhouse treatment as a rule, but we do not know one of the name you mention.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Lady King*).—*Pernettya mucronata*. (*Reader*).—1, A very imperfect specimen, but it resembles *Rhaphis flabelliformis*; 2, *Agapanthus umbellatus variegatus*; 3, *Lomatia propinqua*. (*Scott*).—A small flowered variety of *Odontoglossum odoratum*. (*N. C.*).—*Dendrobium cburneum*. (*P. A.*).—The plant is apparently an *Oxalis*, but it is impossible to determine the species from two or three crushed leaves. It is doubtful if it would prove hardy in this country, but it would be safe in a greenhouse. We are glad to learn that you find the Journal useful. (*E. Keeth*).—The tree is *Pyrus torminalis*. (*W. J.*).—The plant is *Melilotus officinalis*, and is, in a fresh state, greedily eaten by cattle, also when dried, if the stems are not too hard, which seems to be the fault in the specimen sent. (*J. B.*).—The variety is White Christine, also known as Mrs. Forsythe.

SHEEP MANAGEMENT.

At the end of the lambing season folding upon late-sown Swedes and white Turnips begins, delicate ewes and ewes with weak lambs being kept back from the folds as long as they require extra care and shelter. Lamb cloths are generally fastened to the hurdles along the windward sides of such folds for shelter, but we use in preference straw-thatched hurdles, as not only affording more shelter, but as a test of the feeding of the ewes, for if they are kept short of food they invariably consume the straw upon the hurdles. The food question must now, indeed, have careful attention. The ewes should have a pound of crushed oats per head daily, with plenty of fresh sweet Bailey, Oat, or Pea straw chaff. We like also to have a rack or two of whole Pea straw out in the middle of the fold. Such straw racks afford some shelter, and attract enough sheep from the thatched hurdles to cause a more equal distribution of manure than could otherwise be managed. If the flock crowds together overmuch for shelter an excess of manure at such spots often causes rank growth subsequently in the Barley crop. Such overgrown patches of Barley go down before rain or wind, the crop ripens unevenly, and the sample suffers accordingly.

If the lambs are simply required for stores, a little bran, followed later on by a few crushed Oats, is sufficient with the roots to keep them in good health. But if we would push them on as fast as possible, the bran soon gives place to "Lamb Food," consisting of a well balanced mixture of crushed linseed and compound cakes, with peas, Malt culms, Oats, bran, and other farinaceous food, all carefully crushed and mixed. Care is taken not to overfeed, and to clean out the trough thoroughly every day. The lambs are kept with the ewes till the first or second week in June. We have known them to be kept with them fully a month later, but this is unwise, the strain upon the ewes from such protracted suckling being so severe that they are sadly reduced in condition, and if used for breeding next season many die outright, and most of the lambs are weak and delicate.

Rye follows the Turnips, folding still being continued, and Mangolds are given with the Rye and dry food. After the Rye comes Rye Grass, Sainfoin, Tares, or Lucerne. A few of the most forward lambs may be sold to advantage as fat lambs. We have realised as much as 50s. apiece for exceptionally fine ones by the first week in April, but as a rule 35s. may be given as the full value of fat lambs in April and May. A lot of money will be made upon lambs this year by those who could afford to keep them on to the hogget stage, or purchased early for that purpose when they were cheap. On November 14th in the sheep market at Bury St. Edmunds, half-bred Cotswold and Suffolk hoggets eight months old realised 58s. per head, and pure black-faced Suffolk hoggets of the same age 63s. 6d. per head. Such early maturity indicates profitable farming, the profit arising from it being found in the fertility of the land upon which they were folded as well as in the high price of the sheep.

Ewe lambs answer as well as wethers for high feeding, for they are available for breeding in the first season, and are subsequently all the better for it. We are aware of the general preference—may we term it prejudice?—for not breeding till the second year, but from experience we are bound to say it answers best to push on the ewe lambs and put them to the tup at the age of eight or nine months. Our best flock of ewes was home-bred, and although the fall of lambs from them the first year was not a full one, yet subsequently their lambs have been decidedly superior to those of another flock of ewes of different ages got together by purchase.

We know it is considered that age alone imparts flavour to mutton, but farmers cannot afford to retain sheep upon their hands for a mere fancy. They have to provide food for the masses, and every week gained in the completion of the process should add to the profits. Early maturity is possible in all animals of the farm that are kept for the butcher, and early maturity therefore we must have. In feeding sheep for such a purpose the high dietary is liable to induce a feverish condition, which is connected by change of diet and plenty of green food or roots. A change from arable to pasture land for a few hours is also good, but animals while being fattened only require a moderate amount of exercise—enough for health, but not enough to cause fatigue. They also require protection from undue exposure to cold and wet. Some of the most profitable sheep we have had were finished for the butcher during the last month or two in yards.

(To be continued.)

WORK ON THE HOME FARM.

Wet weather has proved a serious hindrance to late Wheat sowing, but the rain has done much good to all winter corn already in the land. Rye, Beans, Winter Oats, and Wheat are all a good strong full plant, and though late another year's work has been fairly well begun. Long will 1888 be remembered for its remarkable changes of weather. A series of extremes has continued from the beginning of the year up to the present time, and there is nothing else possible only to keep plodding on and be always on the alert to turn every change to fair weather to account. We have still heavy arrears of ploughing to get through with, and every effort will be made to push on this important work now. Land intended for Mangolds next season should first of all be ploughed in the ordinary way, and then if the weather prove favourable it should be ridged high with the double breasted plough, and so left till spring. When this ridging is done before Christmas there is always a temptation to cart much into the furrows when the land is frozen hard, but unless there is a fair prospect of splitting the ridges so as to cover the muck with soil immediately afterwards the exposure of much in small quantities in this way for an indefinite period of time is most objectionable, for very much of its goodness is lost, and we have just so many heaps of humus void of the fertilising gases which ought to have been absorbed in the soil, but which have been lost in the air. We use some muck for Mangolds, but we never cart into the furrows till the plough can be used to cover it.

With our magnificent store of Mangolds this winter we can afford to use them freely for horses, cows, pigs, and in fact all the live stock of the farm. Even the poultry are fond of them, and it is really curious how soon a few hens will consume a huge root. We do not use them for sheep till the lambing; a few may be used previously if hard weather sets in, but roots of any sort should always be used in moderation among pregnant ewes. Cattle Cabbage are held in reserve for them at present till green food on the pastures becomes scarce, the Cabbage are then followed by Mangolds, and Thousand-headed Kale comes in still later on.

OUR LETTER BOX.

Green Fodder (J. J. S.).—Sow Rye and Tares at the first opportunity the soil is in suitable condition, mixed or separately as you prefer. Many persons sow in mixture on the ground that the Rye holds the Tares up to some extent. Make another sowing during the first fine weather in spring, and when the plants appear sow again. If you sow the whole plot at once, you may have more than sufficient produce at one time and not half enough at another. This appears to have been so in the case of the Trifolium.

REMARKS.

18th.—Slight showers in the morning, cloudy day.

19th.—Cloudy throughout.

20th.—Heavy rain in small hours, bright fresh day, with strong wind.

21st.—Fine and bright throughout, except for a sprinkle of rain about 3 P.M.

22nd.—Cloudy and mild day.

23d.—Overcast and windy.

24th.—Cloudy throughout.

A fine pleasant week, with a fair amount of sunshine. Temperature equal to the mean being about 1° above the average.—G. J. SYMONS.

THE VINERY IN WINTER.

CONTINUING this subject from page 484, it is necessary to emphasise the remarks on the thorough cleansing of not Vines only in insect-infested houses, but every inch of the structures, and especially those parts out of sight. During the present week a vinery, put in order for the winter, has been visited. The Vines had been pruned and dressed with tar and clay, as "mealy bug had been so bad;" but under a stage formed along the front of the house Gloxinias were stored away, and at the base of the withering stems masses of fluff were visible, and a removal of some of the soil revealed nests of the dreaded Vine pest. Its presence was also too apparent on the under surface of the stage, and especially at the foot of the front wall in the dry soil behind the hot-water pipes. There were thousands of insects. The man in charge appeared to think he had done all that was needed in tarring the Vines, as he had been told that was a "certain cure for the mealy bug." There is no certain cure short of absolute eradication from the house of which the pest has taken possession, and applying matter to the rods of Vines alone is utterly delusive. Such dressings may have done good in conjunction with other efforts to subdue the enemy, but not without them, and experience has proved, not in one case, but many instances, that it can be banished without the tar, and has been completely eradicated before that "remedy" was heard of; still, those who like tar can use it, as tastes differ, and every man to his taste.

Some persons have been seen to go the wrong way to work in pruning and cleansing Vines and vineries. They first prune, peel, and dress the Vines, then wash the rafters, sashbars, and wires. The pruning should be done first, but the cleansing of the Vines last. If the roof is done last some insects may fall from there on the rods, but they cannot do so if the roof-cleansing has been complete. The glass and woodwork should be washed with clean hot water, the hotter the better, both for effective cleansing and quick drying. Soapy water clouds the glass, and that is not good for plants in winter. When the woodwork is dry it will be ready for painting, if that is needed or is to be done, for everything that is needed in gardens is not done nowadays; but what can be done at trifling cost, and what should be done in vineries where insects abound or have been prevalent during the summer, is to dress the woodwork with petroleum, forcing it well into every fissure with a brush. The wires must be similarly dressed after every bit of matting and dry tendril is removed. Leaving these almost certainly means leaving insects in the coils. This may appear a small matter to dwell on, but many an example of its non-observance has proved the necessity; and probably no man who has habitually overlooked small items and apparent trivialities has won distinction above his fellows in any vocation, and certainly not in gardening. Let young men particularly bear that in mind, for it is true. In small things as in more advanced duties, in work hidden as well as that in view, be thorough, slurring over nothing. As much pains should be taken in crocking a pot as in making a bouquet, and it is impossible to bestow too much care in cleansing insect-stricken vineries. Walls must be as well washed as woodwork. Hot lime is an excellent insecticide and purifier, and it is cheap. When all this is done we come to the Vines.

Peeling and scraping all the bark off Vines, and polishing the rods as if they were to be made into walking sticks for dandies, is

one of the most stupid practices that ever grew into a system. When infested with insects it is no doubt advantageous to remove the loose bark, including the scaly parts round the spurs. There is a good and distinct reason for that—namely, the exposure of insects to the applications for their eradication. If an enemy lurks behind ambuscades the sheltering agency must be removed, even if a little mischief is done in the process; but to do injury without a justifiable object is wanton, and no justification has yet been established for forcibly, and at no small trouble, stripping clean Vine rods of their natural covering. As a non-conducting medium the bark of Vines prevents those sudden chills to the sap, affecting its fluidity, during sudden falls of temperature in spring, while its absorbent nature is conducive to healthy growth by insuring much more uniform humidity than can be possible when every particle of the moisture-retaining substance is removed. In this event, the skinning, perhaps, then "painting" with clay as the medium for holding something else, may be of a little use, though applied for another purpose. But Vine rods can be cleansed without such violent skinning as they are often subjected to, even if there are insects lurking in the fissures; while if there is none the operation is inexcusable, and the dirty daubings superfluous.

It is prudent to wash Vine rods that are supposed to be free from insects, because supposition is not certainty, and the operation costs next to nothing, and cannot possibly do harm; but when insects have been troublesome on Vines in summer, rod-washing in winter is imperative, and must be done in a very thorough manner, with a solution that cannot do the Vines any harm, but which will rid them of their enemies. Gishurst compound will answer, or softsoap; a quarter of a pound of either, dissolved in a gallon of soft boiling water, violently stirring in a 2½-inch flower potful of petroleum; apply the mixture hot, or at a temperature of 130°, also liberally and briskly, with a suitable brush, till every minute crevice is filled with it, and the entire bark saturated. If this work is done well there will be an end of insect life there. If any are left behind it will be evidence of bad workmanship. Others may come from elsewhere in the spring, and take possession of the Vines, and are certain to do so if there are any left on plants, in the soil, in the fissures of woodwork, no matter where, and it is because of this that the cleansing of the house and everything in it should be searching and exhaustive. Let no one lull himself into a state of false security in assuming that if Vines are clayed and tarred, or coated with any other pigment in fashion for the purpose, they will be safe, because insects that emerge from their winter resorts will refuse to crawl up the stems. They will refrain from this when hungry men prefer going without breakfast and dinner because the roads are dirty, and not till then. Dirt is no deterrent of insects; cleanliness, thorough cleanliness, everywhere being infinitely more effectual.

It has been said the soil, especially dry soil, in vineries, affords shelter to insects in the winter. Thousands have been there protected, and come out in spring, to the surprise of owners or managers who have been at a loss to know where the invading horde "sprang from." If the soil is allowed to get dry, as it often is close to walls, and especially under a stage or near a flue or hot-water pipes, it shrinks, forming fissures, and as deep as these are so far will the pests travel and find the conditions they need for passing a few months comfortably. They also ensconce themselves in the loose dry soil near the surface of borders. All such soil, indeed the entire surface, should be removed from insect-stricken vineries, down to where the soil is moist, even if a few roots are disturbed in the process. Then if the soil below is not moist enough—and it is often much too dry—water should be given with no sparing hand, and if at a temperature of 140° it will do no injury whatever to Vine roots, but it will to insects that may happen to be left behind when skimming off the surface soil. It is almost impossible to pour in too much water where the soil has shrunk from walls through drought. Those parts should be quite saturated, and never be

allowed to get dry again. Neglect of out-of-sight places in vineries and other structures amounts to inviting insects to take possession and emerge when they can do any good for themselves and injury to Vines and plants.

Before adding fresh soil in place of that removed from the border, no harm can be done in giving a thick dredging of soot. This acts both as an insect obstacle and Vine stimulant, and if the new soil given is good, and not loose, but tolerably firm, also kept moist through the summer, new roots will take possession of it to the great advantage of the Vines; and, perhaps, the more the old roots are "disturbed," not ruthlessly, but intelligently, cutting back any that may be found shrivelled or decayed to healthy and thicker parts, the greater will be the production of young feeding roots into the soil near the surface. It is quite certain there are many portions of roots on some, if not most Vines, that would be better off than on, and their removal to healthier parts would be followed by a great increase in the number, as well as the quality, of roots succeeding.

What is wanted in the case of most Vines that are not so satisfactory as could be wished is a multiplication of roots for imbibing what the soil contains, or what may be added; but in the absence of fleshy fibrous roots much money may be spent on manures to little effect, these being then denounced as worthless, though in reality they may be amongst the best in the world, but applied under wrong conditions. First afford Vines a chance to produce a mass of active roots, then the food given will be appropriated, and its effect be seen on the foliage, wood, and fruit in well-managed vineries; for all know, or should know, that mismanagement in summer will nullify the effects of the best of soil, the best of manures, and the best of winter work.

MIXED HARDY FLOWERS.

THOUGH hardy flowers are very often unsatisfactory there is no reason why they should be so. Nay, there is every reason for their occupying worthily a prominent position in the adornment of gardens. The simplest method is to plant in wide and long borders, strictly to limit the choice of plants to those which are distinctly beautiful, showy, and if possible, sweet, and to arrange them with discretion. Culturally the borders must have every justice done to them both before planting by thoroughly breaking up the soil deeply and adding a fair supply of fresh material to it; and after planting annual dressings either of soil or manure are of great importance. If no additions are made in the way of plants to the borders a surface dressing of clean soil is as good as anything. If, on the other hand, numbers of plants are annually put in in order to form a distinctive feature at one season of the year, then manure dug or pointed in may form the best method of placing fresh food in the way of the plants. Nothing is better for pointing in among the smaller plants than Mushroom bed refuse. This need not be put in at a greater depth than 3 or 4 inches. For strong growing plants such as Hollyhocks, Phloxes, Pentstemons, &c., cow manure is best, and may be dug in to a good depth.

I have said that hardy plants should be disposed in wide and long borders, and the reason for making that statement is that we naturally expect flowers in these borders at all seasons when they can be had out of doors. We also expect a continually shifting variety of plants with a good deal of overlapping of course, but no doubt one of the charms of the mixed border is the expectation of fresh kinds of flowers coming out continually throughout the season. That being so we must have room, and a wide border is the consequence. But many of the finest out-of-door flowers are of noble proportions as to height and width, and in order to secure due effect with these an extended border is important. Then as to limiting the choice of plants. It must not be supposed that it is meant thereby that the collection should be devoid of variety. Too much cannot be secured so long as the necessary conditions are fulfilled of beauty, showiness, and, if at all possible, sweetness of scent. But what is condemned is the not uncommon practice of picking up all sorts of weedy rubbish so long as it is called herbaceous, and taking up room that could be better filled. Another not uncommon failing with people who plant borders of hardy flowers is that of avoiding the flowers which have been improved and multiplied in variety. For my part I see no harm in making a border gay in spring with Crocuses, Tulips, Polyanthus, Primroses, Auriculas, Wallflowers, and Anemones. These do not

detract from the beauty of distinctly alpine and herbaceous plants which flower with them. In the same spirit I do not exclude from these borders tufts of Pansies, clumps of sweet Pinks and Carnations, Roses of all sections, Chrysanthemums, Phloxes, Delphiniums, Hollyhocks, Pentstemons, and many others grown in large clumps. Of Dahlias the Cactus varieties are especially suitable. These and other kinds for this purpose are best grown, not from cuttings but from divided tubers. These flower more freely, and I imagine do not grow quite so much to foliage as plants from cuttings do, and certainly they pass the winter much better. We have so many good perennial plants to select from that annuals do not occupy much space in our hardy borders. There are, however, a few so distinct and good that we try to find room for them.

As to arrangement, it is very easy to say, Put the tall plants at the back and the smallest at the front, placing those of intermediate sizes in the space between. Such advice rigidly carried out would insure a hotch-potch without character, effect, or beauty. Some hardy plants in addition to the beauty of their flowers are, as regards form, worth cultivating for that alone. Such plants, of course, need to stand in some degree clear of others. *Solidago canadensis*, *Iris ruthenica*, *Spiraea Aruncus*, *Anemone japonica* are examples of this; but there are others, such as the common white Lily, Carnations, *Gladiolus*, *Chrysanthemums*, which ought to be placed very near the front of the borders. A well arranged border may in summer and autumn have plants 3 feet in height growing close to the front edge. Of course, many of the plants are standing perfectly clear, the ground being carpeted with dwarf flowering plants and those which have flowered during the spring and early summer months, while the back of the border is brought to proportion by clumps of tall Hollyhocks, Phloxes, Michaelmas Daisies, single herbaceous Chrysanthemums, &c.

As to colour, if a thoroughly effective border is wanted, it must be arranged so that its effect as a whole may be taken in. It is hardly possible to have too much white. That secured, yellow is of the greatest importance for giving brightness. White and yellow of themselves will make a most effective colour arrangement, and, of course, others, such as red, blue, and secondary shades and tints must be made the most of for changes. For purposes of colouring, *Delphiniums*, Snapdragons, *Tritomas*, *Lupinus polyphyllus*, *Aster bessarabicus*, dark Phloxes, and *Pentstemon*, *Dahlias Juarezii* and *Glare* of the Garden, *Schizostylis coccinea*, *Gladiolus brenchleyensis*, *Agapanthus umbellatus*, *Lilium tigrinum* fl. pl. and *L. umbellatum* are flowers which occur to me as of great value for colouring. Under certain conditions I should not hesitate to employ *Pelargonium Henry Jacoby* and *Clematis Jackmanni*. Meanwhile I might advise that in order to improve a border of hardy flowers do not stick at a sentiment and keep out flowers which, although not strictly herbaceous or hardy, would be found of value if freely used.—B.

ROOT-PRUNING.

THE advantages of root-pruning are many, if intelligently and carefully carried out. We should hear less of barren trees and inferior fruit if the knife were used more at their roots and less on their branches. There are hundreds of unprofitable fruit trees in this country, not because they are bad varieties, nor because the locality or soil is unsuitable, but because they are subjected to cultural operations only calculated to produce gross unfruitful wood, and in many cases canker. If you want a tree to produce wood only, plant it deeply in a rich garden soil, decide to keep it to a certain size and shape, never disturb more than the surface roots, which, of course, must be done once a year for appearance sake; follow faithfully such an irrational practice, and it will not take long to gather the fruit. Who, of any gardening experience, has not seen samples of this kind, and also witnessed the bundles of summer shoots annually cut away to keep the tree within bounds and to its proper shape? It is simply presumption to expect a fruitful tree under such conditions; it is totally contrary both to the theory and practice of fruit culture. For a tree to be fruitful it must have abundance of fibrous roots, and the more numerous these are close under the surface, the better will be the quality of the fruit. Of course we do not object to trees being kept to a certain size and shape, but we do condemn the baneful practice of annually cutting away large quantities of summer shoots, instead of attaining those ends by a judicious course of root-pruning. After a tree has attained the required size, the cultivator should aim at arresting the sap and causing it to accumulate in the formation of fruit and fruit buds; but it is impossible to bring about this desirable state of things if the trees are allowed to drive strong fibreless roots deep into the cold subsoil. It is impossible that roots at such a depth can ever supply food that will

be converted into other than wood buds; and by cutting off the summer shoots we increase their sterility, because we concentrate the already superabundant sap upon fewer buds, thus causing them to break into gross shoots which are not wanted, and which would be little good if they were, for unless carefully handled it would take years to clothe such shoots with fruit spurs.

The cultivator must aim at equal balance between root and branch; in other words, when it is seen that a tree is producing wood at the expense of fruit buds, it is a sign there are too many strong roots; therefore, instead of annually cutting off a quantity of shoots, the tree should be carefully lifted, and the strong roots well cut back. Careful root-pruning will be found to cure the most obstinate cases of sterility, provided it arises from an undue supply of sap; but, of course, it will have no control over climatic conditions of an unfavourable nature, such as late spring frosts, unsuitable localities, or shady positions, only in so far as it enables the trees to form more perfect flower buds.

It requires care and forethought in dealing with old established trees, as, if they have not been lifted for a number of years, there will be comparatively few fibrous roots, hence one half should be pruned one year, and the other half the next, otherwise too great a check may be given. The fact, however, of a tree being old, or of its not being lifted for a number of years, need not deter anyone from root-pruning, for if it be clean and healthy it is certain to respond and reward the cultivator.

Perfect fruit buds and first class fruit can only be formed from the most highly elaborated sap, hence the importance not only of the roots working in a congenial medium, but of the trees being planted far enough apart, and their branches thinly disposed, so that the sun's rays may reach every leaf. The best results are obtained from beginning with young trees. If these are lifted every two, three, or more years, always being guided by the amount and quality of growth the trees make, they will soon become a perfect mat of fibrous roots. Such trees may be lifted without any risk early in the autumn, just as the leaves begin to change colour, with every confidence of their ripening a full crop the following summer—other conditions being favourable. Should the soil be unduly dry, the trees must be well watered after being replanted, especially if it be done in dry weather, otherwise the wood may shrivel and the fruit buds be imperfectly formed. In exceptionally dry weather it is sometimes necessary to give the trees a good watering three or four days previous to lifting, so as to prevent too much soil falling away from the roots. An occasional soaking of water during the following summer and a thick mulching of littery manure will also be very beneficial.—J. H. W.

NOTES ON LILY CULTURE.

ANY information calculated to assist those interested in the cultivation of Lilies will be always welcome, and I have read with interest the notes by Dr. Wallace at page 462, though it does not altogether agree with my experience. In the note in question reference is made to *L. auratum* as a moisture-loving Lily. This is hardly the natural wild condition of this Lily, though this matters little if it be found to answer under cultivation. By far the finest plants of *L. auratum* I have seen were the occupants of Rhododendron beds, where, while enjoying the shade about the base, which I have always regarded as necessary, could not receive much in the way of moisture unless special artificial modes of applying it were resorted to, or the season exceptionally wet, simply because the Rhododendrons with their mass of small fibrous roots would soon absorb all, particularly in hot and dry seasons. What I had hitherto regarded as "sunstroke" in years past has been almost as common with this particular species during the past almost sunless summer of 1888. Surely if moisture was needed we have had it to the full this season, but my experience in Middlesex is very much opposed to a repetition of such a rainfall. The flowers have been destroyed largely. *L. auratum*, *L. platyphyllum*, *L. longiflorum* varieties, and *L. speciosum* have in this respect suffered alike, while I do not see any appreciable difference in the bulbs, which are very good. *L. Humboldtii*, the bulbs of which were quite flabby and shrivelled when the importation came to hand, has done splendidly, far exceeding anything I had expected.

Nearly twelve years ago when at Sydenham Hill we experimented with Lilies in various positions, more particularly *auratum* and *speciosum* vars. The former were planted, some among the Rhododendrons, which occupied steep banks of a greasy clay—the output from the Penge tunnel—which was beneath us. In this the Lilies and Rhododendrons did well. Others were in peaty beds well shaded from the hottest sun by some fine Beech trees. On single stems of *L. auratum* I have counted upwards of 100 flowers and buds. Others were in semi-wild places in the wood, and others still were planted in a bed continually moist though well drained.

Those in the moist beds flowered fairly well the first year, but nearly all the bulbs perished; sufficient proof as we regarded it that moisture was no good to *L. auratum*, especially when compared with the others that flowered so well in the drier positions above stated.

What puzzles me most respecting *L. auratum* is that so many imported bulbs make no basal roots at all, and the majority which do not form these roots must perish as the result, for no new bulb can be formed, hence only a shell is left behind. I fully believe in a cool shady rooting medium, and also planting at fair depth, but I have never planted more than a foot deep. As far as my experience goes, deep planting appears to encourage the growth of stem roots, and in some Lilies the stem bulbs also, *apropos* of which I may remark that I have purposely buried fresh growths of *L. longiflorum* eximium which had made 15 or 18 inches of new growth in transit from Japan, and when lifted, these had formed bulbs along the whole of the buried portion of the stem, and to just beneath the surface, as though they were only 6 inches deep.

This sudden collapse, be the cause what it may, seems chiefly to affect *L. auratum*, while the varieties *platyphyllum*, *virginale*, and *rubro vittatum*, invariably make good basal roots and fine new bulb growth. Especially is this so with *platyphyllum*, which has a far better constitution than the type, and does better under precisely similar conditions side by side. To call this collapse "sunstroke," is, I consider, a misnomer, seeing it has been quite as common this year as last, and that it comes far too gradually; indeed it has occurred to plants in pots in the greenhouse this summer, where sunstroke would be quite outside the question. The first symptoms of the collapse are in the leaves turning yellow, also the buds slightly so. These presently fall with the leaves, then the stem blackens; but if anyone examines the bulbs as soon as the leaves begin to turn, he will find little but decayed matter, and that there had been no basal root action at all. The development of the stem, leaves, and buds up to the given stage has been supported wholly by stem roots. In the case of healthy bulbs, when the main or basal roots exist in plenty, these stem roots materially assist in maturing the blooms, and thereby lessens the functions of the main roots, consequently these latter concentrate greater force in the building up of the new bulb for the next season's flowering.

Dr. Wallace, in paragraph 3, has evidently abundant experience of *L. auratum* decaying, but he appears to attribute it to an unsuitable soil, and recommends deep planting with abundant moisture. For sound healthy bulbs I quite agree with the advice tendered, but what of imported *L. auratum* in a heavy water-logged soil? Does Dr. Wallace find that a greater percentage of these form basal roots under these latter conditions than under the usually accepted method? Latterly, seeing that year by year more imported *L. auratum* failed than all the other Japan Lilies together, in which I include *L. platyphyllum*, *L. eximium*, and *L. speciosum*, I had wondered whether the damage was not done during transit—that is, during the time they are sealed up these deadly germs are at work; at any rate the wreckage is complete when they are unpacked in many cases, and in others occurs after planting. It may be that *L. auratum* is less able to endure the voyage than the others named, and among which failures after planting are reduced to a minimum.—E. J.

THE FILBERT AND COB NUTS.

WITH the exception of the Grape Vine there is no fruit tree with which I am acquainted so much indebted to pruning for rendering it fruitful as the Filbert. I believe that I do not exaggerate when I state that the severity with which this tree is cut in exceeds even that by which the best Grapes are generally obtained. Such severe mutilation would very quickly cause disease and death in a tree less robust and less tenacious of life; but the Filbert endures all for many years, and rarely succumbs, some plantations being quite fifty years old, although other reasons often afford a cause for removing them before that time. Filberts are often met with as a sort of undergrowth to fruit trees of larger dimensions, as standard Apple, Pear, Plum, or Cherry trees; but they are also frequently allowed a plot to themselves, and certainly, where the soil and other circumstances favour their growth, they well deserve a place where they will not be interfered with by other trees.

I believe it is generally admitted that the Filbert and Cob Nuts are importations from the Peninsula or some other district in central or southern Europe, and not a native improvement on the wild Hazel Nut of our copses and woods effected by long and persevering cultivation, as the Apple and Plum may have been. The economical value of the latter fruits being greater than that of the Nut, the desire to effect improvements was, no doubt, more earnest

in their case than in that of the Nut, which was most probably regarded as a luxury. Dismissing that subject, however, I may remark that the same soil and situation in which the wild Hazel is found appears to be the best for the cultivated varieties—namely, hilly stony districts, neither too dry nor too wet, and of which the subsoil is penetrable by the roots of this and other trees. On such a soil is found the wild Hazel, and on such, too, the cultivated Cob and Filbert thrive the best. The aspect does not seem to be of so much consequence, as Filbert grounds are found in declivities facing all directions, not the least productive being those with a western aspect, while plenty having a northern one are equally successful; but all aspects are under this crop, and now and then a plot nearly level is met with. Generally hilly places are put under this crop after having been trenched and part of the stones taken out. The heavy loam of low lands which produce the best Wheats does not appear to answer so well for the Filbert, and a drier position should therefore be selected.

The Filbert and Cob are propagated plentifully enough from suckers at the root, which are generally bedded in some nursery ground for a year or so before finally planting out, and they are headed down to within a foot of the ground, to obtain a series of branches radiating at that height, which are so cut and arranged as to form the skeleton of the future tree. This, when full grown, in some respects resembles a basin in shape, the centre being hollow, and the outer edges about 5 feet from the ground, the diameter being 12 feet or so. Where there is a large number of trees together, and they are carefully planted in lines at 12 feet apart each way, and trimmed as they usually are, the upper surface of the rim of each tree is an exact counterpart of its neighbour, and the eye of the observer passes over the whole in a line parallel with the ground. Each tree is cut as exactly at a certain height from the ground as corn usually is, and the only difference is that the Filberts are 5 feet from the surface, and the stubble only a few inches.

The mode in which the Filbert is trained might, perhaps, be very well copied in the case of other trees. The young tree, as already stated, is cut down so as to obtain a quantity of shoots at less than a foot from the ground, which are so cut as to secure others continuing to spread in all directions from the centre with so little rise that at the radius of 5 or 6 feet their tops may not be higher than at most 5 feet from the ground. This pruning and training, however, is the work of years, and while it is progressing lateral branches pointing in the same direction are left on and encouraged, taking care that whatever young wood is allowed to remain for such a purpose should be neither too strong nor too weak, the former only producing its like, and the latter being too insignificant to expect much from; but of the two extremes the latter is by far the preferable. Some other peculiarities in pruning are also well worthy of notice, and might, perhaps, be copied with advantage elsewhere. It is well known that the Filbert and Cob (both being alike in that respect), push shoots 6 feet long and upwards. These rampant shoots are sometimes situated where a branch is wanted, or where it would be imprudent to remove them entirely; and to cut them back with the knife in the usual way would only be to encourage another of a like kind from the one so operated upon. In cases of this kind the knife is laid aside, and a rough-toothed saw is used to cut through the shoot, leaving it in as haggled a condition as it well can be, and this coarse operation assists in checking the tendency of the same branch to produce other vigorous shoots; while all small shoots are shortened in by the knife in the same way as those of other fruit trees, the portion left rarely being more than 3 inches at any place, and often less in the full-grown tree. Neither are the main and subsidiary branches at all close, the practice being to get a few (what might appear), gnarled, ugly, stumpy branches with a few spurs on equally uninviting to look at; but the practised pruner can tell tolerably well by the appearance of the tree which are fruit-bearing spurs and which are not, although it is difficult to explain how on paper. In general such shoots are small and short-jointed, and about the end of January, if the winter has not been unusually severe, small pink spots will appear, showing through the bud; these are the female blossoms, and form the embryo of the fruit; the male blossoms are expanded, and hang in catkins months before these appear. It is, therefore, better for those unacquainted with this tree not to begin to prune until these tokens of fruitfulness can be seen; at the same time it is not prudent to delay it too long, as they are easily rubbed off, and all prospect of fruit is then gone.

The female blossoms though expanded long before settled fine weather, are, nevertheless, tender, and easily injured by frost, and, therefore, a declivity facing the west is often thought to be the best, as the frosts of spring are often gone ere the sun can shine, and thus they escape injury. Overhanging Apple trees are likewise not altogether without their use, as they afford a little shade and

shelter, so that large breadths of these trees and Filberts are planted together, while in not a few instances there is a crop of Hops overtopping the Filberts for some years; but this latter plan is not considered of any benefit to the Nuts, but is merely adopted to obtain the most from the ground. Gooseberry and Currant trees are by far the most common accompaniments, they being invariably planted to occupy the spaces between the Filberts while these are progressing. Assuming the latter to be planted at 12 feet apart each way, the small fruits might be 6 feet, or if the Nuts are 10 feet apart, the latter would be 5; so that for every Cob or Filbert there would be three Gooseberry or Currant trees, unless the latter or the Nuts were intermixed with standard Apple or other trees, which are often 20 feet or more apart. Generally, however, the ground is heavily cropped from the beginning, and it is by no means unusual to see Currants, Filberts, and Apple trees all growing together, the last overtopping the former two, and scarcely a speck of ground to be seen. It is very rare that a Filbert is seen on grass land, the opinion being that the tree derives advantage from tillage; and, on the other hand, as the Cherry is said to be injured by this, a Cherry orchard is generally laid down in grass. Such is the Kentish custom, and a long course of culture based, no doubt, on practical observations has determined this course to be the best in both cases.

Of the varieties most esteemed by the grower it is difficult to say much, the demand pointing out the kind most proper to grow; but there is little question that the quantity of Cobs now grown far exceeds that of Filberts, and that the culture of the former has been on the increase for many years, whilst that of the latter has been decreasing, few young plantations of these being made. The varieties of both are very limited in number as compared with those of other fruits. Sometimes when a grower has a reputation for fine fruit a local name attaches itself to the variety he cultivates, although in all probability no real distinction exists. However, there are some inferior kinds, and these it would be proper to weed out. Subjoined I give the names of a few, to which, doubtless, others might be added.

COMMON COB.—I believe a much harder-shelled one than this is found in other counties, as the kind now called the common one is the same as Lambert's or Kentish Cob elsewhere. A good Nut, producing excellent clusters, with a large full kernel. I may mention that, for experiment, I once weighed a quantity of average quality, including the husks, as they were, and had them cracked, and then weighed the kernels alone, and these were found to be a trifle more than half the weight of the whole, and therefore the reader may form an idea that they were pretty full. The shell, however, is harder than that of the Filbert and improved Cosford Cob, but the kernel keeps better than the latter, and is equal to it in flavour.

COSFORD COB.—This only differs from the last in being thinner-shelled; as regards bearing it is much the same, and except that the common Cob keeps fresh longer, there is not much difference between the two.

SPANISH COB.—The distinction here is so questionable that it is doubtful if the Kentish and Spanish may not be synonymous. There are also other names, having reference to localities where large quantities are grown, but it is impossible to describe them as being applied to distinct varieties.

RED-SKINNED FILBERT.—This is by many esteemed the finest Nut grown, and for a month or more after gathering is unquestionably so, and most people admire it during that time. It does not, however, keep so well as the Cob, and, as a plant, is less prolific, or, rather, is more tender. A few plants, however, ought to be in every collection.

WHITE OR COMMON FILBERT.—This is more hardy than the last, and bears better; it is also a very good nut.

FRIZZLED FILBERT.—The husk which encloses the nut being fringed at the point has given this plant its name. As a curiosity it has its admirers, and the nut is also good, though not better than those above mentioned; but the peculiarity of the husk gives it a claim to notice.

Besides the above there are many others perhaps with which I am but imperfectly acquainted. One variety is grown for the tint of its foliage resembling that of the Copper Beech, and is called the Purple-leaved. I believe, however, that its fruits are little, if at all, better than common Hedge Nuts, its merit resting solely on its foliage. There is also said to be a Dwarf Prolific of high reputation, and which doubtless deserves notice, but not being acquainted with it I cannot speak of its merits. Possibly, however, other growers from localities equally favourable to the growth of Nuts will give us the benefit of their experience. There is no fruit that I am acquainted with of which the cultivation seems to be confined to so few districts as this. Assuredly the soils and situation suitable for it are more generally to be found than is commonly

supposed, and there seems to be no reason why it should not be tried in many places in which there is every prospect of its succeeding.—N.

SOME REMINISCENCES OF THE SHOWS.

ALL lovers of Roses receive with interest and welcome the annual review of the season as given by "D., Deal," and will join with me, I am sure, in hoping that it may be many years before his valuable presence will be missed from the principal Rose shows, or his great experience as a florist be lost to the pages of the Journal. I should like to add a few of my own reminiscences of two or three of the larger exhibitions, which have been recalled by his article.

Those who have never previously showed at the Crystal Palace must surely have thought, as so many have said before, that there really is no place like it for a Rose show, and except that it is not so accessible as a central London site, especially in getting away on a Saturday night, the N.R.S. are to be congratulated upon the situation of their metropolitan and principal Show. What pleasant greetings take place at these first meetings of the summer campaign! for rosarians are so friendly and courteous, and if one of our number did tell two others, as they walked together up the hill to the Palace, that his dwarf (!) Charles Lefebvres were 10 feet high, I am sure the only point in their conduct that could have been deemed inconsistent with respectful admiration was that they both paid 10s. 6d. entrance fee the next day in order to go 150 miles to show against these "giant dwarfs" in their own home.

The most noticeable feature of this, one of the National Exhibitions, was the cold, not only of the day itself, but also of the day and night before. I should think this was unprecedented. We have had wet Rose seasons before, but never in my recollection such a cold one, and the natural effect of such an inclement time was that the Teas made a very poor show indeed. It has been remarked that Mr. Baker, who regained the amateur trophy, had no Teas at all in his forty-eight, and it will be remembered that he was particularly strong in the year 1879, so that a cold wet season seems to suit him; but it was certainly not in 1881, when he was champion again. Roses were not out on the strong heavy soils, and those who relied much upon their Teas to help them in the big classes were naturally disappointed. These causes would account perhaps for Mr. B. Cant not taking quite his usual high position, but some of Mr. F. Cant's Roses in a higher position were forwarder, and by protecting his Teas from the rain he succeeded in bringing back one of the champion trophies to the eastern counties. Some strong exhibitors—Mr. Pemberton for instance—were not in a position to show in force for quite a fortnight later.

The weakness in Teas caused a noticeable absence of yellow. How is it that Mr. Prince can always show Comtesse de Nadaillac for twelve of any yellow Rose? There was no doubt about his twelve blooms being yellow, but this Rose almost always has more pink and white in it than yellow with me, and yet I have won some medals with it. Souvenir d'Elise, the show Rose *par excellence*, was again conspicuous by its absence. Last year they were all over before the Show; this time, I suppose, they were decayed on their stems. Mine were.

Manchester Show, to be interesting to exhibitors who are not quite in the first class, wants "protection." The schedule is very free trade indeed. There are only two divisions. Any nurseryman or amateur may show in every class in their own division, so that the giants have it all their own way. By this arrangement a better standard throughout is probably maintained, but the actual number of entries is lessened I should think. Messrs. Dickson of Newtownards showed some pluck in exhibiting from such a distance, and the stand of these enterprising and successful raisers of new Roses was very interesting. Their new H.P. Caroline D'Arden came in for much admiration and criticism, but I think I must leave an account of new and notable Roses as seen at the Show for another letter.

The adventures undergone by an exhibitor in his journey to the Wirral Show, as ably related by him some time since in the Journal, made me congratulate myself that I shirked that undertaking—a very serious one from my abode—at the last moment. But there were trials and disappointments also at Darlington. In that one former holder of the amateur championship, as related by "D., Deal," had a private thunderstorm of exceptional violence all to himself, and another, on the very spot, was prevented by the lateness of the season from exhibiting at all.

My own adventures on the road to Darlington, though of no moment to the Show, were sufficiently trying. It was really not more than two minutes that I and another exhibitor left our boxes out of our sight at Doncaster, where we had to change; but during that time a wretched

porter had wheeled off both our charges, and huddled them into a van. We could find neither him nor them at first, but at last we discovered them, and counted the pile as best we could by the dim light of his lamp. The number was correct; they seemed all right, and we failed to notice that he had positively placed one of each of our boxes exactly upside down. No sixpence which I ever spent did I afterwards lament more than that which I left in his unworthy palm. Absolutely upside down did those two boxes travel all the way from Doncaster to Darlington. I need not tell those who believe in the general perverseness of things that mine was *the* box of my lot—a carefully selected twenty-four, with all my best blooms in it—on which all my hopes rested. But I was spared the actual sight revealed when the box was opened of sodden moss and dirty Roses hopelessly intermingled, for my very kind companion in misfortune, who took charge of my boxes for the night, had endeavoured with great good nature to re-arrange the contents of the box as far as possible by the time I arrived on the ground.

I am very much indebted to my fellow passenger for his kindness, and I remember another example, some years ago, of the friendly feeling which happily prevails among rival rosarians. An exhibitor, who is particularly noted for his skill in "getting up," was preparing his box at one of the national shows in an important class (to us), in which I had also entered. I thought that my blooms, "in the rough," so to speak, were better than his were, but my skill in arrangement, &c., was as nought compared to his, and to my half-humorous suggestion that he should set up my blooms as well as his own he actually consented, and in a very short time their appearance was immensely improved. For once in a way Dame Justice had both her eyes open: we got equal first. I do not know what I should have done if I had beaten him. I may also say that the fortunes of my capsized Darlington box after passing the ordeal of judgment were such as to make me less squeamish afterwards about a slight jerk or tilt to boxes in transit.

The professional exhibits at Darlington seemed to be generally below par, though Messrs. Harkness appeared to hold a strong lead in H.P.'s. A number of stands were exhibited in the class for twelve Teas (nurserymen), but it goes without saying that they were poor in quality, and also that the blooms which won the amateur Jubilee trophy were "tall" indeed.

I think that, on the whole, thin-petalled Roses did not do so well as might have been expected in such a cold wet season. It is true that Prince Camille de Rohan, which I had almost discarded, re-appeared in strong force, and was to be seen in nearly every stand at the Crystal Palace; and that a Rose which I have long given up, and never thought to see exhibited anywhere—viz., Duchess of Edinburgh was to be seen in the winning seventy-two. But still I was disappointed with many of those Roses which will not "stand" in hot weather, and might, therefore, be expected to be shown in better order this year.

I happened to have a good many plants of Thomas Mills, H.P. Now, thought I, Master Thomas will really come to the fore, and with his glorious colour and perfect shape will be *the* Rose of such a season as this. Nothing of the sort. A considerable number of the plants did not bloom at all, and when I stopped the shoots at 5 (not 10) feet high, they did not bloom in the autumn, and such flowers as I did have were considerably inferior to those of hot seasons. Oh, Thomas Mills! how grateful my friends will be for your strong plants.

The Dukes of Edinburgh and Teek, which I should reckon among thinnish Roses, did certainly do a little better than usual, and so perhaps did Prince Arthur, but I failed to see any improvement in the way of lasting for exhibition purposes in Général Jacqueminot, Mrs. Harry Turner, or Dupuy Jamain, for this last is a had one to stand with me unless it be grown very strong.

The National Rose Society's catalogue gives Fisher Holmes as a thin Rose, but in my experience it always stands well. The H.P.'s, which I found to do unusually well and really seemed to like the weather, were Duchesse de Morny especially, and Marie Finger and all her race.

Thick petalled, hot-season H.P.'s, such as Comtesse de Serenye, Marie Rady, M. Noman, Pierre Notting, Reynolds Hole, and all the very light ones, certainly failed as conspicuously as might have been expected. The only exception I remember was a bloom of M. Noman, which got the shelter of a bell-glass. It turned out the best specimen I ever saw, and won me a medal.

Of exhibition Teas I should reckon Anna Ollivier, Francisca Kruger, Madame Lambard, Marie van Houtte, and Rubens as comparatively thin-petalled. All of these did do better than other Teas, with the exception perhaps of the first, Marie van Houtte and (with me) Francisca Kruger being the best.

Thick-petalled and shy-opening Teas, like Comtesse Panisse, Jean Dueher, Etoile de Lyon, Marie Guillot, Madame Willermoz, and Souvenir d'Elise, were naturally scarce; but Madame Willermoz, by the help of toilet arts, made a handsome appearance occasionally, and Etoile de Lyon, strange to say, opened better with me than it did last season.

I have witnessed during the past week the lifting of some Roses on Manetti, which had been planted just three years and had grown and bloomed fairly well, though not as well to my mind as they would have done on the Briar.

The Manetti roots were alive, and that was all that could be said for

them. They appeared to have made no growth during the past season, and were black, brittle, and nearly fibreless. Each Rose, however, had roots of its own of a very different character, brown, tough, very fibrous, and evidently full of growth, and anyone, I think, on seeing them would say that in two more years the Manetti roots would be dead, and the Roses would be on their own roots alone.—W. R. RAILLEM.

NOVEMBER AND DECEMBER PEARS.

[A paper read by Mr. George Bunyard at the Horticultural Club.]

IN treating of these delicious fruits I feel that I can add but little to what is already known, but a club friend of mine said "Never mind, hammer away at the truth, and it will do some good." On this assurance I proceed. In my paper on "October Pears" in 1887, of those then named as ripe many are not yet in use, showing how greatly the fruit is influenced by the summer weather, and, again, the climate. A little further north puts the fruit back two or three weeks, while a warm August will forward Pears, so that it is not unusual for January and February varieties to ripen in November. A warm cellar or fruit room will also bring the later Pears earlier; one year, therefore, is but little guide to the ripening season of another.

In glancing over other leading nurserymen's lists I find Marie Louise, Durondeau, Emile d'Heyst, Thompson's, Beurré Hardy, Beurré Superfin, and Beurré Bosc there treated as November Pears, which with us have already been placed as October sorts. None of these were ready early in November. Among the remaining thirty the following are fair and remarkable for cropping heavily, and cannot be dispensed with in a collection, as they frequently bear when those in my special selection are not fruiting. These are Van Mons Léon Leclerc, of refreshing acidity and very juicy; Beurré Diel, of rich flavour, but apt to be gritty; Glou Moreau, rather watery and cold, though sometimes Al from a warm wall; Général Todleben, very large, but not often first class; Duchesse d'Angoulême, rather coarse, but generally fertile; Marie Louise d'Uccle, a good bearer and a hardy sort for cold soils, sometimes good; Nouveau Poiteau, very large, melting and delicious, though somewhat pasty. It is, however, a free bearer, and if taken before too ripe is often first rate. It is green in colour when matured, and apt to decay at the core. Passe Colmar, a fine wall Pear, most prolific, but has a sugary, clogging, Colmar flavour that I do not admire. It, however, is in season for a long time and a sure bearer. Beurré Bachelier, very large and fine on a wall and on Quince stocks, must not be kept long or it becomes insipid. I have eaten this of first quality. Triomphe de Jodoigne is again a remarkable cropper and of large size, but has that cold watery taste which is not approved. It is yet of value as a certain bearer. Alexandre Lambre is a sweet Pear and a great bearer. Among the little known, newer, and not yet fully proved varieties are Beurré Baltet, which I have eaten as good as Marie Louise; Beurré Dumont, very rich flavour; Vineuse, large and prolific, sometimes very good; Madame Leroy and President d'Osmonville (two which came into prominence at the 1885 conference). All these will probably require a warm situation or a wall. Fondante Shirriott, a valuable Pear of the Passe Colmar style, most prolific, is likely to prove a valuable addition.

I now come to the best of winter Pears. Baronne de Mello, a handsome small russety fruit of great excellence; Doyenné du Comice, the king of all Pears, and yet unapproached, good either from an open tree or as a wall fruit; Beurré d'Arenberg, most fertile and of delicious full flavour, very prolific, but only to be attempted in warm soils; Conseiller de la Cour, a large long fruit, very prolific, of a rich sub-aromatic flavour—this does well in cold soils, and is a good grower; Knight's Monarch, one of the most valuable, as it lasts three or four months in a season. I consider the sugary and aromatic Bergamot flavour blended in this variety most refreshing and delicious. It succeeds as an open tree or on walls (on the Pear by preference). It must be double-worked upon the Quince. It has a habit of casting its fruit before it is fully ripe, but its virtues condone this fault.

Winter Nelis is one of our best winter Pears. In the south it is a December variety, and if from open trees is often ripe in November, while from a wall it keeps longer, even till February. It has a full Pear flavour, sweet, juicy, melting, rich, and delicious. It is tender on cold soils, and is worthy of the best south-west wall that can be found for it. Zéphirin Grégoire is a delicious melting fruit about Christmas, and a good bearer, rather small. Beurré de Jonghe is a deliciously flavoured kind, and will keep until February. It is, however, a slow grower, and seems to require the Pear stock to make a tree. Suffolk Thorn is most distinct in its aromatic and delicate flavour. This is rather small but of the first class. Seekle, small and delicious.

This being of a Gooseberry size, can be put into the mouth whole, and thus we get all the juice and aroma. Much flavour is lost in peeling off the skin.

I have now gone through my special selection of ten varieties, and in passing I would condemn the Brockworth Park, or Bonne d'Ezée. We do not want crisp flavourless Pears for dessert. Urbaniste is delicious, and has a peculiarly rich musky flavour. It bears, however, so sparsely that we have long discarded it. The standard of excellence: I take to be such Pears as one could peel and offer to an invalid, easily digested, refreshing to parched lips, and making a welcome change from the kitchen nick-naeks.

Root-pruning is absolutely necessary to get first-class fruit of clean appearance, good colour, and size, and feeding must be carried out liberally. The Rev. W. Wilks' enormous Pitmastons at the Conference were of most delicious flavour and devoid of coarseness and watery juice, proving that Pear roots have the digestion of an ostrich, and a chemical laboratory equal to the occasion. Much stress has been laid on the reduction of sorts. In my opinion this may be carried too far, as Pears of good quality, if not first class, are better than none at all. I would advise such sterling varieties as those in my special list to be planted in many aspects and situations in duplicate to prolong their season. The second Conference at Chiswick proved again the excellence of the Quince stock for Pears, but in soils that are very sandy or dry trees on Pear stocks can be relied on to produce good fruit if attention is paid to culture, and the roots kept within solar influence by root-pruning and lifting, with efficient mulching in June.

Mr. Wildsmith, in his recent paper at the Conference, named twenty-five varieties as the minimum which would keep up a supply for a family, and finds himself in a difficulty to supply from twelve only. Pears are sometimes kept in too cold a place, when they ripen imperfectly, and the chemical changes which take place on maturation are arrested. Mr. Wright at the Conference related how he ripened some Josephine de Malines by placing them on the pipes of a greenhouse in a box, and this hint might be followed by those who want to fill a gap in their supplies. Stewed Pears are being increasingly appreciated, and in these days, when doctors forbid pastry, are very useful for dyspeptics. The best for early use are Gratioli of Jersey, Gilgil, and General Todleben, and also Triomphe de Jodoigne; while for later use, Catillae, Bellissime d'Hiver, and Uvedale's St. Germain, *alias* Belle Angevine, will be useful. I hope you will excuse this digression, that I may call attention to them.

FORCING LILY OF THE VALLEY.

I HAVE taken your Journal for a long time and found much pleasure in reading it. One of your correspondents writes in the issue of the 8th of November that the Lily of the Valley is one of the most difficult of all plants to force in midwinter, and that the forcing appliances in most private gardens are not such as to be able to accomplish it satisfactorily. From the middle of December you can see in all the flower shops in Hamburgh, Berlin, Vienna, &c., any quantity of Lily of the Valley, each spray bearing from eight to fourteen flowers, which have been forced in market-gardens. It is the most profitable business during the months of December and January; sometimes it happens the amount forced in these two months is more than the demand, therefore the price is less than two months later (in February and March).

The arrangements of the market gardeners for forcing purposes consist mostly of stone boxes 3 feet broad, 1 to 2 feet deep, just above the hot-water pipes. The bottoms are made of iron bars covered with slate, then they are filled with about 6 inches of sand. The crowns are then planted in lines, well watered, and covered with glass lids. To keep out the light these must be covered with paper or mats.

The temperature must always be kept at 70°, rising to 90°. After three or four weeks, sometimes sooner, the plants begin to flower; then the glass is uncovered, and later on the lids are taken away altogether to harden the plants. When the first buds begin to open ten to twenty crowns are planted together in 3 to 5-inch pots, put in a light place, and after perfect development are brought to the market.

In private gardens these arrangements are seldom to be found, although Lilies are required to flower at Christmas. One way is in the propagating pits; another is to place over the hot-water pipes or boiler a wooden box with holes in the bottom, filled with 6 inches of moss to keep the air moist; in this the pots containing the crowns are plunged, or you can put sand on the moss and the roots in this, and when they begin to flower take them out and place them in pots.

Taking all together we do not consider the Lily of the Valley a difficult flower to force in midwinter if we have ripe crowns and a warm place in one of the houses. Great care must be taken that the heat and moisture are proportionate.—MILDE, *Oeveljonne, near Hamburg.*

WINTER CUCUMBERS.

ALTHOUGH autumn-raised plants show a disposition to bear freely, they should not, nevertheless, be allowed to swell more fruit than is necessary to meet the demand. All superfluous fruits and flowers should, therefore, be picked off as soon as they appear. Keep the shoots sufficiently thinned and pinched to prevent crowding. Allow a little front and top ventilation on bright mornings as soon as the thermometer registers a temperature of 75°, allowing it to run to 80° before increasing the ventilation, the object being to secure a sturdy growth in the plants. From Christmas to the end of March is the most critical period in the year to maintain a good supply of Cucumbers. Hence the necessity of getting the plants in the best possible condition for the work which they have to do during the time indicated. If bottom heat is supplied by means of hot-water pipes, and the plants are growing in narrow, shallow, and efficiently drained borders, copious supplies of clear tepid water should be given at the roots three or four times a week, more or less frequently, according as the weather is bright or sunless. If a surface-dressing of Beeson's manure be given once or twice a week before water is supplied at the roots it will prove beneficial.

The amount of atmospheric moisture to be distributed in the Cucumber house depends entirely upon the condition of the plants and the weather. Severe weather means severe firing, with a corresponding increase in the distribution of tepid water through the syringe over the plants and in the house generally, morning and afternoon, as much with a view to promoting a genial temperature as keeping the plants free from the attacks of red spider. In short, a humid rather than an arid atmosphere should be aimed at. In dull mild weather, when but little firing is required to maintain a minimum temperature of 65° to 70°, no moisture should be distributed in the house other than that arising from the application of water at the roots, otherwise mildew would be likely to attack the plants. In this case the affected leaves should be dusted with sulphur while damp, and a rather dry and airy atmosphere be maintained for a few days. Fumigation with tobacco paper a couple of evenings in succession will make short work of aphides.—H. W. WARD.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the General Committee of the above Society was held in "Anderton's Hotel," Fleet Street, on Monday last, December 3rd, at 7 P.M. The President, Mr. E. Sanderson, occupied the chair, and there was a full attendance of members, including Messrs. R. Ballantine, Wm. Holmes, J. R. Starling, E. C. Jukes, G. Stevens, L. Castle, G. Gordon, C. Harman Payne, R. Dean, C. Gibson, Newton, Bevan, Rundell, &c. The meeting was a somewhat busy one, not the least important of the proceedings being the election of thirty new members, bringing up the total to 630. It was stated by the Hon. Secretary that satisfactory arrangements had been made for the annual dinner of the Society to be held in "Anderton's Hotel" on December 13th next, when a large attendance of members and friends is expected; among them Sir Lewis Pelly has promised to be present. A selection of music will be given under the direction of Dr. J. F. Haskins by Miss Mary Belval, Miss Ethel Winn and Messrs. J. Bartlett and Franklin Clive.

Mr. C. Harman Payne stated that he had received letters from numerous correspondents abroad in reference to the catalogue and the Society, including communications from Bordeaux, Toulouse, New York, and Constantinople. Some discussion followed respecting the terms upon which foreign members should be elected, and it was resolved provisionally that the subscriptions for America should be one dollar per annum, for France five francs, and Germany four marks. Mr. Payne was, however, requested to draw up a definite scheme to be submitted to another meeting. The challenge trophy offered to societies at the Society's Royal Aquarium Show was also considered, and it was finally decided that it should take the form of a salver or shield, upon which the name of the winning Society could be engraved each year. Messrs. Sanderson, Jukes, and Ballantine were commissioned to procure an article of a suitable character.

Mr. Holmes observed that deputations from Hull, York, and Leeds had waited on him at Sheffield in reference to the provincial show of next year, and that an informal discussion was held with the

two former by himself with Messrs. Ballantine and Castle. Intimation had also been received from Derby and Brighton to the effect that those societies would be glad to enter into communication with the National on the same subject. A question was asked respecting the Sheffield Show, and Mr. Holmes in replying said that it appeared likely that the financial results would be very satisfactory, as it had been largely attended, and in regard to the Show itself he remarked that the only deficiency was in the open classes, which he attributed mainly to a lamentable want of pluck on the part of both the northern and southern exhibitors, who seemed to be equally afraid of each other. He thought Mr. Packman, as an admirable exception and a representative of the south, deserved much credit for entering the competition.

Another matter brought before the Committee was the proposition as to holding a centenary celebration of the introduction of the Chrysanthemum into Europe. It had originated in a letter addressed by Mr. Holmes to one of the daily papers, and on the occasion of the Chrysanthemum Show at the Crystal Palace a meeting was held at which a resolution was passed approving of the idea, and requesting the National Society to undertake the scheme. It was thought undesirable to attempt it next year, as the time would be insufficient for carrying out all the details on an extensive scale. The following year (1890) would, moreover, be the centenary of the introduction of the plant into England. After some discussion Mr. Gordon proposed that it be referred to the new Committee, to be elected in January of next year, as he thought 1890 would be the best time for the celebration, especially as something on a large scale was announced to be held in Edinburgh next year, and a somewhat similar fête was being arranged for Ghent.

A letter was read from Mr. Doughty, Angley Park Gardens (which was also sent to this Journal last week) proposing that a conference should be held on the afternoon of the annual dinner. The general opinion was, however, that there would not be time to make the necessary arrangements, and on the motion of Mr. Dean, seconded by Mr. Rundell, it was resolved that a conference should be held in conjunction with the Society's January Show in the Royal Aquarium, a sub-committee, comprising Messrs. Lewis Castle, George Gordon, and C. Harman Payne, being entrusted with arranging a programme.

IMPROVED PRIZE CARDS.

IN your report of the Birmingham Show the description given of the improved prize cards used applies in every particular to the class cards used at the Hull shows, where for the last four years the names of the exhibitors, the entry and class numbers, as well as the description of the exhibits have been printed instead of written, as is usual at most shows, so that after the awards are made and the cards turned, all particulars appear "in print" on the front, no writing whatever being necessary, all that is required being to affix the adhesive labels indicating the prize in the spaces prepared for them. The plan is more costly but a decided improvement on the old method of writing, but is a great saving of time at a busy period, and reduces the risk of mistake to a minimum.—EDW. HARLAND, *Hull*.

CHRYSANTHEMUM FABIAN DE MEDIANA.

IN Scotland this Chrysanthemum has been grown and shown in splendid condition, and though I have seldom seen it fit to be shown as a Japanese Anemone, it proves to be a real typical Japanese bloom, in form and size resembling Duchess of Albany. The vexed question is, Why this variety cannot be staged as a Japanese, or Japanese Anemone, like Triomphe du Nord, which can be shown as a reflexed or Japanese variety. I would like to hear what some of your able correspondents have to say on this matter, as I am anxious that exhibitors and judges should know how this variety is to be treated when shown as a Japanese bloom, and not in the Anemone class.—J. W. MACHATTIE, *Newbattle Abbey, Dalkeith*.

CHRYSANTHEMUM BLOOMS DAMPING.

ALTHOUGH I have been a grower of Chrysanthemums for a number of years, the present season is the only one that I have experienced any difficulty with them as regards damping of the blooms. But it must not be supposed that this is my first experience with the subject, as I have several times previously seen collections badly affected, and had conversations with the growers as to the probable cause of it.

Most cultivators are of opinion that damping in the flowers is caused by overfeeding the plants in the autumn when the buds are set, and up till the time the flowers commenced showing colour. After very careful observations, I am convinced that this is the principal if not the sole cause of the trouble, and if I am not mistaken those persons who use sulphate of ammonia freely have the greatest proportion of damped flowers. I am not alone in saying this, as several good growers in this neighbourhood are of the same opinion. It is no doubt an excellent manure, but used in a season like the present I think it causes too great a flow of sap in the already overcharged stems. Hence the mischief which follows. Of course I am alluding to Chrysanthemums grown for exhibition, and the fewer the blooms a plant is allowed to carry the more danger there is of damping.

My plants only suffered from this in a slight degree, and I will now give the names of those that were affected. Fair Maid of Guernsey, Belle Paule, Edouard Audiguier, Duke of Berwick, and Empress of India. None of these became affected to any great extent, but I think it was because I took prompt measures to stop it, and I will now endeavour to explain how I treated the plants. On looking over them one morning the last week in October, I was dismayed to find a beautiful

bloom of Empress of India, about three parts expanded, with a quantity of brown spots on most of the lower petals, just as described by Mr. Molyneux in his book, page 77. In twenty-four hours these had increased in size considerably, and it was quite evident the affected petals had begun to decay. This was very disappointing, and I felt quite at a loss to know what to do. The house was dry, hot-water pipes fairly warm, thermometer standing at 50°. There could be nothing wrong in the atmosphere. Suddenly it occurred to me that there might be too great a flow of sap to the flower, as the plant had been liberally fed and the leaves were large and of good substance. Acting on this, with knife in hand, I took an upward cut nearly half through the stem of the plant, just above the first break. About a foot higher up I made another cut on the opposite side; in addition to this I allowed the soil in the pot to become rather dry, and when it was necessary to apply water I put a piece of lime about the size of a walnut in two gallons of water, and when dissolved I gave the plant a good soaking. This was repeated every time water was required, and the result was most satisfactory. The development of the flower was not hindered in the slightest, but damping was entirely stopped, as I did not observe a single floret go wrong afterwards. This has been my treatment with each variety affected, and in every case I have been quite satisfied with the result.—F. HOPKINS.

Now the shows are over, and anxiety on the part of exhibitors greatly lessened, I hope we shall have some discussion on the most important points in the cultivation of this beautiful autumn flower. Damping has been very prevalent this autumn, and already useful notes have been contributed to this Journal on the subject. After nearly a year's labour and care it seems hard to lose fine exhibition blooms a few days before the date of the show. To steer entirely clear of this evil every season, will, I am afraid, be almost impossible; nevertheless, experience and watchfulness may do much to diminish it. That it is worse some seasons than others is undoubted, notably the present one. Unripe wood with overfeeding is, no doubt, one cause, but I think atmospheric conditions have also something to do with it. I had one fine bloom of Belle Paule among others nearly open when we had some heavy rain and local fogs in this district, which in two or three days caused nearly half the florets to damp. I removed them, and then we had a week of fine weather, but no more florets damped, although the plants remained in the same position, subject to the same treatment, except having a little more air. Some varieties damp more quickly than others, Val d'Andorre being the worst in that respect with me. Taking the buds at the proper time prevents damping somewhat. Of three plants of Golden Dragon I only secured one crown bud at the right time. This bloom remained quite fresh, while others on the same plant, and the other two which were not taken at the proper time, damped as they opened.

KEEPING THE BLOOMS.

It is necessary sometimes to keep the blooms fresh for a time, as some of our exhibitors can testify. Different methods are resorted to, but having dry lime in the shed where the plants are placed certainly struck me as a capital idea when I read Mr. Tunnington's paper on "Chat About Chrysanthemums" in the Journal. It is well worth trying, and no doubt will be by some next autumn. I quite agree with Mr. Doughty, page 489, that some further discussion on the respective papers read by Mr. Tunnington and Mr. Molyneux at Sheffield would be highly beneficial, the two most important matters being the proper time and manner of striking cuttings of the incurved section and wood ripening. These two points are, I believe, not thoroughly understood by some cultivators.—G. GARNER, *Amberwood Gardens, Hants.*

CHRYSANTHEMUMS FROM AMERICA.

At the present time there appears to be more good Japanese varieties of Chrysanthemums sent to this country from America than from any other source, and all these are more or less characterised by a stiff sturdy habit of growth. At the Floral Nursery, Maidenhead, I saw some new varieties in flower a few days since, some of which promise to make good distinct exhibition sorts. The plants only having been imported late this season were small, but the flowers were comparatively good. Leopard, mauve spotted with pure white; Thomas Cartledge, orange, incurved florets; Minnie Palmer, creamy white; John Thorpe, rich deep lake; J. Collins, coppery bronze; Elizabeth Bliss, amaranth shaded violet; George Maclure, purple shaded amaranth. These appeared distinct both in colour of flower and foliage.—H. D.

CHRYSANTHEMUMS SUITABLE FOR ARRANGING IN VASES.

At this time of the year we are generally treated to abundance of Chrysanthemum literature, which is read with a keen relish by all true lovers of the autumn queen. The names of the flowers in winning stands, which are published, are closely watched. New varieties noticed at shows or recommended by well-known experts are carefully noted down. Lists are made out of those varieties intended to be grown for next season's campaign, and hopes run high concerning the victories to be achieved during the coming year. All these things are necessary and desirable for growers of Chrysanthemums for exhibition purposes; but as there are many others who grow their plants principally for supplying cut flowers for floral arrangements, for which purpose small sprays of light and elegant flowers are the most effective, I have therefore arranged a list of those varieties found most useful for such purposes. Very few incurved varieties are suitable, because when grown to a

sufficient size to bring out their true form they are too large except for specimen glasses or filling in the bases of larger ones, and even in such positions two-thirds of Chrysanthemum lovers would prefer the wavy flowing outlines of the Japanese varieties. Indeed so extremely varied is this section both in form and colour, that it embraces nearly all the best varieties suitable for the above named purpose. The plants should be grown as bushes, some of the shoots being partially disbudded, just enough to prevent the flowers having a crowded appearance, while others should be left without any thinning out, so as to supply useful sprays with half opened buds clustering around the central ones. Such shoots as these are always effectual when well arranged, but some varieties of Japanese are more better adapted for the purpose than others, on account of their thread-like petals, and also in consequence of the length of the footstalks of the flowers formed around the central one. Where the footstalks are short, when fully expanded, the central and lateral flowers form a solid mass, which, it is needless to say, is not the kind of material for forming elegant arrangements.

Japanese.—Baronne de Prailly, Belle Paule, Madame B. Rendatler, Bouquet Fait, Chang, Cœur Fidèle, Cossack, Duchess of Albany, Ethel, Fair Maid of Guernsey, Fernand Feral, Fimbriatum, Garnet, Gold Thread, Jeanne Délaux, Lady Selborne, Le Spectre Toulousain, Meg Merrilies, Madame de Sevin, Mdlic. Lacroix, M. Moussillac, Roseum superbum, Soleil Levant, Thunberg, Triomphe de la rue des Châlets, and Madame Desgranges.

Reflexed.—Golden Christine, Peach Christine, Chevalier Domage, Cullingfordi, Julia Lagravière, and Progne.

Anemone.—Acquisition, Fleur de Marie, Duchess of Edinburgh, Mdlic. Cabrol, Marguerite Villageoise, Sœur Dorothée Souille, and Souvenir de Lardenne.

Incurved.—Aimé Ferrière, Angelina, Antonelli, George Glenney, Mrs. Dixon, Lady Talfourd, Lady Hardinge, Le Grande, Miss Hope, Mr. Gladstone, Mrs. G. Rundle, and Refulgens.

Pompons.—Bob, Cedo Nulli (white), Cedo Nulli (gold), Cedo Nulli (brown), Duir-Duir, Gold Button, Hélène, Maiden's Blush, Marabout, Miss Wheeler, Mrs. Bateman, Prince Victor, Sophy, St. Michael, Sunset, Rose Trevenna, and Trophée.—H. DUNKIN.

NEW AMERICAN CHRYSANTHEMUMS.

A BLOOM has been sent to us of a variety named Mrs. Alpheus Hardy, for which an American firm of florists is said to have given 1500 dollars, or about £300. The specimen we have seen must be an exceedingly poor example of the variety, for it resembled a small reflexed white Japanese with flat florets, and such as would be scarcely admissible in a third-rate stand at an English show. The papers on the other side of the Atlantic, however, sing its praises in unstinted terms. Miss Emily Louise Taplin in the *American Florist* thus refers to the variety as shown at the Orange Chrysanthemum Exhibition in New York on November 8th:—"The star of the Show was the much-heralded 'Mrs. Alpheus Hardy,' unquestionably the most unique introduction of recent years. One might say the most unique introduction in the entire list of Chrysanthemums without being far out. It is a large globular flower, long-petalled like the Japanese, yet in regularity of form resembling the Chinese type. In colour purest white, free from faintest tinge of colour, and, most remarkable feature of all, the backs of the petals are covered with long silky hair. The effect is indescribably strange and beautiful, it can be likened to a white ostrich tip, and nothing else. One can see at once what an acquisition this must be to the trade. Its keeping quality is as yet unknown, but the texture is thick and firm. It was a lovely sight to see these flowers resting on a bed of Adiantum; perhaps the only Chrysanthemum which does not become coarse by comparison with delicate Ferns. This flower received special honours. The Committee reported on it thus:—'New Chrysanthemum Mrs. Alpheus Hardy your Committee consider is the most remarkable acquisition in the way of new and beautiful plants that has been introduced in recent times.'"

One of the reporters in a New York daily paper, however, appears to have acquired a confused idea respecting the plant, for it is thus noted:—"A novelty will be the exhibition of the Mrs. Alpheus C. Hardy Orchid, an entirely new variety imported from Japan. It is believed that the owner has the only specimens of this wonderful Orchid in the world. He has carefully bred and propagated them until he now has in his conservatories over 5000 specimens. The flower is an exceedingly quaint and peculiar one, exactly resembling a white ostrich tip. Next May these wonderful flowers will be on the market."

Other varieties are mentioned as of superlative merit, the following remarks occurring in one of the reports:—"Too much cannot be said in favour of the new Chrysanthemums exhibited by Mr. William Barr. Mr. Wm. Barr is a wonderful crimson, incurving petals lighter beneath. Peter B. Mead is perhaps the most remarkable golden yellow, with long tubular petals. Sunset is what its name implies, glorious yellow shading into orange and red. Mrs. Carnegie and Miss Alice Brown are more fine ones. Mr. Barr's exhibit was of remarkable beauty all through; there could be no question of its superiority."

A TALK ABOUT CHRYSANTHEMUMS.

THE correspondent of a local paper has, it appears, been "interviewing" C. E. Shea, Esq., of Foot's Cray, whose gardener, Mr. Paekman, has exhibited Chrysanthemums with a considerable share of success this season. The substance of Mr. Shea's replies to his interlocutor's numerous questions was as follows:—

"We exhibit principally in the Japanese classes, for the reason in

the first place that I think that section far more beautiful than the stiff and formal incurved. However, that is a matter of taste. But, beyond that, artificial dressing of the blooms is universally resorted to in the incurved section, and no gardener not resorting to this device, but staging his blooms as grown, would have the faintest chance of securing a prize. An expert dresser can with inferior win against superior flowers. This does not seem to me to be horticulture. However, the practice is so universal that the only practical protest against it is not to encourage showing in this section. Therefore we confine ourselves almost exclusively to Japanese. Generally Japanese are exhibited as grown. Lately there have been indications of attempts to dress this section also, but in my opinion such attempts only serve to detract from the natural grace and wild beauty of the true Japanese flower, and the practice will not probably find many imitators.

"Last year we grew for show purposes 160 Japanese, sixty incurved, forty reflexed, and eleven Anemones, in all 271 plants. This year we have slightly increased our force. Such a small number tells greatly against us in open competitions against the large establishments and nurserymen throughout the kingdom. Many private establishments grow from 600 to 1000 and even more plants. One nurseryman grows for show purposes alone 2500 plants in addition to his ordinary stock. With a small stock every plant must be made to do its duty. Moreover, when the best blooms are cut for the earlier shows it is very difficult with so small a stock to sustain one's form at later shows.

"Next year will be the centenary of the introduction of the Chrysanthemum, or at least of the large flowering kinds, into Europe, and I understand that steps are being taken to mark the event by a grand Chrysanthemum Fête or Festival. I should think that a combination of the shows of the National Chrysanthemum Society and Crystal Palace at the latter place would be the best form for the celebration to assume. The National Society's Show has quite outgrown the Aquarium. As you know, the Chrysanthemum was cultivated in China and Japan for centuries before its introduction into Europe, and our best new varieties still come from these countries. The earliest authenticated record of the flower in Europe is by Breynius, who in 1689 speaks of a small flowered variety as growing in Holland. It was in 1789 that M. Blanchard, of Marseilles, introduced the large flowering varieties. Next year, therefore, will, by a coincidence, be the bi-centenary of the small and the centenary of the large varieties. Of late years the enterprise of our leading nurserymen has resulted in the introduction of some splendid novelties from Japan and China. The size now reached is extraordinary, some of the more loosely growing varieties, when extended, measuring over 10 inches. Of late introductions in Japanese I consider the best to be Avalanche, Marsa, Florence Percy, Edwin Molyneux, and Mr. H. Cannell. For the first three we received first-class certificates at the Crystal Palace Show last week.

"As to the best varieties to cultivate for show purposes, one cannot go far wrong in accepting the list of varieties recently put forward by the Committee of the National Chrysanthemum Society. I should give, in addition to the novelties before mentioned, the leading varieties thus: Japanese—Fair Maid of Guernsey, Meg Merrilies, Baronne de Prailly, Comte de Germiny, Belle Paule, Marguerite Marrouch, Thunberg, Boule d'Or, Japonaise, and Mdle. Lacroix, not to mention many other equally good varieties. Among the Japanese reflexed I should give the first claim to Elaine, Maiden's Blush, La Triomphante, Val d'Andorre, William Holmes, J. Délaux, and Criterion. In the incurved a collector must have, amongst others, Empress of India, Lord Leicester, Empress Eugénie, Barbara, Golden Empress of India, and Hero of Stoke Newington. Among the reflexed, Chevalier Domage, Dr. Sharpe, King of the Crimson, Cloth of Gold, Cullingford, and Golden Christine are at top. In large Anemones, Empress, Gluck, Mrs. Pethers, and Fleur de Marie; and of Japanese Anemones perhaps Fabian de Mediana, Mdle. Cahrol, Sœur Dorothee Souille, Madame Berthe Pigny, and Madame Clos are the best. There are also many novelties in the various classes, but these have yet to be proved before they can be recommended to the amateur cultivator. It is of the highest importance, especially where the number of plants grown is limited, to make a judicious selection of suitable varieties. One continually sees at shows varieties exhibited which ought to have been excluded years ago. To retain such spoils the board, and weakens the exhibitor's showing power."

"Can general interest in the flower be so promoted as to make it the winter flower *par excellence*, as the Rose is that of the summer?"

"I think that we may almost say that the Chrysanthemum is already the winter flower. A recent inquiry, instituted, I believe, by the National Chrysanthemum Society, has shown that in this country alone there are 100,000 growers of the Chrysanthemum. This tells its own tale as to the popularity of the flower. Of course, to keep to the front rank at the larger shows is another question. In such competitions, as in every other where the front rank has to be reached, the individuality of the cultivator comes in. The thought and industry needed on the part of the gardener who is to win in first-class contests must, I need scarcely say, be beyond the common. In such a season as the past special devices had to be considered, and means found to neutralise the effects of the almost constant rain. I was asked by a gentleman at the Aquarium what was my gardener's secret in producing the fine blooms staged by him. My reply was, 'Eleven, or I should say, twelve months' constant and intelligent care.' This is the real secret of success, rather than any special and complicated 'composts' or manures. Furthermore, one must not stand still; constant experiment to feel your way onward must not be neglected. One important element in the matter is also an accurate knowledge of the peculiarities of the several varieties with a

view not only to their general culture but to the accurate 'timing of the buds' so that they shall present themselves for 'taking' exactly at that period which (having regard to the date of the show) is most calculated to produce the finest blooms. Here we have one of the inner secrets of the cultivator—a secret which he generally manages to keep to himself. There are three rocks upon which the amateur generally comes to grief. These are over-potting, over-watering, and over-feeding the plants. As to the general question of the advisability of permitting one's gardener to show, my view is, encourage it. It is often said that if showing is allowed other things are neglected. I have not found it so. I think that no honestly minded gardener will neglect his employer's interests in such a case. Should it, however, in particular instances be found to be otherwise, then by all means at once have an understanding on the point. I think that showing should be encouraged for many reasons. Intelligent and active-minded men in every class need some outlet for their surplus mental activity and legitimate ambition. What better channel into which to divert them than their ordinary calling and occupation? I have seen something of the gardeners who stand as the leading competitors and prizewinners at these shows, and I can testify to their superior bearing and intelligence. Such men cannot fail to raise the moral standard of their whole class. Again, on the general question of encouraging horticultural tastes amongst the poorer classes, our cottage shows, and the kindly emulation which they stimulate, are, I think, not without their value at a time when so many things exist to sunder instead of draw closer the different classes of the community. Besides, we must all have, in reason, our pleasures and amusements. Lord Bacon said that 'of all earthly pleasures gardening was the purest.' I think that Lord Bacon was not far out in his statement."

FISH POTASH MANURE.

LAST year I had occasion to write favourably of this manure, and on further trial of it I can express myself as more pleased with it than before. During the past season I used it for Chrysanthemums, Potatoes, Onions, Tomatoes, Cucumbers, Melons, &c., so that I gave it a fair trial, using 15 cwt. of it. Sown in the ridges with the seed Potatoes it produced starchy, but not rampant growth, with the foliage of a dark healthy colour. On lifting the crop was all that could be desired, and for my soil remarkably clean. For Tomatoes it was dug in with some quarter-inch bones, and I had a very fine crop of fruit, growing them in a similar manner to that at Chiswick, with the exception that my stakes were all slanted, the house being three-quarter span, and the glass going down to 1 foot from the soil. The first two rows, in fact, were trained along the wires, there not being height enough for stakes. The plants were grown on the single-stem system, and I found the result from the house in which the potash was used far superior to that in which horse manure was dug in. In the latter the growth was rampant, the flowers would not set, and when they began to carry fruit the bunches were small, but the fruit weighed 9 and 10 ozs. each. With the potash the fruit was borne from about 9 inches above the soil, the growth was short-jointed, carrying a regular crop of fair-sized bunches of fruit, averaging 5 ozs. each. This manure was also very satisfactory used in Cucumber house and Melon frames, for my Cucumbers bore well from March to the beginning of November, and my Melon plants carried two crops, although I am sorry to say I failed to ripen many of the later ones. However, I cut forty-two from a three-light frame as a first crop, which I considered very satisfactory, the fruit averaging 2½ to 3 lb. each. I may add that I was successful when exhibiting a dish of Tomatoes against eight others last week, being awarded the premier place at our local Chrysanthemum Show, and my fruit have commanded 2d. per lb. more than that of other growers in my neighbourhood throughout the summer.—H. S. EASTY, *Cornard, Sudbury, Suffolk.*

POINSETTIA PULCHERRIMA.

FEW winter flowering plants are more effective than the Poinsettia when well grown; its bright crimson bracts render it attractive in the stove or warm conservatory. It is also useful associated with Palms, Ferns, Richardias, and Primulas for room decoration. A few remarks on its cultivation may be of interest to some of our readers. After the plants have flowered they should not, as is frequently the case, be laid under the stages and allowed to take care of themselves until the time for propagation comes round, but be kept near the glass and attended to in watering until the leaves fall, after which less water will be required. They may then be transferred to a house or pit where the temperature does not fall below 50°. Towards the end of April treat the plants more generously by syringing them and closing the pit early in the afternoon, taking care not to overwater them. By these means strong healthy cuttings will be secured, not the least important point in their cultivation. When the shoots are about 2 inches long they should be taken off with a heel and inserted singly into small pots in a light compost of loam, leaf soil, and sand, well watered and plunged in a bottom heat of about 50°. Where a large stock is required successional cuttings may be taken.

As soon as the cuttings are rooted remove them from the propagating pit into a temperature a few degrees lower, keeping them near the glass. Repot them as they require it in a mixture of

loam two parts, leaf soil and Mushroom bed manure one part each, with sufficient sand to keep the compost open. Equally good results may be obtained in 5 or 6-inch pots as in those of larger dimensions. The plants should stand on a hard surface to prevent the ingress of worms. Plants raised yearly give better results than old plants cut back. When they have been gradually inured to the air the lights may be drawn off altogether, as they are greatly benefited by the dews; but it will not be safe to leave them off after the middle of September. Keep the plants well syringed, and give an occasional surface dressing of artificial manure. Sturdy plants clothed with thick leathery foliage to the edge of the pot should be the aim of the cultivator. Without this condition large bracts cannot reasonably be expected.—J. CLEARE.

EVENTS OF THE WEEK.—To-day (Thursday) the annual meeting of the National Rose Society will be held at 3 P.M. in the "Hotel Windsor," Victoria Street, Westminster, Dr. Robert Hogg in the chair. The Society's annual dinner will be held at 6 P.M. the same evening in the hotel named. The Royal Horticultural Society's Fruit and Floral Committees will meet in the Drill Hall, James Street, Westminster, at 11 A.M. on Tuesday, December 11th, and the National Chrysanthemum Society's annual dinner will be held in "Anderton's Hotel," Fleet Street, at 6 P.M., on Thursday, December 13th. The usual sales of bulbs and plants will be held by Messrs. Protheroe & Morris, Stevens, and Smail & Co.

— **ROYAL HORTICULTURAL SOCIETY.**—The following notification has been sent to us:—It is anticipated that there will be six vacancies at least on the Council of the above Society to be filled by the Fellows at the annual meeting in February next. The following gentlemen have signified their wish to be relieved of the work, which during the present year has been very heavy—viz., Mr. Thiselton Dyer, Prof. Michael Foster, Dr. Hogg, Sir Edmund Loder, Mr. Harry Veitch, and Mr. G. F. Wilson.

— **THERE** are two interesting facts in relation to RHODODENDRON FORTUNEI, of which you published a very pretty figure in last week's issue. They are—First, This is the only garden Rhododendron from China, whence it was sent by Fortune in 1859. Second, That the flowers have six, often seven segments in the corolla, and fourteen stamens, whereas the usual number are five of the former and ten of the latter. There are some fine examples in the Rhododendron dell at Kew, which flower freely every year.—W.

— **THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.**—A legacy of £50 has been bequeathed to this Institution by the late Mrs. Cameron, who was the widow of the late Mr. George Cameron, who for many years was the respected head gardener to the Duke of Richmond at Goodwood Park, Sussex. He was a life member of the Institution, and died in 1870.

— **THE KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY** will hold their thirteenth annual Exhibition on Nov. 12th and 13th, 1889. Mr. G. Woodgate, Warren House Gardens, Kingston-on-Thames, is the Hon. Secretary.

— **WE** are glad to learn that the first prize, consisting of a gold medal, has been awarded to MESSRS. H. P. BULMER & Co. OF HEREFORD for their noted Credenhill cider in bottle, shown by them at the great Exhibition now being held in the Palais de l'Industrie at Paris.

— **THE Hereford Times** says:—"Le Cidre of the 25th November gives an account of the INTERNATIONAL EXHIBITION OF CIDER AND FRUIT which has just been held at the Palais de l'Industrie in Paris. In the class for cider, open to Switzerland, England, the United States, Canada, and Germany, the first prize medal was awarded to Messrs. Bulmer & Co. of Credenhill; the second to Mr. Ham, of Exeter; third, Mr. Bosley, Lyde; fourth, Mr. Watkins, Hereford; and fifth, Mr. M. Jones, Hereford. For perry, Messrs. Bulmer & Co., of Credenhill, took first prize; second, Mr. Watkins, Hereford; and third, Mr. Jones, Ledbury. For cider and perry fruit, Mr. John Watkins, Pomona Gardens, Hereford, took the second prize of a silver medal; and Mr. Jones, Ledbury, third,

— **WE** have received the preliminary programme of an INTERNATIONAL HORTICULTURAL EXHIBITION, which is to be held at Berlin from the 25th of April till the 5th May, 1890. Judging from the number of classes, it is intended to be a very grand affair. We should like to see a thorough good exhibition of German horticulture, and there is no better place for it than Berlin.

— **GARDENING APPOINTMENTS.**—Mr. T. Grant has resigned his situation as gardener to Major Murray, Ossemsley Manor, Christchurch, to take charge of the gardens and grounds at Silwood Park, Sunninghill, Ascot, for T. Cordes, Esq., who has lately purchased the above estate. Mr. J. Smart, late fruit foreman to His Grace the Duke of Portland, Welbeck Abbey, Notts, has been appointed head gardener to Sir Ralph Payne Gallwey, Bart., Thirkleby Park, Thirsk, Yorks.

— **GRAPES AT THE LIVERPOOL SHOW.**—A correspondent, who was not an exhibitor, desires to state that the Judges at the above Show awarded an extra prize for a basket of splendid Grapes; but the Committee, as they had power to do, overruled it, granting a certificate instead. Our correspondent thinks this might have been granted in addition to confirming the Judges' award, as the latter would have assisted in defraying travelling charges to the Show.

— **THE** very pretty climber, ECCREMOCARPUS SCABER, is of vigorous growth, and if planted against a south wall it will endure the winter provided the roots are protected with some long litter or leaves. It flowers from July to November. The orange scarlet corollas are very attractive and freely produced on the young growths. Seeds are ripened readily, which should be sown in pans on a hotbed. When the seedlings are large enough they may be potted singly into thumb pots placed in heat a few days until established, when they should be moved into the greenhouse and shifted into larger pots as they require it until planting-out time in May. Any light garden soil will suit them admirably.—J. L., Bishops Waltham.

— **IT** was noted a short time since that Mr. J. F. DUTHIE, Director of the Botanical Department, Northern India, had accompanied the recent military expedition to the Black Mountain country. The Black Mountain forms the northern boundary of the district of Hazara, which forms a long narrow valley, bounded on the west by Cashmir. Extending far into the heart of the outer Himalayan range, it is shut in on either side by mountains, rising to 17,000 feet. The flora is almost wholly unknown. But the time of the year was unfavourable for botanical collecting, and Mr. Duthie writes to Kew—"I did not manage to find much of botanical interest on the Black Mountain; excepting the fine bits of forest, composed of Abies Webbiana and Pinus excelsa on the crests of the mountain, the country is barren in the extreme."

— **THE REAR GUARD OF SUMMER.**—Mr. G. E. Aldridge, F.G.S., writes from Winscombe, Somerset:—"It may interest many of your readers to know that during the last week or two the following flowers have been seen in cottage gardens on or around the Western Mendips—Arabis (white), Arbutus, Calceolaria (small yellow), Canary Creeper, Chrysanthemums, Dahlia, Escallonia, Eschscholtzia, Fuchsias, Gladiolus, Hollyhock, Honeysuckle, Hydrangea (pink), Jessamine (yellow winter), Laurustinus, Lobelia (blue), Magnolia (large buds just expanding), Marigold (common and African), Mignonette, Myrtle (buds large and healthy, here and there a flower), Pansy, Passionflowers, Peas (Sweet), Petunia (white and variegated), Phlox (tall lilac and dwarf red), Pink, Pyrus japonica, Roses (three or four sorts), Snapdragon, Stock, Tritoma, Valerian, Verbena (red), Veronica, Violet, Wallflower. This profusion of flowers is all the more remarkable, following, as it does, on a very cold October, a cold and rainy summer, and a generally cold period of fourteen months."

— **AT** the ordinary weekly meeting of the members of the WAKEFIELD PAXTON SOCIETY, held at the "Saw Hotel," Councillor Milnes, the President, was in the chair, and Mr. Brown, gardener at Hatfield Hall, occupied the vice-chair. The subject for discussion was "The Chrysanthemum," and it was introduced by Mr. T. Garnett one of the Honorary Secretaries. He read a capital paper on the subject, and gave some useful and valuable advice to growers of the Chrysanthemum, of which he exhibited a dozen remarkably fine specimens. An interesting discussion followed, in the course of which it was mentioned that vast quantities of Chrysanthemums have been lost this season owing to the wet and almost sunless summer and the keen frost, which played sad havoc with the plants during the first week in

October.' At the close of the discussion, Mr. T. Senior, solicitor, an ex-President of the Society, proposed a vote of thanks to Mr. Garnett, and it was seconded by Mr. W. Glover, supported by Mr. George Gill, and very heartily carried and suitably acknowledged.

— **WAKEFIELD PANTON SOCIETY.**—The following is a programme of meetings for the fourth quarter, session 1888-9. Meetings are held at the Society's rooms, "Saw Hotel," Westgate, each Saturday evening commencing at eight o'clock prompt. 1888—December 8th, "A few Hints on Watering," Mr. L. Twigge. December 15th, "Our Fishermen; How and Where they Live," Mr. C. J. Willis. December 22nd, "Soils and Manures Suitable for the Vine," Mr. J. P. Carter, Cowick. December 29th, Musical Evening; Mr. T. Carbert and party (Sale of periodicals). 1889—January 5th, "Asparagus; Its Culture," Mr. James Keighley, Bradford. January 12th, "The Eucharis amazonica," Mr. W. Daniels, Mirfield. January 19th, "The Primula," Mr. E. Fenner. January 26th, "The Azalea," Mr. W. Frankland, Leeds (Sale of periodicals). February 2nd, "Origin and Function of Fruit," Mr. T. Garnett. February 9th, "Hardy Shrubs for Forcing," Mr. J. G. Brown. February 16th, "The Vascular System of Plants," Mr. G. W. Fallas. February 23rd, "The Hyacinth for Decorative Purposes," Mr. G. Wassell (Sale of periodicals). March 2nd, Annual Meeting. Messrs. G. W. Fallas and T. Garnett are the Hon. Secs.

— **THE MILD NOVEMBER.**—When severe frosts occur early in October a term of mild weather often follows—a second autumn, as it is sometimes described. Referring to the mild weather that has prevailed in the south of England of late, a daily paper says:—"Only four times during the month of November has the minimum temperature for a day fallen below the mean, and only once has it gone so low as freezing point. If the average of all the daily minima is taken it gives a result more than $5\frac{1}{2}^{\circ}$ above what is usual. Similarly the daily maximum has only six times failed to reach the mean, and has only once fallen short of 40° . On one occasion it was more than 10° above the mean, and has been on the whole nearly $2\frac{1}{2}^{\circ}$ higher than usual. With the exception of half the second week in the month, when an anticyclone over the North Sea brought a few cold days, we have been under the influence of cyclonic disturbances. The storms and wrecks which have taken place on our coasts have resulted from the same movements of the atmosphere which have brought us the warmth of the Bay of Biscay and of the hills of Spain."

— "M. C." writes—"In Messrs. Parker & Son's nursery, St. Michaels Hill, Bristol, may be seen at the present time a very fine house of **WHITE BOUVARDIAS**. The majority of the plants are B. candidissima. Although other sorts are fully represented, none can approach the free-flowering character of this variety. The plants, I was informed, were raised from cuttings struck and potted late in May, and although rather backward in making a start, the growth that ensued consequent on judicious application of sulphate of ammonia and a subsequent shift into 6-inch pots was all that could be desired. As a variety of sterling worth it appears to be pre-eminent both on account of its habit of rooting quickly from cuttings, its vigorous growth, and also its superiority for producing a wealth of pure white and delicately scented flowers at a time of the year when such are greatly appreciated. The habit also of flowering freely from side shoots is, moreover, very marked in this variety, enabling the plant to produce a long succession of bloom, a matter of great importance where the plants are grown as they are in Messrs. Parker's establishment to supply cut flowers for the daily manufacture of bouquets, wreaths, and other floral decorations.

— **THE recent CHRYSANTHEMUM SHOW AT ASCOT** was a great success both as regards exhibits and the attendance of visitors. Groups are always remarkably well shown here, and this year were better than ever. Mr. Lane, gardener to Miss J. Smith, King's Ride, Ascot, has several years held the leading position, and on this occasion his group was probably the best he has ever put together. The plants composing it were dwarf, well arranged, and carrying extremely fine flowers. This exhibitor also succeeded in winning the challenge cup offered with the first prize for thirty-six cut blooms (half incurved, remainder Japanese) which has to be won three times before finally won. This has now been won by three different competitors. Last year's winner, Mr. Pape, The Highams, Bagshot, having recently changed situations, was placed at a disadvantage; he was, however, a very good second. Mr. Popple was awarded the special prize for the best Japanese bloom in the Show; and Mr. Hughes for the best incurved bloom—Golden Dragon and Empress of India respectively. Other successful exhibitors were Messrs. Cole, Sinclair, Thorne, and Woodhouse.

— **CARTER'S PROVIDENT SICK FUND.**—The third annual meeting of members was recently held in the warehouse of Messrs. James Carter and Co., High Holborn. The chair was occupied by Mr. C. H. Sharman, the general manager, who in a few well chosen remarks pointed out the usefulness of the Society. The number of subscribers during the year had been 289, making a total of 449 during the short existence of the Society. Fortunately there was no case of the death of any member to be recorded, but fifty-three members had become chargeable to the funds by reason of sickness during the year, and the payments on that head were one and a half times in excess of the previous year. Nevertheless it was found possible to set aside a further sum of £25 to the reserve fund, to make a donation of £10 to the Hospital Saturday Fund, and to distribute a bonus at Christmas, which should represent rather more than half the year's subscription of every participating member; after providing for these a comfortable working balance would still be held in hand. All the officers are honorary. The confidence of the members in the executive officers was shown by the unanimity with which they were re-elected, and a very pleasant meeting terminated with the usual vote of thanks to the Chairman.

— I HAVE read with much interest from time to time the controversy on **GRAPES SCALDING** which has been published in the Journal. One of the vineries in my charge, about 90 feet long, contains a collection of Grapes—viz., Black Hamburgh, Lady Downe's, Madresfield Court, Alicante, Gros Maroc, Muscat of Alexandria, and several other varieties. The Vines are about twenty years old and trained on the front trellis, and all receive the same treatment. The house is ventilated by two levers, and air is admitted equally the full length of the house, and in the evenings reduced accordingly. Yet amongst all the Vines we had no scalded berries except on Lady Downe's, and which were so bad that most of the bunches had to be cut off. I might also state that of the last mentioned two Vines were growing in the middle of the house, so that the morning or evening sun could not strike the bunches; they also had ample foliage and are in excellent health. If Mr. Bardney believes that other Grapes are as easily scalded as Lady Downe's, I should be glad if he would explain through your paper how it was Lady Downe's scalded and all the others escaped.—J. B.

— **MR. J. MALLENDER** sends the following summary of **METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR NOVEMBER**:—Mean temperature of month, 45.6° . Maximum on the 16th, 60.5° ; minimum on the 28th, 29.5° . Maximum in the sun on the 20th, 97.4° ; minimum on the grass on the 28th, 20.2° . Mean temperature of the air at 9 A.M., 45.2° . Mean temperature of the soil 1 foot deep, 45.7° . Nights below 32° , in shade one, on grass nine. Total duration of sunshine in month, thirty-one hours, or 12 per cent. of possible duration. We had fifteen sunless days. Total rainfall, 3.87 inches. Rain fell on twenty-three days. Average velocity of wind, 15.3 miles per hour. Velocity exceeded 400 miles on twelve days, fell short of 100 miles on one day. Approximate averages for November:—Mean temperature, 41.7° ; sunshine, fifty-three hours; rainfall, 2.04 inches. The warmest, wettest, dullest, and most windy November yet recorded here, except that November, 1881, was warmer. The nights have been especially warm. Primroses and Daisies are flowering freely.

— **MR. A. CHAPPLE**, Cattistock Lodge Garden, Dorchester, writes:—"The **RAINFALL FOR NOVEMBER** taken at this place was 10.28 inches. As I only commenced the beginning of the year recording it, would you state in your Journal the average fall for November; and if this is the biggest fall of rain you have heard of for last month?" [This is the "biggest" that has been sent to us, and if accurate, is, we suspect, unusual for the district.]

— **THE Kew Museum** has lately received a choice collection of interesting **BOTANICAL OBJECTS FROM COREA**, collected and brought home by Mr. T. Watters, who was Acting Consul in that country from January 1887 to June last. The specimens in question, which consist of hand-screens, fans, &c., made of paper from the Paper Mulberry (*Broussonetia Papyrifera*, Vent.), together with samples of the paper itself, sun-blinds made of split bamboo, &c., illustrate in a remarkable degree the extreme neatness and accuracy of the Koreans in their handicrafts. The following are some of the specimens received and now exhibited in the Kew Museum:—A series of different qualities of paper, all made from the bark of the Paper Mulberry. These comprise plain white or cream-coloured papers of various degrees of finish, used for drawing, writing, packing, &c.; also coloured papers such as are used by the people for writing birthday missives upon. It would seem that the Koreans, like the Japanese, use paper very extensively for a

great variety of purposes. Thus, for fans, the handles of which are delicately ornamented, as well as for hand-screens, tobacco-pouches, coverings for hats in wet weather, paper is equally applicable: for the latter purpose, however, it is steeped in oil, which makes it thoroughly waterproof. The hand-screens are made by first forming a foundation of thin strips of split bamboo radiating from the handle, which is afterwards covered so completely on both sides with a thin paper film and varnished that a strong and durable article is the result.—(*Nature*).

ODONTOGLOSSUM HARRYANUM.

LIKE most of the cultivated *Odontoglossums* this species is evidently extremely variable, and it is somewhat strange that by far the best varieties have come into notice some time after the type was made known. It was introduced several years since by

Fig. 56.—*ODONTOGLOSSUM HARRYANUM*.

Messrs. Horsman & Co., Colchester, but subsequently passed into the hands of Messrs. J. Veitch & Sons, Chelsea. It was named in honour of Mr. Harry J. Veitch by Professor Reichenbach, who said, "It is a fresh type, a grand and unexpected surprise, comparable with *O. luteo-purpureum* and *O. tripudians*." The original form as figured in Veitch's "Manual of Orchidaceous Plants" is much inferior to that represented in our illustration (fig. 56), which was prepared from a flower shown at one of the meetings of the Royal Horticultural Society in the past season. In most large collections of Orchids *O. Harryanum* is now included, and is rapidly becoming a favourite, though we have not yet seen established plants with many flowered scapes 2 to 3 feet long, as promised by some who have described the plant. Messrs. J. Veitch thus describe the originally introduced form:—"Pseudo-bulbs oval-oblong, compressed, furrowed and ribbed when old, 2½ to 3 inches long, diphyllous. Leaves leathery, oblong, obtuse, 7 to 10 inches long. Scapes but imperfectly developed from the imported plants. Flowers 3 to 3½ inches across, vertically; sepals elliptic-oblong, wavy, deep chestnut-brown marked and tipped with golden yellow; petals oblong, acute, reflexed at the tips, the basal half white, traversed longitudinally by broad, close-set mauve-purple lines; central area chestnut-brown, apical part yellow; lip oval-oblong, three-lobed, the side lobes rotund, turned upwards, white, heavily striped with mauve-purple, the anterior lobe sub-

cordate, white, changing to pale yellow; crest deeply fimbriate in front, golden yellow. Column terete with two minute apical toothed wings, white at the base, changing to yellow upwards." The variety represented in our woodcut is distinguished by the great breadth of the sepals and petals, especially of the former, the colouring being also deeper and richer.

ORCHIDS IN FLOWER.

IN Mr. A. H. Smee's garden, The Grange, Hackbridge, the following Orchids are now in flower in the different houses, and the list will give an idea that they are by no means dull. *Angræcum sesquipedale*, *Barkeria elegans*, *B. Lindleyana*, *Cattleya Dormaniana*, *Cœlogyne assamica*, *C. speciosa*, *Cymbidium giganteum*, *Cypripedium Harrisianum*, *C. insigne*, *C. insigne Chantini*, *C. insigne Maulei*, *C. Schlimii album*, *C. Spicerianum*, *C. venustum*, *C. villosum*, *Dendrobium bigibbum*, *D. heterocarpum*, *D. Wardianum*, *Dendrochilum uncatum*, *Disa graminifolia*, *Epidendrum xanthinum*, *Lælia autumnalis*, *L. a. Protheroianum*, *Lycaste plana Cumminsi*, *Lycaste Skinneri*, *L. Smeeana*, *Masdevallia attenuata*, *M. amabilis*, *M. Chimæra*, *M. Chimæra Gorgona*, *M. Davisi*, *M. Harryana*, *M. Houtteana*, *M. macrura*, *M. tovarensis*, *M. triangularis*, *Maxillaria nigrescens*, *M. palmifolia*, *Odontoglossum Alexandræ*, *O. Cervantesi*, *O. constrictum*, *O. Insleayi splendens*, *O. luteo-purpureum*, *O. maculatum*, *O. nebulosum candidulum*, *O. Pescatorei*, *O. pulchellum majus*, *O. Rossi majus*, *Oncidium cheirophorum*, *O. crispum*, *O. flexuosum*, *O. Forbesi*, *O. ornithorhynchum*, *O. Phalænopsis*, *O. varicosum*, and *Phalænopsis leucorrhoda*.

One large plant of *Oncidium crispum* is very remarkable. The pseudo-bulbs were made out of doors between July and September, and when taken in the flower spikes were about 14 inches in length, the two spikes together produced 100 blooms; unfortunately the point of one was broken off or there would have been twenty more flowers at least. The *Disas* are thriving.

The following Orchids are flowering now in Messrs. John Laing & Sons' Nurseries, Forest Hill:—*Calanthe vestita*, *C. vestita rubro-oculata* and *rosea*, *C. Veitchi* and the variety *superba*. *Cattleya gigas*, *Cœlogyne Turneri*, *Cypripedium Harrisianum*, *C. insigne* and the variety *Maulei*, *C. Spicerianum*, *Dendrobium formosum giganteum*, *Galeandra Dives*, *Lycaste Skinneri alba*, *Masdevallia Harryana*, *M. Lindeni*, *M. tovarensis*, *Odontoglossum Alexandræ*, *O. grande*, *O. Pescatorei*, *Oncidium Marshallianum*, *O. tigrinum*, *O. varicosum Rogersi*, *Phalænopsis amabilis*, *P. grandiflora*, *Pilumna nobilis*, *Sophrontis grandiflora*, and *Zygopetalum intermedium*.

ONCIDIUM AUROSUM.

I HAVE three plants of *Oncidium aurosium*, which I fail to flower to my satisfaction. I have heard of it being grown with 200 flowers on a spike. I have had it now for three years, and have never been able to get more than twenty to thirty flowers on a spike at the most. Perhaps some of your correspondents will be able to enlighten me on the subject as to temperature and the soil it requires. Our plants are grown in a temperature of 65° by day, falling to 58° by night, or thereabouts. They are in a mixture of peat, sphagnum moss, charcoal, and sand. I may also mention that the house is an early vinery, and the plants remain in it all the year round. Would the shade of the Vines have anything to do with it? They make strong growth with stout leathery leaves. I manage to flower amongst others *Oncidium ornithorhynchum*, *Cymbidium eburneum*, *Cattleya crispa*, and *C. Mossiæ superba* in the same house.—B. P. D., Wakefield.

A VISIT TO BOLTON HALL.

Now that the season for *Chrysanthemum* shows is drawing to an end, I have sent you a short account of what I saw of fruit-growing in Wensleydale, in the North Riding of Yorkshire. Having a little time to spare I paid a visit to the above named establishment, the Yorkshire seat of Lord Bolton, when I was met by the courteous gardener, Mr. Hall, who kindly took me round the grounds. He evidently is an enthusiast in fruit-growing, and although such a bad season I was agreeably surprised to see a very fair crop of fruit, both Pears and Apples. Some of the Pears were of a good size and well coloured for the north of England—i.e., *Pitmaston Duchess*, *Souvenir du Congrès* (good colour), *Doyenné Boussoch*, *Jersey Gratioli*, *Beurré Diel* (very good), *Beurré Clairgeau* (good colour), *Hacon's Incomparable*, and many others. Mr. Hall likes to try experiments, for the trees are grown on the wall and are very old, the stem being carried along close to the ground and a number of verticals taken up from them. I enclose the measure of some and number grown on each. No. 1—length 26 feet, height 14 feet, thirty-six vertical rods, ten varieties as follows: *Fondante d'Automne*, *Doyenné d'Été*, *Marie Louise*, *Napoléon*, *Marie Louise d'Uccle*, *Doyenné du Comice*, *Prince of Wales*, *Doyenné Boussoch*, *Citron des Carmes*, *Dr. Trouseau*. No. 2 Pear, 14 feet high, 17 feet long, eight varieties—*Beurré Clairgeau*, *Passe Crasanne*, *Beurré de Rance*, *Beurré Diel*, *Comte de Lamy*, *Winter Nelis*, *Marie Benoist* and *Thompson's*.

No. 3 Pear, 14 feet high, 23 feet long, thirty-four vertical rods, ten varieties. No. 4—Marie Louise, 14 feet high, 23 feet long, thirty-one vertical rods. No. 5—12 feet high, 39 feet long, or 39 yards, and forty-seven vertical rods. I was convinced from what I saw of the trees and fruit that Pears if well looked after, and suitable sorts planted, would do well in the north. I must not forget to mention the well cropped kitchen garden with abundant supplies for winter use. A capital collection of Orchids is being formed. The favourite tree at Bo ton Hall seems to be the Yew, for it is seen in all parts of the grounds. There are some fine Larch trees on the estate. From the shawl at Leyburn a magnificent view of the county is obtained. It is regarded as one of the finest natural rock terraces in England.—A. J. BROWN.

GARDENERS' ORPHAN FUND.

THOUGH the night was so inclement there was a large attendance at the Committee meeting held on Friday night last. The subject of collecting boxes was prominent. Some time ago a gross of these was purchased for £8 15s., and already the returns from them exceed £15, while a large number have not been opened. To meet further applications from friends of the Charity more of these boxes were ordered for distribution. It is found the excellent custom is growing of passing these boxes round at flower shows, and that much more is dropped into them in this way than by leaving them stationary, no matter how prominent the positions. There can be little doubt that when the general public, who are interested in flowers and gardening generally, become acquainted with this fund and the great need for its existence, that a substantial amount in the aggregate will be received in the form of a large number of small contributions by visitors to horticultural shows, and it is hoped there will not be wanting friends to act as helpers of the Charity on those occasions. At the meeting under notice upwards of £12 was paid in, including £2 by Mr. W. Bates, collected at the Twickenham Show; £3 6s by Mr. G. Bishop (Teddington Show); £1 10s. 6d. from Mr. Scott (Bradford Show); £1 ls. from Mr. Wooderson (Bexley Show); and £1 ls. 3d. by Mr. G. Cummins, from visitors to The Grange Gardens, Hackbridge, and the Croydon Show. Grants were mentioned as probable from the Committees of the York Show and the Yorkshire Union of Horticultural Associations. A letter was read from Mr. Drummond of Stirling to the effect that he could get little or no support for the Fund in Scotland. This is the experience of the Committee, but they are not in possession of facts accounting for the circumstance. Scotland, however, supplies two excellent officials in Mr. A. F. Barron and Mr. J. Walker. An offer, the first of the kind received, was made by a gentleman to take charge of one or two children, as his home was childless. The thanks of the Committee were accorded to all who had kindly assisted the Charity and made it and its objects known in the districts in which they reside. It is believed there are noblemen, ladies and gentlemen who would not be unwilling to open their gardens to the public for a day at a convenient time in the summer, subject to a small charge for admission, in support of the Charity, if its nature were brought before them. This has been done at Heckfield and a few other places with gratifying results.

FLORAL CONCERT.—I have the pleasure to acknowledge the receipt of cheque, value £31, from Mr. O. Thomas, Chatsworth, as the result of the floral concert held at Chesterfield on November 14th, in aid of this Fund. Very great credit is due to Mr. Thomas and his fellow gardeners, members of the Committee—viz., Messrs. W. H. Horabin, W. R. Bloxham, H. Smale, W. E. Jenkinson, J. Fletcher, J. J. Nelson, G. Parkes, S. Polkinghorne, W. Leighton, J. Turguy, and J. Hutton, who have worked so energetically with Mr. Thomas to achieve such a splendid result.—A. F. BARRON, *Hon. Secretary*.

A GOOD EXAMPLE.—At the Birmingham Chrysanthemum Show, Mr. Hughes, the Secretary, and local Secretary of the Gardeners' Orphan Fund, engaged a bright little girl to walk about the Exhibition with an Orphan Fund box fastened to her breast for the reception of gifts from a penny upwards—but a penny was asked for—and with contributions from exhibitors a sum of £3 or so was collected for the Orphan Fund. If this could be done at all flower shows, even with much smaller amounts, what a goodly sum would result. Flower shows as a rule should do something for the horticultural benefit societies, and a small subscription or donation would not be missed. In the Black Country there is a small place—Darlaston—which has its three year-old Floral Society, and the Committee have just voted the sum of 10 guineas to the Free Library fund there, from the profits of their Exhibitions.—W. D.

FRUIT CULTURE ON SMALL FARMS OR ALLOTMENTS.

MR. S. RAWSON labours in the right path, and his efforts to arouse greater attention to the important question of fruit culture should be well supported, and the cause not only of fruit culture but flower and vegetable culture also spread throughout the land. Is it not a mistake to send out of the country £25,000,000 for the common necessities of life, and £8,000,000 annually for fruit? Surely it is not impossible to reserve a portion of the above vast amount without impairing the interests of other crafts. In these days, when every help is needed to guide and better the condition of the masses, if we cannot hold out the hope of all being able to sit under their own Vine and Fig tree it is not

unreasonable to give the masses an opportunity of being able to appreciate home produce in preference to foreign productions.

It would be well if spade culture was more adopted, for without doubt it is the best implement for turning up the soil, and the greatest returns follow. Therefore it is most desirable to develop the resources of the soil chiefly by spade culture. The landlords might be invited to help the industrious by providing the raw material to work on, and the workers want good rules to guide them in their operations. Depend upon it there lies in the better cultivation of the land remedies for many of the evils which wound the feelings of civilisation.—X.

DICENTRA CANADENSIS.

UNDER the name of Dicentra are included several elegant hardy plants which have been variously named Dielytras or Dielytras and Corydalises. Some of these are familiar plants in North America, bearing special popular names like Dutchman's Breeches (Dicentra cucullaria) and Squirrel Corn (D. canadensis), the last named being

Fig. 57.—DICENTRA CANADENSIS.

the subject of our illustration (fig. 57), and one of the most graceful of the family. In Canada and some of the Northern United States this Dicentra is frequently found in rocky woods, producing its white and purple tinted fragrant flowers freely during May and June. The leaves are finely cut and slightly glaucous, forming a dense tuft from which partially drooping racemes arise bearing the neat pendulous flowers. The plant is a perennial with numerous small yellow pea-like tubers; it is hardy, readily increased, and succeeds well on a rockery or in an ordinary border.

PLUMS AND THEIR PRESERVATION.

AT a recent meeting of fruit-growers in Gloucester, Mr. M. W. Colchester-Wemyss read a paper on French Plums, and the methods of preservation adopted on the Continent, from which we extract the following:—

In the autumn of last year the idea occurred to Sir W. Wedderburn that it might be possible to make so-called French Plums in Gloucester-

shire. He, some few others, and myself, had conversations on this particular point, and also on the general subject of the best means to adopt in order that our fruit-growing districts in this county might extend the scope of their operations and might take measures to avoid the great loss that occurs when the market prices for fruit are very low. Such was the case the year before last, when quantities of fruit literally rotted on the ground because it did not pay to incur the expense of gathering and sending it to market. The idea eventually arrived at was that a factory might perhaps be established in the heart of one of the districts for the conversion of Plums into French Plums and Prunes, and for various other processes of fruit preservation. Four or five subscribed a small fund to be expended in obtaining information, and, as the result of our deliberations, we determined to endeavour to procure the services of a Frenchman acquainted with the French Plum process, who would come to Westbury and try experiments with our local produce; and it devolved upon myself to carry out this idea. I accordingly inserted advertisements in French papers and corresponded with several Frenchmen, but with no result beyond ascertaining that great ignorance existed on the subject. At last one day I was in the offices of a friend of mine in London, when two Frenchmen came in, with one of whom I was slightly acquainted. I at once asked him if he could tell me anything about French Plums, and he said, "Oh! no; but my friend here, M. Calvet, can." M. Calvet, who is one of the very largest of the Bordeaux shippers, then told me that he knew the Plum district well, and that he was intimately acquainted with a gentleman, by name M. Gajac, who was very largely interested in the Plum trade, and that he would at once write to him on my behalf. He did so, and in the course of a few days I received a most courteous letter from M. Gajac, offering to give me all the information I might desire. A lengthy correspondence ensued between us, and M. Gajac assured me it would be almost impossible to find a competent Frenchman able and also willing to come to Westbury, and even if such a man were found it would entail a very considerable outlay, and he gave me a courteous invitation to come and see the process on the spot myself. There is an old saying that when the mountain would not come to Mahomet, Mahomet had to go to the mountain, and so it seemed that I could not do better than adopt M. Gajac's very pleasant advice. So about the middle of August, as soon as I heard that the Plum season had commenced, I started off on my 500 miles' journey to the south of France.

About sixty miles from Bordeaux there falls into the Garonne a fine river, which, taking its rise among the mountains of Cevennes, follows a course of some 150 miles until its junction with the Garonne. The river is called the Lot, and the two rivers together confer the names on the department known as Lot and Garonne. For several miles along the lower reaches of the Lot, where it flows through a rich alluvial plain, and in the country immediately adjacent to the spot where it enters the Garonne, is grown the fruit which yields, when specially prepared, the product known as French Plums. For over 100 years the industry has been fixed in this locality, and still, with the exception of a valley in Servia, there is no other place where the same trees are cultivated on a large scale. The tree is called *Prunier d'ente*. *Enter* is an old word meaning to graft, and it is simply so called because this particular variety was formerly the only Plum in the district that was ever grafted. Now there are practically no Plums other than the Prunes *d'ente* grown in the neighbourhood. Higher up the Garonne round the old town of Agen, and in other parts of Southern France, other Plums are largely grown, such as the *Prunier Commun*, the *Ste. Catherine*, and others, and the fruit is treated similarly to that of the *Prunier d'ente*, but the produce is very inferior and only suitable for stewing; and, I believe, that nowhere else except in the Servian valley is the true *Prune d'ente* at present grown, though many experiments have been tried with other varieties. None have yet been discovered that will yield the best qualities of French Plums. It is rather capricious in its growth, for its area of cultivation does not extend very far from the river bank. It appears to delight in a deep alluvial soil of a rather sandy nature, but which contains a sufficiency of clay to make it very retentive of moisture. The centre of the French Plum district may be said to be at Clariac, a quaint little old-fashioned town built on a steep hillside overlooking the Lot, almost more Spanish than French, its houses shaded from the fierce southern sun with wide outspreading leaves and flower-clad balconies. Here I was most hospitably received and entertained by M. Gajac.

In this and the neighbouring communes the metayer system has long been in full operation, and it appears to work well and harmoniously. The owner of the land engages the metayer and supplies all the stock and implements required for the holding. He also keeps in repair the house and buildings. The metayer also finds the whole of the labour except such extra labour as is needed for the harvest. He has during the year entire control of the farm, and buys and sells, subject if required to the approbation of the owner. He renders account of all produce from the holding consumed by himself and his family, and at the end of the year the balance of profit is divided equally between him and the owner. During the last few years the metayers have fared badly. The phylloxera has devastated the vineyards, and sad it is to see acres and acres of land excellent for the growth of Grapes, but fit for little else, now deprived of those crops which, till recently, so well repaid the cost of cultivation. The holdings vary in extent from ten acres to fifty or sixty, and on every holding in the lowlands are to be seen rows of the *prunier d'ente*, separated from each other by long strips of cultivated land, where the mild fawn-coloured oxen lazily drag the most old fashioned and primitive implements over the easily

broken soil. The Plums are long shaped, the stalk end being much the more pointed; the colour is red, deepening into a rich violet as the Plum ripens; the skin is extremely tough without being thick or hard; the flesh very firm, containing a large amount of saccharine; the specific gravity much greater than that of several varieties of English Plums with which I have made comparison. The tree is a very slow grower, requiring ten years to bring it into full bear, though I saw some trees of six years old which were favourably situated carrying a good crop.

The fruit matures slowly and is not ripe till long after all other fruit in the district—Apricots, Peaches, Green Gages—have been gathered. All the apparatus required for the process consists of trays, or *clais*, as they are called, and two or more ovens. The *clais* are made either of wickerwork or wood, and are round or triangular. They are deep enough to carry a single layer of Plums. The sides are high enough to allow of their being placed upon each other without crushing the Plums, when they are not in the ovens. Every morning each metayer looks over his trees, picks the fruit that is ripe, just before the flesh begins to soften. The Plums are brought to the homestead, placed one layer thick in the *clais*, which are first put for an hour or two in the sun or in a current of air, and then laid on the floor of the oven. These ovens, or "fours," are simply just like ordinary bread ovens; they are usually built in pairs, each one about 10 feet long and 4 feet wide inside, and are heated by simply burning a certain quantity of wood inside them. In some few places *etuves*, or kilns, are substituted for the "fours." These are closets of variable dimensions fitted with a small furnace from which flues pass under and up the side of the closet, and also with various appliances for holding the *clais*. There seems to be a preference for the fours, though the *etuves* are simple and more convenient in every way. When the fresh fruit is first put in the temperature should be about 100° Fahrenheit. In the course of a few hours the Plums assume a curious puffy appearance, and if the heat is too great they will burst, a result most carefully to be avoided. They are taken out of the oven, cooled, and again put in with the temperature at about 135°, again withdrawn and cooled, and this time the fruit is turned by placing an empty *clais* upside down over a full one, and turning them over together. They are again put into the oven, this time the heat being raised to about 170°. This operation is repeated until all the Plums are completely preserved. Some dry more rapidly than others, and they are picked out and placed in other *clais* as they are ready. The more slowly the whole operation is performed the better, and the oftener the Plums are put into the four the higher will be the quality of the product. When ready the Plums are sorted out into various grades according to the number (30, 40, 50, 60, and so on up to 130 or more) that it will require to weigh a French pound, for curiously enough the old measure is adhered to and not the more modern kilogramme. They are then put into sacks and carried each week, or oftener, to the markets. Here the merchants come and buy, paying prices varying according to the number of the Plums required to weigh a pound. Thirty to the pound would be worth about 120 francs the 100 pounds; 40 to the pound 100 francs per 100 pounds, and so on down to the very lowest grades, which are not worth more than 15 francs. The merchants convey their purchases to large, cool, airy warehouses, where the fruit is thrown into large bins. Women seated at long tables are then employed sorting it over again much more carefully than before. The various grades are then packed separately in casks and sent to Bordeaux, where the finer qualities are unpacked and neatly laid in baskets or boxes. The inferior grades are simply exported in bulk.

I traversed day after day a considerable area of the Plum district, and everywhere saw the same Plum trees growing and the fruit being treated in the same manner. Everywhere, too, I met with the same good-humoured courtesy. It is a primitive out-of-the-way place very seldom visited by strangers, and much wonder was often expressed at my having travelled so far to learn that of which they could hardly conceive that anybody should be ignorant. It is an interesting country, full of memories of the past, and it is curious to think that long years ago the whole district belonged for over three centuries to the English Crown. I said to one metayer that perhaps his ancestors and mine had been there once side by side together. "Ah, Monsieur," he said, "if they were I don't expect your ancestors and mine sat down very comfortably together." A very fertile country it is too, blessed with a glorious climate, and were not our time to day to be devoted entirely to fruit I could tell of many crops I saw there being cultivated, amongst which Tobacco holds a very prominent place.

The lessons I learnt were these, that it is very easy indeed to manufacture French Plums, but you cannot make a silk purse out of a sow's ear, and there is one proviso, which is that you have got the right fruit to deal with, but failing this it is perfectly impossible to make the higher grades of French Plums. Secondly, that we have not got in England the true *prune d'ente* or any Plum really nearly resembling it. However, I determined on my return to make the best attempt I could with our Westbury Plums. Unfortunately it was a most unfavourable season, for the fruit in England never ripened properly, and the continued absence of warm sunshine reduced to very small proportions the amount of saccharine—an ingredient most vitally necessary—so that the experiment was made under avowedly unfavourable auspices. I have at my brickworks at Mitcheldean a special kiln for burning pottery and terra cotta. This kiln has some points of similarity with a French fruit *etuve*, only much better. It is fired with a special gas produced on the spot, and the flame circulates in a hollow wall round the kiln, but never enters it. It can be cut off at any moment, and

the temperature regulated at will. Of course being made for terra cotta its shape and form is not convenient for drying Plums, but it afforded ample evidence that kilns built on this principle, but specially modified, would answer admirably for fruit-drying purposes. I tried several kinds of Plums, amongst others the Early Prolific, Blaisdon Red, Victoria, and Black Diamond, but every Plum I tried was deficient in all the three characteristics of the *prune d'ente*—toughness of skin, solidity of flesh, and abundance of saccharine. Some failed altogether, and even those which yielded a moderately fair result had to be treated with extraordinary care to avoid the bursting of the skin and consequent escape of the juice. They had to be put many times into the kiln, and the finishing temperature had to be arrived at very gradually; and even then I unfortunately spoilt from a too high temperature several claufuls of Plums, which I was preparing in an ordinary bread oven at Westbury. The Plum season was a short one this year, and unless picked quite green so many rotted before they were really ripe, owing to the damp and rain. So that with the time and means at my disposal I was only able to produce a very limited number of Plums. Those giving the best results were the Blaisdon Red, the Black Diamond, and the Victoria.

The deductions I should draw from my observations and experiments may, I think, be summarised as follows:—

1, That whilst we do not cultivate in this country at least the true *prunier d'ente*, nor any tree bearing fruit at all similar to it, it is very doubtful whether it would really succeed if introduced. In its native country, where the summers are longer, much warmer, and more reliable than with us, it is the earliest to bloom and the latest to ripen of all Plums. The department of the Lot and Garonne is about 450 miles almost due south of Reading, a distance sufficient to make a very material difference in climatic influences. M. Gajac, though he had never been in England, and could not speak a word of English, knew something of the valley of the Severn, and thought that the influence of the Gulf Stream on our western coasts and the daily influx of warm tidal water up the river might compensate for our more northerly latitude. That these influences do produce considerable effect is certain, but not sufficient to place us on anything like an equality with the district 450 miles nearer the equator. I have no doubt the trees would grow well and bear fruit, but I do doubt most extremely whether they would produce a fruit capable of conversion into a good quality of French Plum, though it would be capable of making very excellent pruneaux in most if not all seasons. I last winter had sent me from Orleans a dozen trees which were supposed to be the true French Plum tree. I did not then know as much about the matter as I do now, and I much doubt whether these trees are the right ones. They called them at Orleans *Pruniers d'Agen*, and I expect they really represent the *Pruniers Communs* to which I have referred. There are now being sent me from Clairac a score of the true *pruniers d'ente*, so that I may test experimentally whether they will thrive in our district. I may mention that at Clairac they always graft at the foot of the tree. They say the winters are so rough that there is much less chance of damage from the wind than if the graft were several feet from the ground.

2, That though none of our existing Plums will yield best French Plums, we can produce pruneaux, which are not without merit. Whether it would be a lucrative operation is not an easy question to answer. We have to bear in mind that it will require nearly 4 lbs. of our home varieties to make 1 lb. of pruneaux. In other words, assuming the value of the raw fruit to be 1d. per lb., it would take 4d. worth of fruit to make 1 lb. of pruneaux, and I think this would have to sell at 5d. per lb. to make the manufacture profitable.

3, A factory could not be started solely for the manufacture of pruneaux, because the busy time would be so small a proportion of the whole year that it could hardly be rendered remunerative; moreover the raw fruit would bear but little travelling, and so could not well be brought from any great distance. It has to be quite ripe and yet must not be at all bruised, and the skin must not be the least broken. A factory might encourage the erection and maintenance of ovens and kilns in different localities, and in fact the earlier stages of manufacture might be carried out in such localities themselves, and the process be subsequently completed at the factory. Such a plan would also have the advantage of extending the annual period of life at the factory. It might also be possible to store the raw fruit in cool chambers at the factory and dry it at leisure, but I doubt this. A factory in fact, to be successful, must embrace other operations beside drying Plums.

4, That the principle of the gas-kilns I have described is admirably adapted for fruit-drying purposes. Such kilns erected in pairs or in sets of four would not be costly, and would dry a great quantity of fruit. Not only Plums, but Pears and Apples, were dried abroad, and such work would have the advantage of coming in after the Plum season had expired. It is, however, I think, to individual growers we must look if any industry, such as French Plum manufacture, is to succeed. It is essentially an industry for small holdings, and no factory can itself carry out the work on a large scale, though it may materially assist in many ways. If it took no part in the manufacture it might well take the place of the merchant in France; might purchase the Plums direct from the growers, grade, store, and market them; but individual growers must take up the industry. If anyone possessing a suitable piece of ground for even fifty trees, giving them plenty of room for light and air, will plant *pruniers d'ente*, I am satisfied it will pay him well to make and use an oven; and though he will probably not make "French Plums," he will certainly make most excellent pruneaux, and sell them at a good price. Whether the industry will succeed if

simply applied to our native growths is a very much more doubtful point. The amount of extra trouble, care and attention the process will require in consequence of the fruit lacking the necessary characteristics will increase the cost of manufacture and reduce the value of the produce. I think myself that it is in other ways that we must look to dispose of the produce of our existing varieties of Plums, and for some at any rate of these ways a factory is probably an essential element of success.

CHRYSANTHEMUM SHOWS.

MARGATE.—NOVEMBER 21ST AND 22ND.

THE Isle of Thanet Chrysanthemum Society has only been established two years, and by sheer hard work and excellent organisation the Society has made remarkable progress. The Exhibition held in the Hall by the Sea on the above dates was very satisfactory. The first prize for a group of miscellaneous plants arranged for effect went to Mr. Gosden, gardener to J. Atkinson, Esq., Albert House, Westbrook, for a fine group lightly arranged. Second, Mr. Roberts, gardener to T. Sebag Montefiore, Esq., East Cliff Lodge, Ramsgate, who ran the first group very close. Trained plants were arranged down the whole of one side of the hall. In the class for six specimen plants, Mr. Fairweather, gardener to W. Tarrett, Esq., Westgate-on-Sea, was first with fine plants of Mrs. G. Rundle, Pink Christine, and others. Mr. J. Cornford was a very good second, and Mr. Iles third. For a single Japanese specimen Mr. Fairweather was again first with a superb plant of Peter the Great. On the opposite side of the hall were the groups of Chrysanthemums arranged for effect. There were eight entries, and the competition most keen; so close were the first and second that some difficulty was experienced in separating them; the post of honour, however, fell to Mr. Cornford, gardener to H. P. P. Cotton, Esq., Quex Park. Mr. E. Bishop second, and Mr. F. Roberts third; this group was bright and remarkably fresh. A grand group of cut down plants was staged by Mr. W. Jarman, gardener to T. Farmer, Esq., Chapel Hill, Margate, not for competition, attracted considerable attention.

The cut blooms throughout the Show were of first quality. In the class for twenty-four incurved flowers, Mr. Cornford was first with good blooms, including Golden Empress of India, Emily Dale, Jeanne d'Are, Pink Perfection, &c. Mr. Fairweather second, and Mr. J. Gaines third. For twelve incurved Mr. Fairweather came first with grand blooms of Empress of India, Cherub and Empress Eugénie. Mr. Cornford second. Mr. Fairweather was again first in the classes for six incurved and for three incurved alike, exhibiting three perfect blooms of Empress of India. The Japanese classes were well filled, and for twenty-four blooms Mr. Cornford was first with good blooms of Moonlight, Baronne de Prailly, Belle Paule, &c. Mr. Fairweather second with Comte de Germiny, Gloriosum and Grandiflorum. For six Japanese Mr. Fairweather was again first with the finest half-dozen blooms in the Show, amongst them being Madame C. Audiguier, Gloriosum and Grandiflorum. Mr. Cornford second, and Mr. T. Hunt third. In the open class for thirty-six blooms Mr. Skinner of East Sutton Park, Staplehurst, was first with grand flowers of Edwin Molyneux, Gloriosum, Meg Merrilies, Ralph Brocklebank, Mdlle. Laeroix, Mr. C. H. Wheeler, Lady Lawrence, Empress of India, Emily Dale, Bronze Queen of England, C. Gibson, and Mrs. Norman Davis. Messrs. W. Ray & Co. of Teynham were a good second.

Mr. Fred. T. Hart of Ospringe Road Nursery, Faversham, staged some grand blooms not for competition, the most prominent amongst them being Edwin Molyneux, Amy Furze, Mdlle. Paule Datour, Mir, Madame Pages, Martha Harding, Lady Lawrence, Florence Percy, &c.

The fruit and vegetables were of excellent quality; amongst the prizewinners were Mr. F. Miller, Mr. T. Lake, Mr. A. Croucher, Mr. T. Cornford, and Mr. Barber.

WOKINGHAM.—NOVEMBER 21ST AND 22ND.

THIS small but flourishing Society held its fourth annual Show in the Drill Hall, Wokingham, on Tuesday and Wednesday, November 21st and 22nd. The show of cut blooms was good, several well-known exhibitors competing in the open classes. In the leading class for twelve incurved, distinct varieties, Mr. W. Lane, gardener to Miss J. D. Smith, King's Ride, Ascot, was first with a good even stand, very bright and fresh. Baek row—Empress of India, Alfred Salter, Golden Empress, and Lord Alcester. Second row—Princess of Wales, Jeanne d'Are, Princess Teek, and Jardin des Plantes. Front row—Yellow Perfection, Angelina, Isabella Bott, and Lady Carey. Mr. Allen, gardener to Sir G. Russell, Swallowfield Park, was a close second; Mr. Hughes, gardener to H. F. Paravicini, Heathfield, Ascot, third.

Mr. Lane was also successful with twelve Japanese, staging good blooms of the following varieties:—Baek row—Madame C. Audiguier, Lady Trevor Lawrence, Belle Paule, and Gloriosum. Second row—Mr. H. Cannell, J. Délaux, Thunberg, and Madame J. Laing. Front row—Mr. H. Wellam, Criterion, M. Brunet, Mdlle. Laeroix. Mr. Allen was second; Mr. Popple, gardener to Lady Stephney, Ascot, third. For six reflexed, Mr. Popple was first; Mr. Lane, second; Mr. Hughes, third. Groups were poor. Mr. Sinclair, gardener to the Marchioness of Downshire, Easthampstead Park, was first; F. M. Wescott, Esq., second; and Mr. Ashman, Billingbear Park, third.

Messrs. Sutton's special prizes for vegetables brought a fine competition. Mr. Wilks, Holly Court, was first; Mr. Poppel, second; and Mr. W. Townsend, third; and Mr. W. Ball, fourth. Cyclamens were well

shown by Mr. Wilks. For six table plants Mr. Sinclair was first, Mr. Wilks second, and Mr. Ashman third.

A COTTAGERS' SHOW AT RYDE, ISLE OF WIGHT.—NOVEMBER 27TH.

It is not often that cottagers have the honour of a show all to themselves. A few classes at the end of the schedule, and the exhibits placed in the most inconspicuous part of the hall, are the usual allotments to this section of exhibitors. The name of cottagers is often made a handle of in soliciting subscriptions to encourage the more general cultivation of the flower, but their blooms sink into insignificance when exhibited with the lions produced by some of our great exhibitors. Not so in Ryde. In the words of the Mayor of the town, R. Colenutt, Esq., when he opened the Exhibition on the above date—"Last year the exhibits of the cottagers were so numerous and so good that the Committee thought they merited a separate exhibition, and the results had justified the steps they had taken, for many of the exhibits would compare favourably with those shown by professional gardeners." The collections of Chrysanthemum blooms, the baskets of blooms arranged with foliage, and the floral designs were an exhibition in themselves, and some of the cut blooms were of good substantial quality, and showed good cultivation. For the best collection of cut blooms, Mr. H. Gattrell, Ryde, was first for a fine box of fresh blooms of excellent varieties, the back row being raised up very effectively; Mr. G. West, Oakfield, being second; and Mrs. H. Orchard, Ryde, third, with excellent lots. For twelve incurved, not less than six varieties, Mr. O. Dibbens was first with good but rather rough flowers; Mr. G. Attrill, St. Helens, second; Mr. G. Coombes, Swanmore, third; and for twelve Japanese, six varieties, Mr. O. Dibbens was again first, showing a good Val d'Andorre and Boule d'Or; Mr. A. Wade, St. Helens, second; and Mr. Taplin, Ryde, third. For twelve blooms, distinct, any section, Mr. H. Gattrell was first; Mr. Attrill, St. Helens, a good second; Mr. G. Coombes third; and Mr. Young, St. Helens, was highly commended for a meritorious stand. There was not much competition for eighteen incurved, six varieties; and the second prize only was awarded to H. Gattrell. For six blooms, three varieties, Mr. A. Wade was awarded first, Mr. J. Taplin second, and Mr. J. Niblett, Niton, third; and for six blooms, reflexed, Mr. O. Dibbens was awarded first. The same exhibitor was also first for six blooms, any variety, with A. Wade second, and Mr. J. Woodford, Ryde, third.

The competition for the special prizes offered by Mr. Councillor J. D. Brook for the best basket of Chrysanthemums with foliage, was sufficient to fill the centre of the table the whole length of the hall. They were raised above the cut blooms on a covered board, and although some were too heavily packed with flowers, they, as a whole, were very effective, and the Committee were very thankful to accept the donor's offer to extend the prizes for their encouragement. Miss Orchard, High Park, was awarded first for a light sloping side basket, with the decorated handle carried well above the body. Second, Mr. E. C. Williams, Ryde; extra second, Mr. J. Niblett, Niton, and third, Mrs. E. Brading, Wooton Bridge; extra, Mr. C. Prince, Haven Street, and highly commended, Mr. J. Woodford and H. Gattrell. For the special prizes offered for the best floral device or design there were nine exhibitors, making in itself a very attractive exhibition, the majority showing great taste in the arrangement of colour, and ingenuity in the designs. Amongst the exhibitors two were by trade carpenters, one a blacksmith, and one a milkman, and much credit is due for their patience and skill displayed in their arrangements. The Committee again offered to extend the prizes in this class, which was merited. Mr. C. Kent, Haylands, was awarded the first prize for a design measuring 2 feet 10 inches by 3 feet 10 inches, the designs being a basket of Chrysanthemums, the basket made of yellow Chrysanthemums and the body and handle filled with coloured varieties. Around the outside of the melallion, formed of moss, was a motto and various ornamental scrolls made with Pompons and other Chrysanthemums. The second was awarded to Mr. G. Hayden, Haven Street, whose design was the dial of a clock very well done; extra second, Mr. C. Prince, with a star; third, Mr. G. H. Kent, Haylands; extra third, Mr. E. Salter, Swanmore; and fourth, Mr. F. C. Nunn, West Street. Messrs. C. Frampton and G. Stainer, Ryde, were highly commended for excellent designs, one using Holly berries in the device of the arms of the borough of Ryde. Mr. A. Wade, St. Helens, was the most successful exhibitor in the plant class, showing rather tall bushes with good heads of bloom, but the majority of the plants were too tall to be effective. There were also prizes offered for baskets arranged with berries, autumn foliage, and Ferns, but although very pretty they were not quite so good as was shown at the previous Exhibition. Messrs. H. Lipscombe, Haven Street, E. G. Brett, and Mrs. Kent, were the successful exhibitors. A fine stand of blooms put up in triples and exhibited by J. D. Brook, Esq., formed an attractive feature in the Exhibition, in which he takes an active part in conjunction with Mr. J. Eley, the Secretary, to make the Ryde flower shows a popular and successful gathering.

MANCHESTER.—NOVEMBER 27TH AND 28TH.

THE Exhibition, as usual, was held in the Town Hall, and the weather during the early part of the first day could not have proved more unsuitable. The Exhibition was not large; it was, however, very attractive. The schedule only comprised eleven classes, and these were well filled. Miscellaneous plants were numerous, and added materially to the effect of the Show.

Five classes were devoted to cut blooms, and they were well filled, but the blooms, with the exception of the first-prize collections, were

below the average. For twenty-four incurved Mr. Lambert, gardener to Col. Wingfield, Onslow Hall, Shrewsbury, was first with neat fresh examples of (back row) Empress of India, Alfred Salter, Lord Aleester, a sport of the last named being similar to Queen of England at the base and Lord Aleester towards the centre, Lord Wolseley, Golden Empress, Jeanne d'Arc, and Queen of England. Middle row—John Salter, Princess of Teck, Empress Eugénie, Prince Alfred, Princess of Wales, Beauty, Mrs. N. Davies, and Pink Venus. Front row—Jardin des Plantes, Lady Slade, Mrs. Heale, Cherub, Baron Beust, Mrs. C. Gibson, Eve, and Barbara. Mr. J. Carling, Woolton, was second with fair blooms rather open in the centre. Third S. Shirley, Esq., Withington, with much smaller blooms. For twelve incurved the first-named exhibitor was again first with blooms equal to those in the preceding class. Mr. J. Walker, Vernon Park, Stockport, second, and Mr. Goodacre, gardener to the Earl of Harrington, Elvaston, Derby, third. Four collections were staged.

For twenty-four Japanese Mr. Lambert was again first with fresh bright flowers of good size. The varieties were, back row—Japonais, M. Astorg, Ralph Brocklebank, Dormillion, Meg Merrilies, Gloriosum, Fair Maid of Guernsey, and Madame C. Audiguier. Middle row—Comtesse de Beauregarde, Criterion, Val d'Andorre, Avalanche, Jeanne Délaux, Madame J. Laing, Golden Dragon, and Mdle. Laeroix. Front row—E. Molynieux, Album Plenum, Duchess of Albany, Belle Paule, L'Or du Japon, Hiver Fleuri, Carew Underwood, and Madame de Sevin. Mr. J. Carling, Woolton, was second with lighter blooms, and Mr. J. Walker and Mr. Goodacre equal thirds. Five collections were staged. For twelve blooms Mr. Lambert was again first with capital specimens, Mr. Goodacre second, and N. A. Earle, Esq., Kersal, third. The same number of collections were again staged. In the remaining class for the best collection of reflexed Pompons, Anemone, large flowering Pompons, and Japanese Anemones only two collections were staged, and the winners were J. Lamb, Esq., Bolton; and D. McClure, Esq., Heaton Mersey.

For the best collection of stove and greenhouse flowers only two collections were staged, but they were excellent, and the chief award fell to A. Heine, Esq., Fallowfield, who staged good bunches of a large number of Orchids on a groundwork of Adiantum freely intermixed with bunches of stove and greenhouse flowers, the effect being all that could be desired. Thos. Staller, Esq., was placed second with a choice collection of Orchid blooms. For one centrepiece suitable for table decoration S. Lond, Esq., Ashton Mersey, was placed first for a very light arrangement. For one bouquet Mr. A. Heine was deservedly placed first, and Mr. Goodacre second.

Chrysanthemum plants in pots were not so good as they are usually seen at Manchester. For nine large flowering varieties, N. A. Earle, Esq., was first with good examples of culture; H. Galbraith, Esq., second; and W. Leak, Esq., Alexandra Park, third. For six Japanese the same exhibitor was again first. For six Pompons, R. Hardwick, Esq., was first.

Mr. Gleeson, gardener to the Duke of Newcastle, Clumber, contributed twelve remarkably fine Pines, for which the Society's gold medal was awarded. Messrs. R. Smith & Co., Worcester, had a first-class commendation for a collection of Apples, and the same award went to Messrs. Dicksons, Limited, Chester, for seventy-four dishes of Apples. Messrs. Dickson & Robinson, Manchester, staged Cyclamen, Roman Hyacinths, and Heaths in capital condition. Messrs. Brown & Tait a very similar and equally praiseworthy exhibit, for which first-class commendations were awarded. Messrs. Clibran & Sons, Oldfield Nursery, Altrincham, staged cut Pelargoniums, and a collection of flowering and foliage plants, also a large collection of Chrysanthemums of various sections, a first-class certificate being awarded them for a sport from Criterion. J. Robino, Esq., had a first-class certificate for Lycaste Skinneri alba with three fine flowers. Mr. Mason, florist, Manchester, contributed wreaths, bouquets, and crosses; and Mrs. Barlow, Skimdda-hir Llandudno, a collection of flowers cut from her garden outside. The variety and freshness of the flowers for this season of the year were remarkable. Mr. Bruce Findlay sent from the Botanic Gardens a good number of plants, both flowering and foliage; most conspicuous was a group of Sarraenia Drummondii alba, which were in splendid condition.

ALNWICK.

THE second annual Show of Chrysanthemums, fruit, and flowers in connection with the above Society was held in the Corn Exchange on Thursday last. The dimensions of the Exhibition in the department of pot plants showed a considerable falling off from last year, but this finds ample explanation in the lateness of the season, consequent on the want of sunshine which has characterised the last few weeks. Another unfortunate circumstance affecting local competitors in connection with this year's Show lay in the fact of its being held between a week and a fortnight earlier than it was last year, the result being that local growers, notably Mr. D. P. Bell of Clive House, had many plants not sufficiently matured to enter the competition. The exhibits were neatly arranged laterally around the hall, a stand also running lengthwise through the centre of the room. This central display consisted of cut flowers and fruit, the quality of which was not inferior to that of the exhibits shown in these two departments last year, and the aspect of the whole was exceedingly pretty. Vegetables were also good. Amongst the exhibits not for competition was a fine stand of plants by Mr. T. B. Morton, nurseryman, Darlington; a beautiful collection of cut blooms by Messrs. Ferguson & Munroe, nurserymen, Edinburgh; a splendid display of vegetables by Mr. J. T. Scott, Alnwick, and a numerous and

highly creditable exhibition of Apples by Mr. James Thomson, Shawdon. The hall was neatly decorated with plants from the Castle Gardens, under the supervision of Mr. Geo. Harris.

The following Committee have worked arduously for the success of the Show:—Messrs. M. Armstrong, J. Simpson, W. Bell, G. Harris, J. T. Stott, D. P. Bell, M. Swan. The duties of Treasurer were ably carried out by Mr. G. H. Thompson, and those of Secretary by Messrs. G. Simpson and J. Ferguson.

The chief prizes for plants were won by Mr. Paul Blanchard, Sunniford Park; for cut blooms by Messrs. J. Short, T. J. Wheeler, D. P. Bell, J. Pringle, and G. Shotton. For miscellaneous exhibits, fruits, and vegetables, the prizes were accorded to Messrs. Wheeler, Blanchard, Pringle, Finch, Bell, Oliver, Robson, A. McIntosh, Stott, and Logan.

ECCLES.—NOVEMBER 30TH AND DECEMBER 1ST.

THIS young Society held their second Exhibition in the Town Hall, and it was in every respect a very good one, and considerably in advance of the one held last year. The Committee increased the number of classes and prize money consequent on their first exhibition proving such a success financially. The schedule comprised forty-six classes, twenty being open to all, sixteen open to amateurs, and the remainder devoted to the members of the Patricroft Linnæan Society.

Cut blooms were more numerous and of better quality than we had expected to have found them. For eighteen blooms, half incurved and half Japanese, Mr. J. Lamhert, gardener to Col. Wingfield, Onslow Hall, Shrewsbury, was the only exhibitor, and staged capital blooms of *Gloriosum*, *Madame J. Laing*, *Fair Maid of Guernsey*, *Madame C. Audiguier*, *Mdlle. Lacroix*, *Criterion*, *L'Or du Japon*, *Madame de Sevin*, and *M. Astorg*; incurved, *Golden Empress*, *Queen of England*, *Lord Alcester*, *Princess of Wales*, *Alfred Salter*, *Jardin des Plantes*, *Princess of Teck*, *Mrs. C. Gibson*, and a sport from *Lord Alcester*. For twelve incurved varieties the same exhibitor was again first with grand flowers of the sport from *Lord Alcester*, *Queen of England*, *Alfred Salter*, *Empress of India*, *Jeanne d'Arc*, *Princess of Teck*, *Lord Alcester*, *Golden Empress*, *Barbara*, *Jardin des Plantes*, *Eve* and *Princess of Teck*. Mr. J. Walker was second with smaller and flatter blooms, and A. N. Earle, Esq., third. In the corresponding class for twelve Japanese Mr. J. Lambert was again first with fresh, fair sized blooms of *Baronne de Prailly*, *Jeanne Délaux*, *Fair Maid of Guernsey*, *Dormillion*, *Japonais*, *Criterion*, *Val d'Andorre*, *Madame J. Laing*, *Duke of Albany*, *E. Molyneux*, *Gloriosum*, and *M. Astorg*. Mr. J. Walker was again second, and A. Knowles, Esq., third. For twelve blooms, six Japanese and six incurved, the winners were the same as in the preceding class. For nine blooms, three Japanese, three incurved and three *Anemone*, Mr. J. Walker was first, and also for six blooms of *Anemones*. In the amateur class for eighteen blooms, any variety, staged for effect, Mr. H. Huber was first, and Mr. W. Crawshaw second, both showing well. For twelve blooms, six Japanese and six incurved, Mr. Crawshaw again took the lead, followed closely by Mr. Royles. For six incurved Mr. Crawshaw was first, and also for six Japanese. For twelve blooms, half Japanese and half incurved, in the third section, Mr. H. Huber took the lead. For six incurved Mr. R. Johnson, and the same exhibitor was first for six Japanese.

Chrysanthemums in pots were considerably better than is the case at most exhibitions. Those in the open classes were all that could be desired, while those in the amateurs' sections were highly praiseworthy. For a group of plants, any varieties, arranged for effect, space not to exceed 9 feet by 6 feet, four groups were contributed. G. H. Leigh, Esq., was placed first with grand examples of culture; none of the plants exceeded 3 feet high, and many of them not more than 2, with dark healthy foliage to the base, the plants carrying six and eight good blooms each. N. A. Earle, Esq., was a close second with most of the plants equal to those in the first collection. Mr. W. Russell was placed third. For six plants, large flowering varieties, Japanese excluded, Mr. N. A. Earle was well first with excellent examples of *Emily Dale*, *Queen of England*, *Mr. Bunn*, *Empress of India*, *Barbara*, and *Princess of Teck*. J. Reddaway, Esq., was placed second with rather taller plants. For six Japanese Mr. N. A. Earle took the lead with well grown plants of *L'Adorable*, *Elaine*, *E. Molyneux*, and *Val d'Andorre*. In the corresponding class for six plants, three incurved, and the remainder Japanese, Mr. N. A. Earle was again first, and Mr. J. Reddaway second. For three *Pompons* Mr. Earle was again first with fair plants. For a group of miscellaneous plants arranged for effect, space not exceed 7 feet by 5 feet, Mr. Thos. Agnew, Eccles, was well first with the most tastefully arranged group we have seen for a long time. Mr. N. A. Earle was placed second with a very good arrangement. Table plants were very good, being light and of a suitable size for that purpose, Mr. J. Fountain was placed first. Mr. F. Reddaway took the lead for Roman Hyacinths, which were well shown. Mr. N. A. Earle was first, *Poinsettias*, good pots full, with fair sized bracts. *Primulas* were below the average, Mr. N. A. Earle was deservedly accorded the premier position. The same exhibitor was also first for *Calanthes*.

Miscellaneous exhibits were numerous and added largely to the attractiveness of the Exhibition. Messrs. Clibran & Son, Oldfield Nursery, Altrincham, staged several hundred blooms of *Chrysanthemums*, also boxes of *Pelargoniums* and miscellaneous collection of plants. Messrs. R. Smith & Co., Worcester, contributed a collection of Apples and Pears, about twenty-six dishes of fine fruit; Mr. Thos. Agnew, Eccles, a number of *Crotons* and Palms, large healthy plants; Messrs. Dickson, Brown & Tait, Manchester, splendid boxes of Roman Hyacinths, a few *Cyclamen*, and other plants; Messrs. Dickson & Robinson, Man-

chester, *Erica hyemalis*, *Cyclamens*, and small Palms; Mr. W. Grange, florist, Eccles, contributed a table of Grapes, Pines, Apples, Pears, and Mushrooms, intermixed with flowering and foliage decorative plants; Mr. J. Derbyshire, fruit grower, Liverpool Road, Patricroft, a collection of Apples.

It will be seen from the brief outline given that the Exhibition was a thoroughly representative one, and highly creditable to all who took part in its management.

HARDWOODED PLANTS AT CHELTENHAM.

ONLY those who follow out exhibiting week by week fully realise the great amount of hard work incurred by competitors. By continued practice, however, the anxiety is considerably lessened. The skilled exhibitor knows to a nicety what plants will be ready for this or that show on a particular day; whether this plant will need retarding, or that one pushing on, to be in condition at the right moment. Plants are judged upon their merits at the time they are viewed by the judges, and not what they were a week previous, or what they may be a week hence. From time to time, for years past, the writer has had many pleasant conversations with Mr. Cypher of Cheltenham, whose fame as an exhibitor is widely known in England. Those of your readers who frequent our larger exhibitions cannot fail to notice the clean, fresh, healthy appearance of Mr. Cypher's plants whenever seen, so of this I will say nothing, but turn briefly to the specimens on their return home, or in other words—"after the battle."

The collection of hardwooded plants grown at Cheltenham for exhibition purposes is, perhaps, one of the finest extant, many of the individual examples reflecting the highest possible credit on the cultural skill which has brought them to such perfection. Some of these plants, particularly the hardwooded Heaths, do duty at a series of exhibitions during the period in which they are in flower. In taking these from place to place they are of necessity subjected to a variety of change, both of temperature as well as in the supplies and the quality of the water which must of necessity be given them. Nothing is more conducive to making some of these fastidious *Ericas* present a sickly appearance than changes of this kind; and while a thorough knowledge of their usual behaviour under such conditions reduces losses to a minimum, yet plants, and particularly hardwooded Heaths, that have attained the age of thirty or even fifty years, will and do become unhealthy now and then, despite all attempts to the contrary. It is only those with keen judgment, decisive action, and an ever-watchful eye that can hope to become successful cultivators of such plants. One of the first steps taken by Mr. Cypher after the plants have done their season's work is to clear them of all their flowers, in itself a rest, if momentary, to the plants themselves. Though a tedious operation, this picking over the plants is soon accomplished by practised fingers, and the plants are again ready to make their new growth for flowering the next year. When it is known that some of these grand specimens are fully 6 feet high and as much through, it is obvious that they must when well flowered carry an enormous mass of bloom; and at any time they are well worth inspecting, for cleanliness, health and vigour are apparent with everything to which Mr. Cypher puts his hand. Some of the more prominent of these giant Heaths are *E. Cavendishiana*, *E. depressa*, *E. æmula*, *E. ampullacea Barnesii*, *E. Iveryana*, *E. tubiformis*, *E. Aitoniana* *Turnbullii*, *E. Austiniana*, *E. ferruginea major*, *E. Parmentieriana rosea*, *E. McNabiana*, and *E. Marnockiana*. Most of the above are in fine specimen form, of a vigorous uniform growth, which tells its own tale. Some grand specimens of *E. Cavendishiana* are coming on, clean vigorous pieces, which in all probability will be seen in the first half of the ensuing year. These are but young examples, but they are excellent specimens, and serve to illustrate the means employed to keep a stock of fair-sized plants, for although there are giants, and it is known exactly when and where they will be needed, there are also quantities of admirably grown compact plants which present a freshness and vigour seldom seen.

Then there are *Aphelaxes*, *Phænozonas*, *Aerophyllum venosum*, a most difficult plant to manage, with *Allamandas*, *Draconophyllum gracile*, *Statice*, and others. Particularly noticeable was one fine example of the latter for its superb colour. *Pimeleas*, again, are here well done, and seemingly perfectly happy; a large piece of *P. spectabilis* was 5 feet through. It is specimens of this size that require really good judgment and every care to keep them in good health. Of *Bougainvillea glabra* there were some fine pieces splendidly flowered; but these, unlike many plants grown here, seem to take affront at being moved about, and soon take cold, so much so that the same plant will not do for two shows in successive weeks, as the majority of the buds fall off after the fourth or fifth day, no doubt the result of a chill at the roots.

Both *Crotons* and *Ixoras* are grown in large numbers of the best varieties. Mr. Cypher enforces his *Crotons* in a way which always makes them conspicuous at exhibitions, and plenty of heat, full sun, close to the glass, and abundance of moisture are the lines worked upon. A severe system of pruning is always indulged in for both, and that as soon as the plants can be dispensed with; after this they are kept moderately dry at the root till they show signs of breaking, being encouraged the while by light syringings. Apart from this class of plants, many rare specimen Palms and Cycads are to be seen, and gigantic specimens too are some of them. A good deal of attention is given to *Anthuriums*, all the best kinds being grown. A *Cypheri* may well be styled the prince among this group, but as yet it is barely

known. It eclipses all others in size, substance, and colour. At present the stock is limited, hardly reaching half a dozen plants. Then when the visitor has had his fill of specimens of foliage and flowering plants, he will find abundant amusement, accompanied by a good deal of instruction if he will, by inspecting the *Lælias*, *Cattleyas*, *Dendrobis*, *Oncidiums*, *Odontoglossums*, *Masdevallias*, *Lycastes*, *Cypripediums*, and such like, which merit greater detail concerning them, but time and space forbid.—J. H. E.

ECONOMIC ENTOMOLOGY.

[Presidential address to the Highbury Microscopical Society, by James A. Forster.]

(Continued from page 455.)

AN important element in the education of a farmer should be the teaching the use of the magnifying lens and the naturalist's habit of close and minute examination and accurate estimation of the facts he observes. Indeed, not only for the farmer is this teaching necessary, but I would urge that it, with a general teaching of zoology, ought to form a distinctive part of every boy's education. I mean that Natural History should not (as is now mostly the case where it is taught at all) be taught as an extra subject, but it should have a prominent place in the curriculum of every school, to be taught with as much regularity and earnestness as grammar or language. These, surely, cannot excel it as a means whereby to train the youthful intellect to habits of close, careful, and accurate reasoning, order, and patient attention. The study, properly directed, of God's creatures can hardly be of less value as a mental and moral training than that of a dead language, and must necessarily bear much more nearly on our daily life.

The insect kingdom—by far the most numerous in species of any corresponding group throughout animal life—is, as you are aware, classified into some twelve or thirteen principal families. Each of these families sends its quota to the host of the insect marauders of our gardens and fields. Happily for us, each group also contains not only species, but entire families, whose object in life is to prey upon these pests, to hunt them down, to devour them in each stage of their life. Thus has Nature put a check upon their increase, without which the human race would quickly have been eaten out of the land. Without these natural allies, we should have been powerless to overcome these deadly if minute enemies—the more deadly, indeed, because of their minute size, which renders it so difficult for us to discover them till the mischief they cause is well-nigh irremediable.

It is, then, evidently of the first importance that we should acquire that knowledge which shall enable us to recognise our friends so as not to confound them in the wholesale destruction we attempt to bring about of our pests. As a first step towards this knowledge, it is to be observed that the Insecta—like the higher animal kingdoms—comprises groups of vegetable-feeders and of flesh-feeders. Now, it is amongst the former that are found those insects that cause the most serious losses to our various crops; while it is to the latter—to the predaceous and carnivorous class—that we are indebted for the keeping within bounds the enormous increase of the devourers of our fruit and food that would otherwise take place by reason of the wonderful powers possessed by them of reproduction. It is thus, as in so many instances throughout life, that Nature provides, as it were, a natural balance of forces, and I would ask, What can we do more wisely than avail ourselves of Nature's own means of keeping in check the myriads of foes that would, if left to themselves, turn our fields and our gardens into barren wildernesses? Had our Hop-growers perceived the truth of this, and persistently and patiently fostered by every means in their power the settlement in their gardens, and the increase, of aphid-eating insects, such as the Lady-birds (*Coccinellidæ*), they would have largely mitigated, if not entirely prevented, the almost incalculable losses they have suffered from the so-called "black blights," which, instead, have become of increasing frequency during the past fifty years. The great loss caused by the ravages of aphides alone to Hop-planters and the whole community may be well brought home to us by the following facts and figures:—

In 1882 a serious blight occurred throughout the Hop-growing districts of England, causing a reduction of the average production from 7 cwts. per acre to less than 1½ cwt. Now, as in that year the Hop acreage was about 65,600 acres, the total yield of which was under 115,000 cwts. instead of 460,000 cwts., it follows that the loss on the crop was about 345,000 cwts., which, taken at the average price of Hops for the preceding twenty years (£7 7s. per cwt.), amounts to over £2,500,000 sterling loss in that year to the cultivators alone. But it was not they alone who directly suffered for it. It is estimated that not more than £150,000 was paid that season for the picking of the crop, while had it been an average one, the cost of picking would have amounted to nearly £400,000. So nearly a quarter of a million sterling was lost to the labourers in that one season. What an amount of misery is expressed in these figures!

A few facts concerning our Apple orchards may further serve to justify my claim for the economic importance of my subject. There are in England, according to recent agricultural statistics, at least 250,000 acres under fruit cultivation, of which by far the larger part is occupied by Apple orchards, forming a very important item in the crops of many districts in Devon, Somerset, Herefordshire, and Kent. Now, the Apple, amongst its many enemies, suffers from the attacks of two little moths and their caterpillars—the small Ermine moth (*Hyponomeuta padella*) and the Codlin moth (*Carpocapsa pomonella*). The former, in the years 1865 and 1887, entirely devastated whole orchards

throughout Kent and also the West of England. Hundreds of acres of orchards were to be seen in the month of July of those years without a leaf upon them—as bare, in fact, as though in midwinter. Every leaf, every bud, every blossom, had been cleared off by innumerable swarms of Ermine moth caterpillars, which had not only entirely destroyed the crop for the season, but had so seriously injured and weakened the trees that they produced but very small and poor crops in subsequent seasons. Again, in 1880, much damage was done by the same insect.

In 1877, the second of the above-named moths, the Codlin moth, caused much mischief to the orchards of Kent, where, it was estimated, about thirty per cent. of the Apples fell immature by reason of the maggot having penetrated to the core. And, further, it was found that a large portion of the fruit that did ripen would not keep from the same cause. As this moth specially attacks Pippins and the choicest descriptions of dessert Apples, the pecuniary loss to the growers must have been very large; but as there are no official statistics it is not possible to estimate the amount. In the cider-producing districts, the destruction of half the crop, which frequently takes place through the ravages of these two insects, must represent a very heavy loss to the farmers. Very frequently the above mischief is attributed to the weather, to the east wind, to that all-embracing word when used by the gardener, "Blight;" but if the observers would look closer and more accurately the true enemy might easily be discovered. When a gardener, seeing one of his trees with all the leaves shrivelled up, drawn together, and enveloped, as it were, in cobweb, with the blossoms falling off before mature or not opening at all, tells you in a mysterious manner that there is a "blight in the air" or that the tree is "struck," he is only confessing his ignorance and want of observation, and consequent inability of taking such precautions as shall render a recurrence of the misfortune unlikely or at any rate less severe.

The limits of this paper and my lack of knowledge alike render it impossible for me to attempt more than to describe a very few of our insect foes; but these that I shall now mention will serve as a sample of the rest, and the consideration of their life-histories will, to some extent, indicate the methods of observation necessary for their study. As I have already said, each of the great insect families contributes its quota to the devastating army. Certain families—notably, the beetles (*Coleoptera*), the bees, wasps, ants, &c. (*Hymenoptera*), the ephemeras, dragon-flies, &c. (*Neuroptera*)—send us friends as well as foes; others, like the aphides (*Homoptera*) are unmixed evils. The aphides, are perhaps, the most terrible and dangerous of all our scourges, and one of the most difficult to overcome, their amazing power of increase being unequalled throughout the animal kingdom. There is scarcely a plant that is not attacked by them, nor a locality where they are not to be found in numbers, and, under their popular name of "blight," dreaded by all gardeners and cultivators. At first sight it would hardly seem that they could be worthy of much attention. Their round, short bodies, nearly all belly, are carried on the frailest of legs; their habits are so sedentary that they seem intended to remain stationary; where they are born, for the most part, there they live and die, without giving any evidence of the instinct so frequently met with in insects. Their lives might almost be described as vegetable. Yet their organisation is most singular, and their fecundity in certain seasons so prodigious as to make them a real scourge. They infest every kind of tree, plant, or flower. The rarest flowers in our hothouses and the commonest flowers of the hedgerows alike serve them for home and food; in short, they are of all climates and all seasons.

They are both oviparous and viviparous. Their eggs, fixed to the plants by a viscid secretion, have the appearance of little, black, oval, shiny grains, deposited irregularly in large numbers on the sheltered side of branch or leaf. The young larva when extruded from the egg is nearly of its full size, and presents but little difference in appearance to the perfect insect. It emerges from the egg by a sort of trap or cover, and falls out backwards. Shortly after their birth, the young aphides work their way on to the tenderest and greenest part of the plant on which they find themselves. They crowd close together, their heads usually pointing to a common centre, and fix themselves by means of the large beak with which their mouth is furnished, and through which they incessantly suck up the sap of the plant, exhausting it and causing strange excrescences like galls, and in the end the plant becomes deformed and ruined. When three days old, the larva changes its skin; this is repeated three times at similar intervals. For the greater number, these metamorphoses produce but little change in appearance beyond a small tail, which develops at the end of the abdomen. When about nine days old, the female aphid (conditions of food and temperature being favourable) begin propagating their species by giving birth to living larvæ without having had any connection with the male. This has been described by Professor Owen as follows—

"This larva, if circumstances of food and warmth be favourable, will produce a brood—indeed, a succession of broods of larvæ—like itself without connection with the male. In fact, no winged males will have appeared. If the virgin progeny be also kept from any access to the male, each will again produce a brood of the same number of aphides, and carefully prosecuted experiments have shown that this procreation from a virgin mother will continue to the eleventh generation before the spermatic virtue of the ancestral coitus has been exhausted."

In favourable seasons, a certain portion of the third and fourth of these viviparous generations undergo special changes. At the first moulting small processes are observed on the back. These at successive moultings become largely developed, and after the fourth and last change of skin appear as large, fully formed, transparent wings, on

which the insect can fly away to fresh fields and pastures new. These winged aphides produced during the summer are always females. When two or three days old they take their flight to found new colonies. After the fourth generation, no further winged females are produced.

Towards the end of autumn the generations, usually eleven in number, approach their close, and the last brood produces a certain number of winged males, who fly off in search of partners. Reproduction then follows its normal course. The females, after marriage, give birth to no more living larvæ and produce only eggs. These remain during the winter protected by impervious shells from the cold, which would destroy the soft larvæ. In the spring these are hatched, producing larvæ as already described, who in their turn repeat the viviparous generations.

This is a brief outline of the life-history of the aphid family, which contains many species, many of them only too well known to most of us, like the Hop-fly (*Aphis humuli*). There are various species peculiar to certain fruits and plants. Indeed, each fruit seems to have its special aphid. Thus we have the Apple aphid (*A. mali*), the Plum aphid (*A. pruni*), the Currant aphid (*Rhopalosiphum ribis*), and many others. Mr. Whitehead writes of the Apple aphid:—

"The Apple aphid, or green fly (by which appellation it is better known), derives its food solely from the juice of the leaves and blossoms. It makes its appearance as soon as the buds begin to swell and the leaves show signs of coming forth, and it follows up the blossoms from their earliest development. The aphid attacks the blossoms, being specially attracted by their saccharine qualities, and either prevents the process of fructification or so besets the tiny fruits that, weakened by the extraction of their juices and begummed with viscous honeydew, they are unable to set properly. The fruit that perchance survives rarely attains to full size, shape, or quality. As the leaves come out, their under surfaces are occupied by the aphid, and soon curl up, get black, and fall off, leaving the trees bare, and emitting a sickly smell from all sides."—(*Journal of Microscopy*.)

(To be continued.)

FRUIT FORCING.

FIGS.—Earliest-forced Trees in Pots.—The trees in houses closed in November with fermenting materials in the pits will now or soon be showing growth by the swelling of the terminal buds. The roots also that were cut back will under the influence of genial heat be sending forth fresh feeders through the fresh compost placed about the pots. When this is the case the fermenting materials should be examined, and if the heat does not exceed 75° they may be trodden down round the pedestals and bases of the pots, preparatory to the introduction of a fresh supply from the reserve heap, which should be under a roof of some kind, as the heating and manurial value is soon lost by exposure to drenching rains. At any rate, all material used for bottom heat or plunging purposes must be properly worked and warmed before being taken in. Take care that the heat about the pots does not exceed 70° to 75°. The heat and moisture given off by the fermenting materials will greatly facilitate forcing operations by softening and reducing the amount of fire heat. On cold nights the temperature should fall to 50°, and 55° by artificial means in the daytime will be sufficient, with a rise of 10° from sun heat. Syringe the trees and walls with tepid water on fine mornings and again early in the afternoon, or about 2 P.M., but with the moisture arising from the fermenting materials there will rarely be need of more until the trees begin to push fresh foliage. Keep the glass clean and free from condensed moisture by ventilating on all favourable occasions.

Succession Houses.—If the pruning is still in arrears lose no time in getting the work finished. Cut back or entirely remove all old spurs, and thin out the least promising shoots that have reached the extremity of the trellis to make room for free growth and full development of wood and foliage. As the Fig delights in heat, moisture, and good living, with plenty of light and a free circulation of air, the house should be well heated, be light and well ventilated, and generous treatment accorded, otherwise it is the most insipid of fruits. Thorough cleanliness is necessary to success, therefore spare no pains in cleansing the trees, woodwork, and walls, and paint if necessary. If brown scale has been troublesome syringe with petrolcum at the rate of a wineglassful to three gallons of water, keeping it well mixed with the water whilst it is being applied. If applied with a brush it may be used much stronger, or at the rate of a wineglass to a gallon of water, at which strength it will destroy all insects it comes in contact with.

PEACHES AND NECTARINES.—Earliest House.—The blossom buds will now be swelling. The house having been closed at the middle of November the temperature should be slightly increased in the day time, especially when the weather is mild or marking 50° outside and a soft wind blowing. Turn on heat in the morning so as to raise the temperature to 55°, and allow a rather free circulation of air, and with sun the temperature may rise to 60° or 65°, the heat being turned off

at night to allow the temperature to fall to between 45° and 50°, and on cold nights it may fall 5° lower without any disadvantage. Avoid a dry atmosphere, especially from fire heat. Gently syringing the trees is of great benefit. If fermenting materials have been introduced give a little extra attention in turning and additions, which will impart activity to the surface roots. When the soil is at all dry give a good application of tepid water, or if the soil has left the walls, as it sometimes does, during the resting period, it should be well rammed down to make the water enter by the surface, otherwise it will run off.

Succession Houses.—Complete the pruning and cleansing in houses intended to be closed soon or at the new year. Lay in the wood sufficiently thin to admit of the full development of the foliage, as fine fruit of good colour and flavour cannot be obtained when the young wood and leaves are deprived of the benefit of light and air. Keep all doors and ventilators open in all but actual frost. Even this will not do any harm; but structures of this kind are often filled with plants, and in the anxiety to save these the lights are frequently closed when they should be open, and imperceptibly, but surely, the buds will swell, so that between alternate excitement and its opposite they receive a check, and if the trees do not cast the buds the flowers are weak and set very badly. It would be much better to remove the roof-lights altogether and keep them off until the time arrives for closing the house. No frost will injure the trees provided the wood is ripe.

CUCUMBERS.—Keep the night temperature steady at 60° to 65°, and the day at 70° to 75°, being very careful in the admission of air, though a little should be given to clear the glass of condensed moisture and admit all the light possible. It is hardly necessary to point to the desirability of preventing the temperature being unduly lowered by frequently opening the door in severe weather, which may be obviated by having the thermometer in such position that it can be seen from outside. A mat suspended over the door is also useful in preventing an influx of cold air when the door is opened. Remove all superfluous fruits from the plants immediately they show, and tie up all shoots to the trellis as they require it. Encourage vigorous growth, on which stopping should be moderately practised, otherwise very little stopping will be required. Should mildew appear, dust the affected leaves with flowers of sulphur and maintain a somewhat dry atmosphere. For red spider sponge with softsoapy water, and if green or black aphides attack the plants, dust with tobacco powder; or, if fumigation be resorted to, it must be done with great care and judgment.

Prepare some Oak or Beech leaves with a third of stable dung by throwing them into a heap and damping if necessary, turning them when they have become warmed through outside to inside, and watering if necessary, so as to secure an even and thorough fermentation of the materials, with which to make a hotbed at the end of this month or beginning of the new year to raise Cucumber and Melon plants from seed, and subsequently to make beds for planting them in.

THE FLOWER GARDEN.

Own-root Roses.—Readers of the *Journal of Horticulture* will have learnt that to be successful with dwarf Roses these must either be on the Briar stock or on their own roots. The latter are preferable in many instances as being the least trouble to raise, and those who have a good stock of healthy bushes, standard or wall trees, ought to be able to take off many dozens or even hundreds of cuttings without injuring their plants in any way. There are a few varieties that fail, notably those with many thorns, but as a rule the majority will, if the work is properly done, strike readily and form good flowering plants during the following summer. The cuttings ought to be put in at once, and the first proceeding should be to prepare the ground, as the sooner the cuttings are inserted after they are made the greater the probability of their striking. If they are once allowed to become dry or shrivel in the least, failure to strike is almost certain. Preference should be given to a good open piece of ground, and the top spit should have a liberal addition of old Mushroom bed manure or leaf soil, and either road grit or sharp sand. This ought not to be buried with the spade, but should be well mixed with the surface soil with the aid of digging forks. This should be done only a short time before the cuttings are ready, as it is of importance that these are inserted before the newly moved ground has become saturated by rains. It is the long well ripened growths that are most suitable for making into cuttings. They should be cut into 1-foot lengths, the lower half being cleared of thorns and buds, and the base cleanly cut to a joint. Each variety ought to be kept separate and labelled. When a good number have been prepared, first trample or firm the ground somewhat, and then cut out a narrow trench, as if for laying Box edging, and about 6 inches deep. Set the cuttings from 6 to 9 inches apart in this, taking care that all are pressed against the bottom, return the soil, and well fix it against the cuttings with the foot. Another trench may then be cut with the spade from 12 to 15 inches from the first, and in this way a good breadth of ground may quickly be covered with Rose cuttings.

Last winter fully one-half the cuttings inserted failed to strike, owing to the ground being frequently upheaved by frosts, looseness of the soil about them being fatal to a good strike. In order to obviate this difficulty spread not less than two inches of fine coal ashes or cocoanut fibre over the surface, and if this does not quite prevent upheaval, firm the ground with the feet as often as the cuttings are found to be loosened. The more vigorous of the Teas and Noisettes may be struck in this manner, these including Maréchal Niel, Gloire de Dijon, Madame Berard, Catherine Mermet, Souvenir de Paul Neron, Safrano, Homère, Madame Lambard, Céline Forestier, Adau, and Souvenir d'un Ami.

The very useful Bourbon Souvenir de la Malmaison strikes readily, and so also does Baron Gonella, Cheshunt Hybrid, and La France, which also might safely be classed with the Hybrid Teas, rarely fail to strike, and are among the best that can be grown. All the Hybrid Perpetuals should be tried, but it is useless to attempt striking cuttings of Moss Roses.

Ordering Roses.—In many districts it is advisable to commence planting Roses at once, and in any case no time should be lost in ordering what are required from the nurseries. If they cannot be planted directly they are received they will not be injured if kept laid in thickly by their heels—that is to say, with their roots covered with fine soil, till they can be properly planted. Where dwarf or other Roses are liable to be killed to the ground or to the snow line by extra severe frosts the bushes ought to be ordered, and when received be laid in closely till early next spring. Being kept well together they can readily be protected when necessary by either straw litter or bracken, and will form many root fibres before they are disturbed again.

SELECTIONS.—Hybrid Perpetuals.—The following may be grown for all purposes, either on dwarf or tall Briar stocks, or on their own roots—Abel Carrière, Alfred Colomb, A. K. Williams, Baronne de Rothschild, Beauty of Waltham, Boule de Nîge, Captain Christy, Charles Darwin, Charles Lefebvre, Countess of Oxford, Countess of Rosebery, Dr. Andry, Duke of Wellington, Duchess of Connaught, Duke of Edinburgh, Edouard Morren, Emily Laxton, Empereur de Maroc, François Michelin, Général Jacqueminot, Her Majesty, John Bright, John Hopper, La France, Madame Gabriel Luizet, Madame Prosper Laugier, Madame Thérèse Levet, Mdlle. Eugénie Verdier, Mdlle. Marie Raly, Marie Baumann, Maurice Bernardin, Merveille de Lyon, E. Y. Teas, Prince Camille de Rohan, Sénateur Vaisse, Ulrich Brunner, Violet Bouyer, and Xavier Olibo. The foregoing is a rather long selection, but it does not exhaust the list of varieties worth growing.

Bourbon Roses.—Of these the best are Acidalie, which succeeds admirably against walls; Baron Gonella, Queen of the Bourbons, and Souvenir de la Malmaison. All are suitable for planting against walls or in the open, and Queen of the Bedders, one of the most floriferous Roses in cultivation, Garden Favourite and Malmaison Rouge are also worthy of a trial.

Tea-scented and Noisettes.—As a rule the majority of these succeed best against sunny walls and fences, but many of them do well either as dwarfs or standards in the open. Even the old Gloire de Dijon and Maréchal Niel frequently form fine floriferous heads on tall Briar stocks. Some of the best of the Teas are Alba Rosea, Anna Ollivier, Catherine Mermet, Climbing Devonensis, Duchess of Edinburgh, Etoile de Lyon, Gloire de Dijon, Grace Darling, Isabella Sprunt, Madame Berard (good for walls), Madame Falcot, Madame de Watteville, Marie Van Houtte, Niphotos, President, Reine Marie Henriette (for walls), Souvenir de Paul Neron, Souvenir d'un Ami, Souvenir d'Elise, The Bride, Sunset, Adam, Comtesse de Nadaillac, and Rubens, the three last named being the least hardy in the selection. Of the Noisettes Céline Forestier will do well either as a standard or against a sunny wall, and Jaune Desprez, Madame Caroline Kuster, Maréchal Niel, and Rêve d'Or, Triomphe de Rennes, and William Allen Richardson all quickly cover walls or pillars, and as a rule are very floriferous.

OTHER ROSES.—*Moss Roses* succeed either as dwarfs or standards, and the most reliable are Baronne de Wassencar, Captain Ingram, Common, Comtesse Murinais, Lanei, Reine Blanche, and White Bath. The foregoing are summer flowering only, and those of a perpetual character worth growing are Eugénie Verdier, Blanche Moreau, Perpetual White, Souper et Notting, and Salet. The *Hybrid China* and *Hybrid Bourbon* Roses are all suitable for covering pillars either against dwelling houses or in the shrubberies. Some of the best are Blairi No. 2, Brennus, Charles Lawson, Coupe d'Hébe, Paul Perras, Paul Ricaut, and Vivid. The white and red varieties of *Rosa rugosa* are very effective in the front of shrubberies, and these may either be grown as half-standards or as bushes. *Single Roses* are becoming very popular. A selection of these ought to include the copper and yellow Austrian Briars, the Persian Yellow, Paul's Crimson, and White Perpetual, Polyantha, and Macartney Simplex. The old *China Roses* are also still worthy of culture, notably Cramoisie Supérieure, Mrs. Bosanquet, Old Plush, and Old Crimson. The white and yellow *Banksian Roses* are suitable for planting against the sunny fronts of houses and for covering pillars. They are evergreen and beautiful when in flower. For north or cold walls such strong climbing Roses as Amadis, Dundee Rambler, Felicité Perpetuelle, and Rampant are suitable. The *Miniature* or *Fairy Roses* are best adapted for pot culture, but Lawrenceana rubra, White Fairy, and Alba will succeed in the front rows of Rose borders.

KITCHEN GARDEN.

FORCING ASPARAGUS.—We cut our first dish of this favourite vegetable on November the 24th. The produce was ready for cutting in twelve days after the roots were placed in the forcing quarters. It is an easy matter to secure plenty of Asparagus in winter where the crowns are well developed and abundant, but these two conditions are absolutely necessary. Roots that have been well grown for four or five years force freely, but a hotbed and frame are not the best appliances to use in forcing at this season nor until the spring. Our forcing place is not very elaborate; it is a low pit with a bed in front, a stage at the back and a pathway in the middle, heat being supplied by a flue which goes under the bed in front but is exposed along the back, the former giving the bottom heat and the latter the surface warmth, and it is here we are

now cutting Asparagus. The roots are lifted without breakage and packed as close as they will stand in the bed with a little soil under them and as much over them as will cover the crowns. Water to make the soil moist, keep it in this condition and the bottom heat ranges from 75° to 85°. For maintaining a supply place in more roots as soon as the heads from the preceding are ready for cutting. It is fully exposed to the light from the first and grows as if it was in the open air.

THE MUSHROOM SUPPLY.—If good Mushrooms can be gathered daily or every other day, they will scarcely fail to meet with acceptance in the kitchen and on the table. A large bed formed in a potting shed in October is now producing multitudes, and will continue bearing until after Christmas, as the heat in it now is 79°, not 10° less than when it was spawned, and so long as this can be maintained Mushrooms will be produced. For retaining heat the beds should be about 18 inches in depth, and very firm. In making up new beds let the manure be moderately dry, turn it frequently to allow the surplus moisture to escape, then press the material into a firm mass.

KIDNEY BEANS.—Of late we have had much rain and little sunshine, damp and dullness predominating, and these are conditions not favourable to the success of Kidney Beans in pots, and to secure pods throughout December the temperature must be kept at 75° or 80°, not less than the former, and the plants should be kept moist at the roots, but a damp atmosphere must be avoided. Sow seed to produce plants that will bear about the end of January.

FORCING SEAKALE.—Seakale does not force so freely as Asparagus. It requires upwards of four weeks to be ready by Christmas. Select the strongest crowns to force thus early, planting a number of them in a 10-inch or 12-inch pot. Eighteen or a dozen pots will give a good supply. A hotbed made in the Mushroom house or a dark shed will be suitable for plunging the pots in up to the rim. Pots may also be placed on hot pipes or a flue, but the growth must be made in total darkness, as green Seakale is not good. If placed in any warm place with the pots exposed, much water will be required, but when plunged very little suffices. The time has not arrived when the crowns can be forced with advantage in the ground.

FORCING CHICORY.—Forced Chicory is one of the most valuable winter salad plants we possess; the roots are Carrot-like in form, and if dug up, potted, and plunged with the Seakale they will soon produce a large quantity of creamy, crisp leaves that will be much relished as salad. Cold frames containing Lettuce, Endive, Cauliflowers, &c., are now very damp, and should be ventilated freely on every favourable opportunity.

PLANT HOUSES.

Adiantum cuneatum.—When the whole of the fronds that are suitable for cutting have been removed from these plants place them in a temperature of 50°, and keep the soil rather dry side at their roots. Do not place them in a lower temperature, or they will fail to start freely into growth afterwards. They will rest under the conditions advised and be ready for a good start again early in January. Do not keep plants still growing in a temperature above 55°, and admit air when the weather is favourable. Fronds from plants grown on this principle will last double the time in a cut state, as would be the case if they were grown in a warm confined atmosphere. Keep young plants in 60's steadily advancing, so that they will be ready in a month or six weeks for placing into 5-inch pots. These will yield useful plants for decoration or cutting by April.

Scented Pelargoniums.—Where the foliage of these are appreciated in a cut state watch carefully for aphides, for they are very liable to attack these plants at this season of the year. If the plants are subjected even to light fumigation with tobacco the foliage will turn yellow. The best means of eradicating aphides without injury to the plants is to dip the parts affected directly the insects are seen in a weak solution of tobacco water. Avoid cutting out the tops of a number of plants, for they will continue growing in a temperature of 55°, and will yield suitable leaves in succession for use in small vases. Keep plants from which all the growth has been removed rather dry.

Cypripedium insigne.—While this plant is doing duty in the conservatory be careful not to give too much water. Do not stand the plants in draughts or crowd them. To show the flowers to advantage let the plants be slightly elevated above surrounding objects.

Bougardias.—As these cease flowering keep them on the soil with their roots rather dry to induce complete rest. Many are lost after flowering by being kept too wet. The object now is to rest thoroughly those that have done service, so that they will be ready for starting early to yield strong robust cuttings for next year's stock.

Zonal Pelargoniums.—Where these are employed in conservatories many will cease flowering during the present month. Select the best shaped free-flowering varieties, and place them on a shelf close to the glass where they can be kept in good condition for the present without growing. With gentle heat after the turn of the year these will soon flower again. Plants not required for this purpose may be kept dry at their roots until the middle of January, when they can safely be pruned and started again into growth. Water plants in flower with care, and keep the atmosphere of the house dry. Weak stimulants may be given every time water is needed.

Heliotropes.—To keep these flowering freely they must have a temperature of 60°. Plants that have been employed up to the present in a temperature 10° or 15° lower will show signs of discontinuing growth. If these are removed at once to the temperature advised above they will soon grow and flower freely again.

THE BEE-KEEPER.

WINTERING BEES.

As no one year is sufficient as a test for the safe wintering of bees, it will be well for bee-keepers to keep a sharp eye on their hives, so as to be able to detect any dead bees, and to discover the cause. Damp is the worst enemy bees have to contend against during inclement weather. When a floor is damp many bees perish on it, and in any case damp causes a coldness detrimental to the bees. Frequently we hear of clusters of detached bees being found in the hive, as well as the floor being covered with dead bees. I never had a case of either in my apiary, but I may perhaps be able to point out a few of the causes.

A projecting alighting board catches damp, and if it form a piece of the floor the damp is drawn inwards and the bees and combs, as well as the honey, suffer. Impervious coverings either next the bees or close on the top of other material on the hives also causes damp through condensed moisture. Too much doorway when the atmosphere is damp with a low temperature is also unfavourable. Bees located in a hive that is broader than high suffer when a low temperature occurs, and detached clusters of bees die. Double-cased hives that are dovetailed contract damp readily, more so than those nailed with a close-fitting joint. Wood or other material that absorbs damp next to the bees is worse for them than when a non-porous material is used. Wooden hives are better oiled, painted, or tarred on the inside, than left so as to absorb damp, provided a ventilating floor is employed, and with a doorway not more than an inch wide and in a narrow hive bees will winter well and come out in the spring in good health, no matter what the winter has been. The "Long Idea" or other lateral hives on the broad principle contract damp much more readily than the narrow type of hive. The honey from them, too, during summer is always more watery than the honey stored above the bees is in a narrow hive, while in winter it is both colder and more watery and causes disease amongst the bees, while those in a narrow hive are healthy.

The best way to protect hives from rain and inclemency of the season is to have the sides, and particularly the top of the hive, well covered with dry meadow hay and surmounted with a projecting rain-proof roof, elevated a little, so that it acts as an umbrella does, allowing the air to pass around and over the hive without the possibility of rain entering or touching the hive anywhere, and always have the alighting board detached or moveable, so that it will not conduct water to the interior. The proper quantity of hay to employ is just as much as when pressed by the hand it will feel soft and the perceptibility of the wood absent. Bees cannot have a too ready entrance to their combs. Those having a court between the outer and inner wall is the cause of the death of many bees, as well as intercepting the air before it reaches the outer world. Such hives necessitate close watching and a hooked wire to draw out the dead bees. Hives having their combs right to the doorway may be termed safe, as the bees when "airing" come to the entrance in a body, keeping the combs and entrance warm, so that bees returning almost exhausted (as they often are in winter), when they reach the entrance and catch hold of the combs are safe.

The foregoing are some of the features the bee-keeper should become acquainted with, and when the wintering of bees is mastered, the management during summer becomes more simple, ending in success. For two weeks now my bees have kept constantly within the hives. Last year at the present date some of the Syrians had a number of dead thrown out, and had been prisoners for two months this year. No dead bees are around yet, and should seasonable weather continue for another three weeks breeding will be commenced. On the 9th of January, 1888, one of the finest days during the year, the bees began work and continued until dusk the same day, and wrought more or less up till the 18th November. Never, in all my experience, have queens been

taxed to such an extent as in the present year. The bee-keeper should turn his attention to all stocks having 1887 queens, for assuredly there is a likelihood of many of them being deposed before swarming time.—A LANARKSHIRE BEE-KEEPER.

THE "HALLAMSHIRE" GLASS SECTIONS.

"A SUSSEX AMATEUR," page 458, wants to know how the above can be fitted together and placed in the racks ready for use in less time than the present wood sections, and he would like me to supply the 4000 pieces of glass for 10s. To explain the first will require some drawings and several columns of letter-press; in fact the glass sections are only part of a new system that bears about the same relation to the present bar-frame principle that the latter does to the skep. If your correspondent will refer to the Journal for November 1st, he will see I have promised to publish full particulars, but I do not consider it wise to do so just yet when everyone is sceptical about the plan. When a goodly number have realised that they can be done, and are willing to learn the process, then will be the time to instruct them. Before this can happen we must break down the opinion that "the idea of glass for sections is absurd—a thing as impossible as perpetual motion." This brings me to notice a leading article in a contemporary for November 1st. I sent a reply to it which dealt with every one of his objections against glass, but it was not published. You, Mr. Editor, who have seen the whole case, can testify that it was a fair sample, and not the best one either, therefore I feel constrained to deal with the objections here.

The first objection is the difficulty of procuring sheets of glass of equal thickness. This does not apply to my sections, as no matter how many different thicknesses of glass there may be, all are cut with the same tools, and yet the outside measurement of the sections will be exactly alike, all variations being thrown inside, where, of course, it does not matter.

The second is the cost, in comparison with the American one-piece. He says suitable glass costs not less than 3d. per square foot, and at this rate a thousand sections will cost in glass alone £4 3s. 4d. The writer does not clearly show how he works out this little sum, so I cannot test his arithmetic, which may be as sound as the idea of going to buy glass by odd square feet to make 1000 sections. Here is my answer to this, which all can test for themselves. My sections are $5\frac{1}{4}$ inches high by $3\frac{1}{4}$ inches wide, by one-nine-sixteenth inch thick. This size holds 16 ozs. of honey without the glass. A piece of glass $33\frac{1}{4}$ inches by $42\frac{1}{4}$ inches—under 10 square feet—will make fifty-four sections. A "case" of 15-oz. glass contains 300 square feet. This will cut up into 1620 sections at least; it will make a few more with a little care.

These cases can be bought for 24s. to 26s. per case; or box glass for 9s. to 10s. 6d. per box of 100 feet. These latter are cut for ordinary window panes, so that sizes can be selected that will cut up without any waste; thus it will be seen that if we have to use new glass it will not cost more than 15s. per 1000, and a pair of hands could easily cut up 50,000 per day, so I do not see that the price would exceed that of the American wooden ones. But I do not propose to use new glass at all, as in every glass warehouse throughout the country there is a vast quantity of waste glass made, consisting of long narrow strips, which are thrown under the bench with a twist to smash them as small as possible. For this glass, called "cullet," they get from 15s. to 20s. per ton. Every piece three-one-eighths by one-nine-sixteenths, of which will make a section side, and I find they will readily put all these strips in boxes for me for 2s. 6d. per cwt. Though 1 cwt. will not make quite 1000 one-pound sections, 2 cwt. will make 1000 each one and two pound. As I think more of this cullet will always be produced than will ever be required for sections, I think I am well within the mark in saying that my sections do not cost in glass more than the odd 3s. 4d. named in the estimate already mentioned.

The third objection is expressed by asking, "What bee-keeper can afford to add a card or other fancy case to comb honey worked in such an expensive (?) receptacle?" My answer is, that glass sections require no "card or other fancy case;" they are insect and dust proof, nor could anything be added without spoiling their beauty. Therefore, by using glass sections the expense of a "fancy case" is saved.

In the fourth he objects to "four unattached pieces of glass" as not being safe to handle. Well, the fact that the first one safely reached the Editor's hands through the mail; that another I have carried in my coat pocket for about 500 miles, and shown it to about 100 different people, should be proof sufficient that such fears are groundless.

In his fifth he says the wax comb will leave the glass and the honey run out, making the section unsaleable. This, as a matter of fact, never can happen, and if the glass is too cold or damp the bees cannot "weld" their wax to it, and in trying to do so work their combs against the glass with a thick "frosted" appearance. When this is so they never put honey in the cells next the glass, as instinct teaches them it would run out. When the glass is kept warm and dry they work their cell walls on it almost as thin as paper; these being perfectly welded to the glass are invariably filled with honey. In connection with this there is a most important point to consider. It is well known that the combs in wooden sections crack in cold weather, setting the honey bleeding; this is caused through the honeycomb contracting within the wooden section, which will not expand or contract with heat and cold. Glass has this property; in fact it contracts and expands almost in the same ratio that honeycomb does. Hence with glass there is no fear of cracked or bleeding

sections. I have some glass sections now that have been worked two years; they have been frozen down to 20° and heated up to 90°, which show no crack and the honey is still clear.

In his sixth he says, "We have yet to mention one other serious drawback, common to all glass sections, and that is, the bees are not so willing to enter the super as where only wood is present." Whether this has been a drawback or not with previous attempts to make glass sections I will leave for others to discuss; what concerns me is the assertion that it applies to "all glass sections," including, by implication, all future ones as well. Now all bee-keepers who have worked the American sections know that bees do not readily take to them, and all kinds of dodging are resorted to to get them up. In my glass sections there is not this difficulty. If the bees are ready for supering they go up with a rush in a few minutes after putting on; they will also go up when they are not strong enough to remain in at night; in fact they take to them as readily as empty combs in ordinary frames.

Having answered all the objections, I beg to inform "A Sussex Amateur" that what I promised in the second paragraph of my letter on page 413 I intend to fulfil. I do not intend to sell the sections ready cut myself. I may supply the cutting tool at 1s. My object is to show every bee-keeper how he can make his own sections in winter, which is a time of the year he is little occupied with the bees. Cutting these sections will find him work and help keep up his interest in honey and bees. Some of these people will get very expert in cutting them. They may also be able to obtain a large supply of cullet at a cheap rate, therefore it is not out of the way to suppose numbers will be glad to sell them at 10s. per thousand. If "A Sussex Amateur" does not care to make his own—and what amateur would buy what he can possibly make?—he must look to these people for his supply.—A HALLAMSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Putz & Roes, Erfurt, Prussia.—*Annual Seed List, 1893-1894.*
S. F. Armitage, Nottingham.—*Catalogue of Fruit Trees, &c.*
Dickson & Co., 1, Waterloo Place, Edinburgh.—*Catalogues of Fruit Trees and Roses.*

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Exhibiting (Fair Play).—There are four classes on the cutting sent, and you do not state to which you refer. If to the plant classes, we do not think a gentleman employing a groom and gardener regularly would be eligible to compete.

Chrysanthemums for Exhibition (W. W.).—If you cannot select the leading varieties from the prize stands published in the reports of shows they will be tabulated in due time, and you can then choose the number required.

Chrysanthemum Sport (T. S.).—The flowers you send are those of Pink Christine, a well known reflexed variety. Mrs. Forsyth is White Christine, several other forms being also grown, as the Christine type has been found to be very variable and sportive.

Books (J. H. W.).—We should think that "The Elements of Entomology," by W. S. Dallas, published by C. Griffin & Co., Exeter Street, Strand, London, and Kirby's "Text Book of Entomology," published by Murray, Albermarle Street, London, would suit you. With respect to the other question, write to Mr. J. Browning, 63, Strand, London, for a price list.

Peach Trees Infested with Scale (W. W. Kent).—Syringe the trees with a solution of softsoap (6 ozs.) and soda (1 oz.) in 4 gallons water, adding a wineglassful of petroleum, keeping them well mixed either by alternate discharges from the syringe into the watering pot, or a second person stirring briskly with a broomhandle whilst the trees are being syringed. Repeat, if necessary, in the course of a week, and again before the buds begin swelling.

Marsh Mallow or Marigold (A. B. C.).—The Marsh Mallow is

Althaea officinalis, not an especially attractive plant, but we should think you mean the Marsh Marigold, *Caltha palustris*, which has showy golden flowers, and it would succeed admirably in such a position as that you describe. They require moist rich soil, and if favourably suited in this respect they will grow vigorously and flower freely in early spring. There are both single and double varieties, which you can obtain from any dealer in hardy plants.

Plants for Rockery (W. R. T.).—Do not confine your plants to those of a "creeping character," but mingle with them others of a dwarf, compact, or spreading growth, and the effect will be much more satisfactory. Among those which we find to answer are *Erica carnea*, *Azalea amœna*, *Kalmia nana*, *Erica Foxii*, *Phlox frondosa*, *P. Nelsoni*, *P. verna*, *P. setacea*, *Plumbago Larpetæ*, *Thymus lanuginosus*, *Silene maritima*, *Hypericum patulum*, *Lithospermum prostratum*, *Rhododendron ferrugineum*, *Andromeda floribunda*, *A. Catesbœi*, and *Gaultheria procumbens*.

Asphalt Walks (Young Hand).—Perhaps it is best made of two parts lime rubbish and one part coal ashes, both very dry and sifted fine. Mix and leave a hole in the centre of the heap, and into this pour boiling coal tar, mixing well together. When of the consistency of mortar spread it 3 inches thick, on a dry and previously well prepared or levelled surface. Sprinkle with sharp dry sand. When sufficiently stiffened pass a roller over the asphalt. A good foundation should be formed of rough material, and drains to carry off the surface water. The work should be done in dry hot weather. The ashes from engine furnaces will be the most suitable.

Heating a Peach House (Idem).—A flow and return 4-inch pipe will give sufficient heat in the Peach house, and you will need valves on both the flow and return so as to regulate the heat to a nicety, as the pipes being 3 feet higher than in the other houses, the hot-water circulation will be much freer. Either you must have the expansion pipe correspondingly higher or put in syphons, doing away with the open expansion pipe, and have a feed cistern in stokehole, allowing for expansion in fixing the Peach house pipes or have an expansion cistern. We should take the pipes across the yard as you propose, employing 2-inch pipes both for the flow and return. You will need air taps at the highest point of the pipes in all the structures.

Asparagus (A. A. B.).—If you dig up and divide the roots, re-planting a portion on the same ground and the surplus on land adjoining, you will gain time in the production of heads on the second plot, but lose in the case of the former through the check resulting from removal, this being small or the reverse according to the weather. Taking all things into consideration, we should not disturb the yearlings, but let them grow. Two or three plants together, a foot or 18 inches apart, in rows 2 feet asunder, will have no appreciable effect on the produce. Possibly you will be able to cut a greater number of good saleable heads from them sooner than you would from single plants, though these in time would perhaps afford some stronger growths. We usually sow two good seeds at the desired intervals, and are not greatly disappointed if both produce plants. If your soil is suitable for Asparagus the crop ought to pay very well, as you have facilities of disposing of the produce. If you want thick white stalks and green or purple tips only, they are obtained by piling earth over the crowns when the plants are strong enough for cutting.

Plants for Rockery (G. T.).—It is difficult to name plants that rabbits will not eat, as much depends upon their number, the severity of the weather, and the scarcity of their natural food—i.e., grasses and other herbage. The following are not usually eaten by rabbits, and will grow in rather shady situations, but not under the drip of trees:—*Arabis albida*, *Aubrietia græca*, *Azalea amœna*, *A. procumbens* (the two last are dwarf shrubs requiring heat), *Campanula garganica*, *Cistus* vars. but they are not very hardy; *Cotoneaster rupestris* (dwarf shrub) *Cyclamens Atkinsi*, *Coum. vernum*, *hederæfolium*, and *neapolitanum* do well in shade at the foot of rockwork; *Cytisus decumbens*, *Daphne Fioniana*, *Erica carnea*, *Genista præcox*, *Geum montanum*, *Iberis corææfolia*, *Lithospermum prostratum*, *Phlox Nelsoni*, *P. verna*; *Primulas* in variety do well at the foot of rockwork in partial shade; *Rhododendron hirsutum*, *Rosa rugosa*, and var. *alba*, *Saxifraga Camposi*, *Sedum spectabile*, and *Sempervivum arachnoideum*. The *Vincas* and *Hypericum calycinum* form a dense covering in shade, and rabbits care nothing about them. *Hellebores*, *Trollius*, *Trillium*, &c., do well in partial shade, and are fine at the foot of rockwork, where they have plenty of good soil and moisture.

Planting Peach Trees (S. T.).—We have never seen better Peaches than from trees grown in a border 15 inches deep resting on a gravel subsoil; but the border was composed mainly of good turfy loam of medium texture, and was mulched liberally with manure. You say you have some doubt as to whether your soil is suitable for Peach trees, yet omit to say one word as to its nature. All we can do, therefore, is to advise you to mix lime rubbish and gritty matter with it if it is heavy, and strong loam or clay dried and crushed if it is light. The trees may be planted at once, and a good covering of manure placed over the roots. You do not state the number you require. The following are good varieties for succession, and will ripen in a house without fire heat:—*Alexander*, *Hales' Early*, *Rivers' Early*, *York*, *Gros Mignonne*, *Royal George*, *Bellegarde*, and *Barrington*. These will probably be as many as you require. If you desire to plant a *Nectarine* or two, *Lord Napier* (early) and *Pine Apple* (late) will probably give satisfaction. If you can make the border 6 inches deeper by adding fresh loam, or such soil as would grow

first-class Potatoes, you will not err by doing so. You must be careful, too, not to keep the house too close in winter, or the blossom will expand too soon, and be cut off by spring frosts, notwithstanding the protection of the glass. We have seen many failures in unheated Peach houses, and we always think a well-built house incomplete where no provision is made for heating.

Defective Chrysanthemum Blooms (*Nil Desperandum*).—The so called sport from Duchess of Albany is only a deeply coloured bloom of that variety, which is deeply shaded with red and much superior to the many washy coloured blooms seen of this variety. The depth of colour contained in your bloom may have been occasioned by the nature of the soil or other conditions, such as bud formation, which alters considerably the colour of the blooms, which in some instances renders them almost unrecognisable. The late formed buds generally produce the deepest coloured flowers. The pink incurved bloom is Alfred Salter, which is lilac pink when in proper character. Empress Eugénie is rosy lilac, much smaller than Alfred Salter, the florets curl more, the foliage being quite distinct, much broader, and more fringed around the edge. The colour of the leaves is generally paler than those of Alfred Salter, which is an exact counterpart of Queen of England, from which it is a sport. The malformed blooms you send and the others which your name are caused by defective growth, which is a very common occurrence this season. The chief cause is the unfavourable weather experienced, another the immature state of the wood. Possibly the evil was increased by applying stimulants to the roots too freely, causing the growth to be too gross, which usually results in deformed flowers. Although many good blooms of Bronze Queen have been seen this season, large numbers have been defective in form, showing much more of a reflexed character than an incurved one. The wet, cold, sunless weather experienced has been all against well-formed solid blooms in the incurved section.

Tomatoes and Roses (*S. S.*).—No doubt very good crops of Tomatoes could be obtained from your house, at least the thinly-trained Roses on the roof would be no great impediment. It is not a question of the Roses interfering with the Tomatoes, but the Tomatoes with the Roses, assuming the roots of the latter are inside the house. If outside—and they are as well there—there will be no conflict. If you refer to page 361, the issue of October 18th, you will find an example of Tomato growing to follow. The plants there figured, and which are still bearing, have produced nearly £100 worth of fruit. They were planted 2 feet 4 inches apart during the first week in May, in a foot of good but not rich loam. The plants were 18 inches high or thereabouts when planted, with stems as thick as your thumb and flower buds visible. Such plants may be raised from seed sown very thinly early in March, the seedlings being placed separately in small pots, grown steadily and sturdily in a very light position near the glass, eventually shifting them into 5-inch pots, and growing them under the full influence of light, with as much air as they will endure for ensuring firm growth. When flowers are produced freely, a dry atmosphere should be maintained till many fruits are set, and not till good crops are swelling freely should very much water be given or stimulants used. Forcing the growth early, rendering it essentially soft in character, invites the disease that injures or ruins the plants. Perfection is the most profitable variety at Chiswick, as its large fruits have been in demand, but in many if not most markets fruits of medium size are preferred. Sutton's Earliest of All is useful for first gatherings, and you might try a dozen or more plants of it. Perfection, Gilbert's Surpasse, Hackwood Park, Excelsior, and its robust ally Ham Green Favourite, we have seen producing profitable crops this year. Horsford's Prelude is a splendid cropper, but the fruits are rather small, and might be too small in the hands of some growers. Those at Chiswick were perhaps as large as could be grown, and were sold for 1d. a pound less than the larger sorts, but the greater abundance of Prelude would render the value of the crop of the same number of plants of each not far below any of them. An enlarged form of the variety last named combining its productiveness would be a great acquisition. No artificial heat was employed in the Chiswick Tomato house after planting until the autumn for ripening late fruits. The plants were not topped nor laterals permitted to grow from the main stems. Blenheim Orange and Golden Queen are good yellow fruited sorts, if a few yellow fruits are wanted.

Returning Packages (*J. L. R.*).—Specimens sent to be named, whether of plants or fruit, are not returned, and it is understood that duplicates are kept by the owners of such that it is desired to preserve. It is impossible we can undertake to return specimens of the nature indicated.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*T. H. Slade*).—1, Cassante de Mars; 2, Doyenné Boussoeh; 3, Colmar d'Aremberg.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*M. G. M.*).—Flowers packed in tissue paper and dry wooden boxes

invariably arrive in a much shrivelled condition, and that was the state in which yours reached us. As nearly as we can judge, however, your plants are as follows, reserving two (Nos. 4 and 5) for further examination and comparison:—1, *Coccyne fuliginosa*; 2, *Maxillaria picta*; 3, *Oncidium Papilio*; 6, *Phalenopsis amabilis*. (*Northerner*).—1, *Cuphea emicans*; 2, *Lonicera sempervirens*. (*W. R. S.*).—1, *Sclaginella Martensi*; 2, *S. Kraussiana*; 3, *S. serpens*. (*N. M. O.*).—1, *Luculia gratissima*; 2, A variety of the above named *glabra* having smooth flower and leafstalks and stems.

COVENT GARDEN MARKET.—DECEMBER 5TH.

MARKET well supplied, prices remaining unaltered with the exception of Grapes, which are firmer, and Nova Scotia Apples, which are 2s. per barrel lower.

SHEEP MANAGEMENT.

HIGHLY desirable as the development of early maturity undoubtedly is, it has its limit of utility in practice, and we shall do well now to turn our attention to the requirements of the land from sheep. In the great corn-growing district of East Anglia corn and sheep farming have become blended so intimately that the one has come to be regarded as inseparable from the other. Under the agricultural depression many a farmer has been driven by stress of circumstances to sell his flock. Serious as have been all the attendant evils of hard times, there is not one of them

which we deplore more than this lamentable sale of all the sheep from a farm, for it is a sure sign and token of despair, failure, bankruptcy. To our postulate, "If the elements of fertility withdrawn from the land by a crop are restored to it regularly before taking another crop, exhaustion is impossible," all farmers will agree, whether they be advocates of muck or any other form of manure, and there is a consensus of opinion that there is no more certain or economical method of applying manure to land than by sheep. It is, however, by no means so certain that the full value of sheep folding is so fully recognised, yet the matter is so simple, that a grain or two of common sense, combined with an ordinary amount of intelligence, ought to convince anyone of its importance.

Folding really means concentration and thoroughness, and we do it, not so much for the clearance of a crop, as for the thorough manuring of the land. Confined within a fold for a given period of time, the sheep must do much more good to the land than if left to ramble at will over fifty or a hundred acres. By folding, we feed the sheep, and at the same time store the soil with fertility. The sheep should eventually make us a fair return for the crops they consume, and their manure not only saves an outlay for chemical manures, but it renders the next crop a full and profitable one. Clear, simple, and unmistakeable as these facts are, they form a primary rule for our guidance in sheep management. We must have sheepfolds going as long as we can throughout the year. As we sit writing this article we have two flocks of hoggets on the road; one flock being driven some fifteen miles to be folded on Turnips, with crushed corn and chaff, the other some twenty miles for the same purpose. The last flock of three hundred hoggets has been kept on a heavy land farm till the Turnip folding was done, our object being to get through with this before the clay land became too much saturated with moisture for folding. This is done, the land will be ploughed and left for spring corn, and the hoggets now go to a mixed soil farm, where they will be in Turnip folds, with a change to pasture whenever the weather renders it necessary.

Now these hoggets were not highly fed from the first, in point of fact they had no corn till autumn folding began. Hoggets forced to early maturity are being drafted to the butcher now, the other hoggets will then follow them towards the end of winter, onwards throughout spring and early summer. We have to remember all this when the lambs first begin eating, and to arrange the dietary according to their use upon the land. In any case sheep intended for the butcher—that is to say, wethers, ought never to be kept longer than sixteen or seventeen months, or beyond June or July in the second year. In writing thus we keep profit and loss specially in view and ignore fancy altogether. We mention this because we know that on many home farms sheep are kept for home consumption to the age of three and four years, but such practice is altogether apart from that of an ordinary farmer, and sheep kept to that age are to be regarded as an article of luxury. But even in this matter of keeping sheep till age imparts colour and flavour to mutton we avoid doing so at a loss by making a selection of the best of the ewes or over-age ewes that are drafted from the ewe flock every year. These old ewes if put upon sound pasture with a pound of crushed Oats daily soon come into fine condition for killing, and we have supplied the table of a connoisseur with such mutton to his entire satisfaction, especial commendation being bestowed upon the mutton for its colour, flavour, and delicacy. The latter quality, it must not be forgotten, depends very much indeed upon the management of the meat after it reaches the hands of the cook. A certain hotel at which we frequently dine on market days is famous for its saddles of mutton, and this high reputation is maintained simply by careful selection of the meat combined with judgment in keeping it and skilful cooking.

WORK ON THE HOME FARM.

Glad indeed are we to find all sorts of winter corn coming well above the surface—a good, full, strong plant, which the exceptionally mild weather has induced to grow freely, and some little feeling of

anxiety about late sowing and seed germination is now at an end. Soft seed is not necessarily immature. Of course it is practically unsaleable to corn dealer or miller, but if fully developed we desire nothing better for sowing. In point of fact germination of such seed is much more brisk than it is when the seed has been rendered very hard in a hot dry summer. Some of the Wheat was not sown in a satisfactory manner. We came upon one of our bailiffs this season sowing Wheat upon a Clover layer, which had only been ploughed a few days before the sowing. The land was wet and heavy, and in order to get sufficient depth of soil for the drills heavy harrows had been used, and they had pulled many of the sods green with Clover up in very rough fashion. When we came on the scene there was only about half an acre more to sow, and the bailiff was very confident he should be able to put the surface in order next spring. We agreed that he should finish, for the only loss if it failed would be a bushel or two of seed Wheat, and the experience gained might be worth very much more. We have heard of a light land farmer whose land is badly infested with Poppies harrowing the Wheat as soon as it was well up in order to destroy the pest. We seriously question the wisdom of this proceeding, for the young Wheat plant had so little hold of the soil as to be liable to serious damage now. If the harrowing had been left till spring, the Poppies might then be destroyed, and the Wheat would by that time have its roots so deep down in the soil that it could sustain no harm. Avoid ill-considered, rough-and-ready practice, say we. We have known much harm done to Barley in spring by a similar process of harrowing soon after the plant was visible to destroy Charlock. Due care must be taken to open water furrows across headlands into ditches, to ensure the speedy passage of all surface water from the land. Never suffer water to accumulate for want of such attention, as the crop is certain to suffer.

THE PLOUGH DRILL.

WOULD the writer of "Home Farm" in the Journal of November 8th, No. 2093, be good enough to describe in a future number the "single drill" which was used attached to a plough for sowing Winter Beans and Tares? An effective implement of this kind would be most useful to many small farmers, who are sometimes much inconvenienced by not being able to obtain the use of a large drill at the time most suitable for sowing his seeds.—GEO. PARISH.

[The correct name of the single drill is the plough drill. It consists of a tapering wooden spout open at top and bottom, with an arm at the top, which is fastened to the plough beam by a bolt passing through it and the beam, with a nut and screw at the end. At the bottom of the drill is a wheel with the axle passing through the drill, and having a wooden collar on that part of the axle inside the drill, with diagonal grooves around the collar. This wheel runs upon the land, the motion of the plough causing it to revolve, and the seed to pass out with a steady regular flow. The distribution of the seed is regulated by an internal brush, which is raised or lowered by means of a sliding arm and screw. There is a staple on the drill, and at the end of each furrow the drill is lifted and suspended by the staple to a hook on the plough beam sufficiently high to prevent the wheel from rotation, and so stop the flow of seed while the plough is turned. The price of the drill is 18s. It is a cheap, simple, and efficient labour-saving appliance, indispensable to all small farmers, and useful to every farmer. We have several of these drills at each of our large farms, and have found them of especial use this autumn.]

THE BIRMINGHAM CATTLE AND ROOT SHOW.—We are requested to say that the stand of Messrs. Webb & Sons, Wordsley, contained the finest displays of roots and seeds they have ever arranged at Bingley Hall, and was a prominent feature of the Exhibition.

REMARKS.

25th.—A little rain early, but not measurable; fair day, with a little sunshine in afternoon.

26th.—Overcast early; fine and bright after 10 A.M.

27th.—Wet morning; gale in afternoon, with frequent sunshine; fine night.

28th.—White frost early; fog all morning; wet afternoon and evening.

29th.—Overcast all day.

30th.—Heavy rain all day; fine night.

1st.—Bright fine day; clear night.

A warm and wet week, the night between November 24th and 25th exceptionally warm.—G. J. SYMONS.

HISTORICAL NOTES ON ORCHARDS.

THIRTY-FIVE years ago notes on orchards of the past were written by an able and very old acquaintance of ours; the fruit question, for there was a "fruit question" then, as now, was also discussed, and the condition of British orchards at that time described and lamented. In looking over those notes we have been interested, and as they refer to matters possibly not known to young men of the present day, and some of which matters their elders may have forgotten—namely, the duties imposed on foreign fruit and their effects on home prices; the reduction of those duties, and the consequent uprooting of orchards; the agitation for the re-imposition of the tax, and a parliamentary inquiry, with the examination of witnesses; the, to some, curious result that, after the duty was decreased to a nominal sum, the prices for Apples increased in our markets to figures then claimed as remunerative to growers—as all those items are interesting, and some observations thereon suggestive, we make no apology for placing them before our readers.

An important and practical deduction from what appears will be seen to be this—if an extension of orcharding was desirable then as a profitable occupation, and for meeting the wants of consumers with superior home-grown produce instead of by large importations of imported fruit, how much more desirable is it to extend fruit plantations now that prices for Apples are higher than they were in 1850, and for several years previously, as will be seen by the tabulated lists that will be given? We are constrained to say that at no time in the history of orcharding were the prospects brighter for planters, and good returns surer than at the present time. An ever-growing population will, and must, demand increased supplies of fruit, and if these are not provided at home they will be had from abroad, preference being given to the "best for the money," for it is not the habit of purchasers nowadays to ask where fruit is grown, for they do not care, but buy that which best suits them, come from whence it may. Whether this is the most agreeable or not to home growers, it is a home fact, and as such must be met. The whole question, then, of fruit production for the multitude resolves itself into a question of judgment in selection, skill in cultivation, and enterprise in supplying the markets with consignments that both in appearance and quality best meet the public taste. Let landowners recognise this, and they will perceive it is to their advantage to offer facilities for the cultivation of fruit, and growers of it will then know that it depends on themselves whether the money of consumers is to be "kept in the country" or go out of it for their daily supplies of what will be more and more recognised as healthy wholesome food. With these observations we introduce the notes referred to, which the writer of them little thought, when he penned them so long ago, that he would read them in the *Journal of Horticulture* in 1888. They are as follow:—

The interest which the study and cultivation of fruits have of late excited, and the importance with which they are likely to be regarded, induce us to give the subject that consideration which it appears to demand. There can be no doubt that is a subject which has of late years been too much lost sight of; and particularly since the duty of 4s. per bushel on foreign fruit has been removed, the growers seem to have thought that it is one which does not concern them. We shall now lay down a sketch of this branch of rural economy, and see how far they are acting with a due consideration

of their own interests in neglecting it. Our observations will be directed to the great orchard districts of Kent, which will furnish good evidence, however, equally applicable to other parts of the country.

It is upwards of 300 years since Richard Harris, "the king's fruiterer," planted his orchard, called "The Brennet," at Tenham, in Kent. This was not, as some say, the first orchard ever planted in Kent; neither was it, as some still more erroneously have stated, the first that existed in England. Fruit was grown for commercial purposes from time to time immemorial before then; but the reason why Richard Harris left his counter and his counting-house to become a Kentish fruit-grower was the very same that would induce many an equally respectable fruiterer of the present day to act similarly. It was this:—"Having observed that those plants which had been brought over by our Norman ancestors had lost their native excellence by length of time, and that we were served from foreign parts with those fruits: on that account, which he saw no reason for, as neither the soil nor the climate here were unequal to the bringing of them to perfection, determined to try a plantation here; for which purpose, having in 1533 obtained 105 acres of rich land, then called 'The Brennet,' he divided it into ten parcels, and then having with great care, good choice, and no small labour and cost, brought plants from beyond the seas, he furnished this ground with them in rows in most beautiful order."

The necessity for such a complete change of the system which had hitherto prevailed, and the success which attended this experiment were so great, that Tenham became the centre from which all the other plantations emanated. So extensive and rapid was the influence which this example had that Lambard, writing in 1570, says, this parish, with thirty others lying on each side of the great road from Rainham to Bleamwood, was, in his time, the Cherry garden and Apple orchard of Kent; and, further, that "the orchards of Apples and gardens of Cherries, and those of the most delicious and exquisite kinds that can be, no part of the realm (that I know) hath them, either in such quantity and number, or with such art and industry set and planted."

We shall not stay to inquire into the decline and fall of these orchards, nor shall we trace the causes which led to these results; but, in all probability, the trees were allowed to become aged, diseased, and unfruitful, a succession was not provided, and they became extinct. We are induced to believe that such was the case, for a writer of that time states that these orchards continued to exist till within memory, when the lucre of planting Hops prevailing, few of them were suffered to remain. From the fact, too, of the writers of the seventeenth century, among whom were Ralph Austen, Hartlib, Bligh, Evelyn, and Worlidge, urging so strongly the encouragement of orchard planting as being a matter which should engage the attention of the Government as well as private individuals, there is every reason to believe that the cultivation of fruits had, to a great extent, been discontinued and neglected. By the writings of these men a fresh impulse was given: new plantations were formed and new varieties of fruit introduced, the old varieties having been allowed to disappear with the old orchards. The new sorts were as superior to the former as the former were to those of which Richard Harris complained. But these new plantations were doomed, in their turn, to the same fate as all the others which preceded them; and so, in the year 1778, we find it said that Rainham had "within memory great plantations of Cherries and Apples, especially on the lands adjoining the high road, and to the northward of it; but the greatest part of them have been displanted some years since." And of Newington it is said, that it "was formerly the greatest part of it planted with orchards of Apples, Cherries, and other kinds of fruit; these falling to decay, and the price of Hops making them a more advantageous commodity than fruit, most of the orchards in the parish were displanted, and Hops raised in their stead."

We shall give one more instance; it is of Borden, where "the

and is fertile, and much covered with orchards, and some years ago, more so than at this time, many of them being decayed and worn out, were displanted." Now these orchards of which we have last spoken were, no doubt, those which were called into existence by the writers of the seventeenth century; but no regular systematic planting and successive cultivation of fruit trees seems ever to have been kept up in this country; whatever was done was brought about by urgency, and carried out with impetuosity, but no steady, continuous system of operation; and hence the state in which our orchards were at the close of the last century.

It will be perceived from the above observations that in one important respect the circumstances are the same now as then—orchard trees allowed to go to decay, and succession not provided, the practical result being an invitation to enterprising cultivators abroad to supply our markets with Apples. They have done so. But a reason for neglecting orchards appears to have existed upwards of a generation ago that is not advanced now—namely, the great profits attending Hop culture. Hops appear to have ousted Apples at one time; but times change, and it is not unlikely that Apples will to a large extent oust Hops in some localities, and be grown more extensively in others where Hop culture has not been pursued. The subject will be resumed.

CAMELLIA BUDS FALLING.

EVERY season many growers are disappointed through the buds of their Camellias falling prematurely, but the cause is often due to faulty culture and mismanagement. At this period of the year severe weather may be expected any day, and fire heat is often employed liberally to insure safety. The temperature is kept even higher during severe weather than previously, when the nights have been mild, and no fire heat was employed. The sudden change to a warm dry atmosphere is alone sufficient to result in the plants casting their buds. If frost could merely be excluded, having a temperature of, say, 35°, it would be better for the Camellia, but perhaps not so well for other plants in the same structure; therefore it is often necessary to maintain a temperature at night ranging from 40° to 45°. The plants must then occupy the coolest end of the house, and not be stood on an open stage formed with wood scantlings so frequently employed in greenhouses. Through such stages the warm dry air as it rises extracts the moisture from the soil as well as from the leaves of the plants, with the result that the buds fall directly or a short time afterwards. If the stage is covered with zinc, and one or two inches of moisture-holding material placed over it, such as ashes, gravel, cocoa-nut fibre refuse, or any similar material, it will be much better for the plants. When strong fire heat is employed, syringe the stems and foliage of the plants just before dark, and again in the morning if they are dry. If this is done, other conditions that will be pointed out being properly observed, the buds will not fall.

Failure not unfrequently occurs through attempting to force these plants into bloom by a given date. If the change from the one treatment to the other is sudden, the buds or flowers when half expanded are almost certain to fall prematurely. They will bear forcing, but the change must be gradual. Plenty of moisture must be applied both to the plants and the atmosphere, and in no stage must strong dry heat be maintained about them. More buds probably fall through trying to force the plants into bloom than from any other cause. The best and safest method of growing Camellias to yield their flowers early is to assist them early in the season to make their growth. One season's early growth, if the plants are kept under glass the whole of the year, will result in flowers by Christmas with cool autumn treatment. By growing them early for several seasons they can be had in bloom two or three months sooner. For the majority of people Christmas is early enough now that Chrysanthemums can be had in abundance through the whole autumn. Directly growth has been made the plants must be gradually hardened to cool, airy, and drier treatment until the buds form at the extremity of the shoots. At this juncture amateurs often place their plants outside for the remainder of the summer. This can be carried out successfully by those who are thoroughly familiar with every detail of the plant's requirements; but my advice is, Keep the plants under glass, and the buds will gradually develop, and two or three risks are avoided. When placed outside the time comes for housing the plants, and fatal results often follow. They are removed from a genial position and moist surroundings outside to ungenial air inside; perhaps stood on an open stage in a dry structure. This sudden

change is followed by a check to the plants, which ends with the flower buds falling.

Another certain cause of failure is allowing the plants to become dry at their roots. In no stage of growth should the soil become dry; it must not only be kept moist on the top, but through to the base. It is easy to err in watering by attempting to give just sufficient and no more. This often results in their getting too dry. It is safer to give a little too much than too little. At the same time the soil must not be rendered sour and unsuitable for the roots to work in by saturating it with too much water, or the buds are equally certain to fall.

Overfeeding with strong stimulants in the form of liquid manure will end in the plants throwing their buds. Always supply liquid manure in a weak state, and soot water is beneficial if given clear, not muddy. If less liquid manures were given, and some reliable artificial manures applied to the surface of the soil in small quantities, at intervals of three weeks or a month, fewer failures would follow. Camellias must have fertile soil, or they suffer from exhaustion, and the buds will fall the same as when overfeeding is practised.

Unripened wood is a certain cause of the buds falling. The wood ought to be brown to the tip by the time the buds commence forming, then other cultural requirements being supplied, the plants will be certain to retain them. Wood that is green part of its length instead of brown will retain the buds until a certain period, or until they attain a certain size, when off they come. Plants that make their growth early always set a greater percentage of buds, and also produce finer flowers than those that make their growth late in the season. Conditions of health and the food supply being equal in both cases.

Strong insecticides after the buds are formed invariably result in the plants casting them. One strong application might result in the buds falling, while two or three weaker ones might be given without the slightest injury. Plants that are allowed to become covered with insects are liable to lose their buds, however well they may be treated in other respects. If insects exist sponge them off, or brush them from the old wood, using a weak solution of soft soap and water, fir tree or lemon oil. After flowering they may be washed with a solution of petroleum and water, at the rate of 1 oz. of the former to each gallon of water; this will destroy scale and eradicate it, if persisted in during the season of growth. These are some of the chief causes of Camellia buds falling, but any check or a combination of causes will bring about the same unsatisfactory results.—WM. BARDNEY.

PLUM FUNGI.

Up to last year I had not been seriously troubled with fungi attacking Plum trees. I had made acquaintance with the gum fungus, which I have treated of in a previous article, also with "Bladder Plums," due to the fungus named *Exoascus Pruni*. This is fatal to the young fruit, and it is prudent to cut off and burn the infested parts, or the spores of the fungus will be scattered far and wide.

Plum trees also suffer from a form of mildew, which is also more or less destructive to the fruits of the Pear, Apple, Cherry, and Apricot. This is named *Oidium fructigenum*; the fruit of the Plum is sometimes made quite white with the fungus. The only palliative measure, as no cure is known, is lifting and planting in fresh loam. Application of freshly slaked lime mixed with the surface soil when the trees are lifted as deep as the roots allow is useful. Old mortar rubbish is no use, for it is essential that the lime act at once on the inert matter, whereby nitrate of lime is formed, presumably by the action of minute organisms—viz., bacteria. One-sixth of lime is a proper quantity, or 2 inches thick to mix with 10 inches depth of soil. The lime passes into the trees, hardens the wood and buds, which assists the fruit to repel the fungus.

Plum leaves are sometimes covered with a white coating of the nature of an *Oidium*, but the fungus is named *Podosphaera tridactyla*. This, though not uncommon, is not particularly injurious, and yields to a sulphur and lime solution—viz., equal proportions of sulphur and quicklime with double the weight of both of water, or 1 lb. of sulphur vivum and 1 lb. of quicklime to five pints of water, boiled ten minutes in an earthen vessel, stirring all the time, allowing to settle, then pouring off the clear liquid, and keeping in well corked bottles. Half a gill may be added to three gallons of water, mixed, and applied with a syringe to the infested trees. Syringing with a carefully prepared sulphide of potassium is equally if not more efficacious. My chief object in writing is, however, to draw attention to a greater enemy than the

foregoing, which has defoliated some Plum trees and spoiled their crops. This I shall describe as the "red fungus." The leaves of the trees attacked have fleshy, somewhat irregularly rounded red spots, which scientists state are the work of a fungus named *Polystigma rubrum*. These spots enclose numerous asci, each containing several spores, besides which there are sporidia, and both open by mouths on the lower surface of the spots. If a thin slice of the leaf be examined with a microscope the tissues are seen "choked" with the filaments of the fungus, very different from a thin slice of a healthy leaf similarly examined. The fungus takes its nourishment from the leaves, the measure of injury being proportionate to the number of the spots.

Last year a few red spots only were noticed here and there on the leaves. The enemy was despised—it was in our power and allowed to escape. Nothing is so fatal, for when plunder is the object the few that are treated with immunity are certain to increase incredibly and beset the host plant. I have ever found it so with red spider, thrips, aphides, grubs, caterpillars, and fungi. Let those and other pests have their own way and they soon show what numbers can effect in devastation. Neglect of removing and burning the few leaves that were infested with the red spots in 1887 resulted in 1888 in the red spots being more numerous on individual leaves; and so many of the leaves were attacked that to pick off the worst infested meant stripping the trees as bare of leaves as the caterpillars had the Apple trees outside. The Plum trees are in a glass case having a south aspect. It was simply a matter of surrender—letting the fungus have its own way. Well, it caused most of the leaves to fall early, in fact the trees were as good as defoliated by early September. That the fungus appropriated the nourishment in the leaves and prevented them performing their proper functions was exhibited very decidedly in the fruit, which, though it swelled to a good size, began to shrivel at the stalk end when under ordinary circumstances it should have perfected, and it was unfit for food.

Whether the fungus took possession of the fruit as well as the leaves I am not capable of stating, yet the fruit had minute red spots at the stalk end, and internally the flesh was pervaded longitudinally by threads, which had destroyed and given it a reddish tinge. The fruit was remarkably sweet to the palate at first, but soon assumed a bitter and nauseous taste; most disagreeable, however, when swallowed, the stomach being made very uneasy. I have noticed similar sensations follow eating Figs that had red spots at the end of the fruit, also Peaches with one or more similar red spots at the apex, and very commonly in Melons with spots on the fruit. The flesh in all cases shrinks where the spots are, and ultimately decays. Such fruit ought never to be eaten; but what relation, if any, there may be between the red spots on the Plum leaves and the diseased fruits I do not know. There was nothing for it but to collect the leaves as they fell and burn them. Some say there will not be any fruit another year. That remains to be seen, for the trees have ample fruit buds, and the wood is firm and ripe. The border had a dressing of hot lime last autumn, and farmyard manure, and I shall expect a full crop of Plums?

How came the fungus? It attacked the upper part of the trees and descended. Perhaps it came through the top lights—certain it found a fitting host come from whence it may, and that is only what is needed to be known on that point. From the Plum case it spread to trees on a wall with an east aspect, and took the whole wall before it from the Plum case onward. The tree next the Plum case on the wall is a Purple Gage, which was most affected; the fruit, however, ripened, the leaves falling soon after. The fungus was less and less as the distance from the Plum case increased, and in effect was most disastrous to the dessert varieties; in fact Victoria escaped, and so did Coe's Golden Drop, and finished at the eighth tree from the Plum case, where was a break in the continuity by Fears before other Plum trees were reached. All other Plum trees were free from the fungus, both against walls and in the open. "Oh! but they will be attacked another season." Perhaps so, but unless the season be such as it was in 1888 from mid-June to well-nigh September, sunless and continually dripping, I fear no red fungus damaging Plum trees to the prejudice of the crop, neither on the trees that were so badly attacked this season, as it seems to revel in disorganised tissues, badly elaborated unassimilated sap. The fact of the matter is just this—the season was cold and wet, and we kept the Plum case much too close to oblige some Tomatoes, with the result that we had neither Plums nor Tomatoes. That comes of serving two masters and getting satisfaction from neither. Everybody knows Plums like cool treatment and as much air as a mountain Daisy, and then there is no healthier or more fruitful tree grown under glass; but, of course, everybody knows all that and much more, only I do not remember anything particular being

recorded of the "red fungus" attacking Plum trees to the extent of their defoliation and destruction of crop.—G. ABBEY.

AMONG THE NOVELTIES.

I TRIED a fair share of the new varieties of vegetables, &c., during the past season, and now proceed as heretofore to give my experience of them, trusting my few remarks may be a guidance to those who soon will be looking over their catalogues of seeds, each with very glowing descriptions appended to every novelty. May I ask why it is thought necessary to state that the new variety is better than any other in cultivation? This is the rule of some in describing their novelties, but I think the old stager soon finds out on whose description he can rely, and in whom no reliance can be placed. For myself I usually attach more importance to a soberly worded one than to the "lick all creation" style of thing we are growing accustomed to see—the wonderful crop of Potatoes delineated in an advertising illustration last season to wit. To my task.

TOMATOES.—Of these I tried several new strains, Henderson's Dwarf Champion, Thorburn's Volunteer, and the older varieties Aeme, Trophy Improved, and Livingstone's Perfection, the seed of which I received from New York. Champion is a dwarf, very strong stemmed variety, which is supposed to support its own weight, but which it failed to do with me. The fruit is of the Aeme colour, and I have discarded it. I had one plant of Aeme bearing scarlet fruit, and as it is a good cropper and the fruit of good flavour I kept the seed. I do not eat the fruit raw, but as I found the slugs only ate Aeme and the Old Red, I concluded they were the sweetest, the slugs being, as I know too well, good judges of quality. Volunteer is good in every respect, scarlet, and of the Perfection type. I shall grow it again. Livingstone's Perfection and Reading Perfection are exactly the same. I also received a packet from Mr. Gilbert of his Surpasse, and this I found a heavy cropper, the fruit being handsome and of good colour. They do not run to a large size (with the exception of a few plants which bore fruit of a different type), and I found them the most saleable of any, for size is objected to here, and I had to sell 10 ozs. fruit as half-pounders to get rid of them. A friend of mine liked Surpasse better than any other, and it will be my sheet anchor in the coming season.

POTATOES.—Laxton's Bouncer and No. 1, Railway Rival, Pink Beauty, Colonel and Captain sent me by Mr. Gilbert were all good, and of these No. 1 is a first class Potato, handsome, great cropper, and early. Bouncer late and good in every way. I like these two best of the six. Pink Beauty is as its name implies, and will be found very useful for a collection. Universal and Table King received from Messrs. Daniels are both good, but the latter is to my mind the best, and will be found to provide good dishes for the table, and the criterion after all is the eating. Ashleaf Seedling, a variety I received from Worcestershire, is, I consider, an improvement on all other Ashleaf Kidneys in earliness, cropping, and appearance. Sharpe's Victor and Duke of Albany were very disappointing this season. Sutton's Satisfaction and Masterpiece were both good, but the former is far and away the best, and if I were to pick out two Potatoes for main crop, I should choose that and Bouncer. Some seedlings, Village Blacksmith, Covent Garden Perfection, &c., were all unsatisfactory, and I have discarded them. Imperator is a good field Potato, but the soil must not be very rich or the tubers will grow far too large for table use.

Ne Plus Ultra Runner Bean is a gem for exhibition, the pods being very long and as straight as a gun barrel.

Rousham Park, New Anglo-Spanish, and Wroxton Improved were the Onions I grew, and the second produced the finest bulbs, and will be found the best for exhibition, but for general purposes give me the last, for the bulbs are thicker, and being more globe shaped will probably keep better. Three better Onions could not, I think, be grown. I had thought Rousham Park could not be beaten.

BRUSSELS SPROUTS.—I am trying the Wroxton, but do not consider it better than many other strains.

Sutton's White Heart Cos Lettuce grows to a great size, does not run to seed quickly, and is very good. It will be found useful for exhibition.

In Peas I was most pleased with Sharpe's Victory, the pods very dark green, large, and plenty of them, the height being 2½ feet. The quality also is first rate. The only other Pea worth mentioning is not a new one, but it ought to be grown by all, Wordsley Wonder, which is a great cropper of first quality. The pods are curved and look thin, but when opened they disclose ten and eleven large peas, packed very closely together. This is not all pod and no inside.

Pen-y-byd Marrow cannot be beaten for a gentleman's table,

prolific, and the fruit of good quality. Universal Savoy, early, sweet, and compact.

I am afraid I have trespassed too far on space, and shall be cut down considerably, so pull up and beg the Editor's pardon.—H. S. EASTY.

[Granted.—ED.]

LILIUM AURATUM.

THERE is a probability of this fine plant becoming as common as the Dutch Hyacinth; few owners of a small greenhouse failing to grow it, and as it can be had so very cheaply, no doubt more of it will be cultivated. The present is the time to secure a stock of bulbs, those newly imported being now plump and full of vitality. In choosing bulbs, the most vigorous stems will be found to be produced by those which are close in the scales and heavy for their size. Indeed, if the bulb be of a good medium size it is doubtful whether the large bulbs are worth the extra money they realise. All things considered, there is perhaps no better time for potting the bulbs than this month; but I have kept them well into spring, and secured healthy plants, which flowered late in the season, and at a time they were very useful.

Some growers complain of the difficulty of establishing imported plants; but if managed as I shall presently indicate, I am sure, from my own experience, that few losses will occur. Imported Lilies, it should never be forgotten, suffer a very great check through loss of roots, a healthy plant never being inactive at the roots. In endeavouring to establish these it is consequently very necessary to treat them gently. I treat them as follows:—The compost employed is very open, such, for instance, as a mixture of loam two parts, leaf soil one part, and sand one part; a little loose peat is beneficial where it is to be had good. The size of pot is of consequence, and here many make the mistake of putting the bulbs in those which are too large. A large plant can be most successfully grown in a pot 6 inches in diameter, and the following autumn will find it filled with roots, ready to be repotted without disturbing a root, a point of great importance. I do not use much drainage, and place just a little of the compost between that and the base of the bulb, so as to leave room for a good surface dressing in summer. When the bulb is placed in position a little more compost is put in about half way up the bulb, the upper portion being left bare. The soil is used in a suitable condition as to moisture, so that no watering is needed.

When all are potted, they are placed in a cool structure and thickly covered with dry leaves, and a mat over these to keep everything neat and tidy. A covering of bracken may be substituted for the leaves; but on the whole, I think leaves preserve a condition of steady coolness better than anything. I find the plants may be left until the end of January or the beginning of February, when, if the weather is open, it will be necessary to examine the soil in case it may be getting dry. A small amount of water given to each will put them all right, especially if the leaves are slightly damped at the same time, and turned back again over the bulbs. By March the rooting process should have proceeded to a good extent, and many of the bulbs will be throwing up their growths. Another watering will most likely be needed, and then a slight surfacing of fresh soil, giving but just enough to bring the soil level with the top of the bulb. Those unstarted will be better under cover awhile longer. It will be noticed that so far the treatment has been of a nature to ensure to the plants a cool moist rooting medium.

I find nothing so damaging as water being continually applied; yet the roots must have an unstinted supply of moisture in order to keep the bulbs plump. That being so, a position where the pots can stand without danger of continual dryness must be sought out. Direct sunshine on the pots is very prejudicial, and where it is impossible to avoid this, a thick layer of moss placed on the surface of the pots will be found useful. As the stem roots are produced some more soil should be placed in the pots, rough bits of turf and peat are best then. At the flowering period the plants will do with less water, but the soil should never become really dry; and as soon as the new roots from the bulb are seen to be in course of production, the plants should be shifted on into larger pots. If properly managed the ball will be completely matted with roots, and without disturbing any of these place the plant in the new pot, so that only a very thin layer of soil will lie between the bottom of its ball and the drainage. This time, and in future years, the bulb will be, of course, covered with soil. The best place to winter the plants I find to be a perfectly cool structure, the pots being plunged and covered deeply with ashes.

As already hinted, the bulb may be for a good time without starting. When this is the case, a very efficient method of growing the plant is to prepare ordinary cutting boxes, or if there are very many bulbs, the bottom of a cold frame, by placing a couple

of inches of sifted leaf mould, and on that the base of the bulbs thickly together. A thick layer of moss is laid above the bulbs, and an occasional watering given until a good quantity of roots are formed, when the plants are lifted carefully with as much soil as possible and potted. Very good results follow this rough and ready method.—B.

OLD GOOSEBERRY BUSHES.

THERE are two good reasons why degenerated bushes should be discarded, the first being that they occupy much valuable space, and the second that they do not give returns sufficiently good to pay for their culture. I have seen many old bushes occupy a space from 4 feet to 6 feet square. A dozen of them would take up more ground than would accommodate a score of thirty healthy trees, and every one of these would give a weight of fruit exceeding that secured from the old ones, while in quality there is no comparison. As everybody knows, old bushes only bear small fruits, thick in the skin, juiceless, and flavourless, while the young ones swell up to their fullest extent, being thin in the skin and full of rich pulp, bringing the highest price in the market, and are most relished at dessert. Gooseberries can never be too large. Possessors of old worn-out bushes may say, "Well, you know, they do not occupy valuable ground, as that piece is good for nothing else." But this is far from being correct. No excuse for harbouring old bushes should be accepted. The fact of the matter is there is no part of a garden that cannot be made to produce good Gooseberries, and the bushes in question would, no doubt, give the best results before they became incapable of doing so. Apart from having healthy bushes, there is no secret in growing the finest Gooseberries. I know cottagers who annually have them as fine as in the largest gardens, and this is certainly not from extra skill in culture, but they have found that the best fruit is invariably produced from bushes that have not begun to degenerate, and act accordingly. Fine young bushes of all the best varieties of Gooseberries are cheap enough to be within the reach of all, and the present season should be taken advantage of to clear out every bush that is past its best.—A KITCHEN GARDENER.

THE NATIONAL ROSE SOCIETY.

THE annual general meeting of the above Society was held in the Hotel Windsor, Victoria Street, Westminster, on Thursday last, December 6th, at 3 P.M., Dr. Robert Hogg, one of the Vice-Presidents, in the chair. There was a large attendance of members, those present including the following:—The Rev. H. H. D'Ombraim and E. Mawley, Esq. (Hon. Secs.), T. B. Haywood, Esq. (Hon. Treasurer), Colonel F. S. Hore, Captain Christy; the Reverends W. Wilks, J. H. Pemberton, Alan Cheales, H. A. Berners, F. R. Burnside, F. Page Roberts, F. Gall, and A. Foster-Melliar; and Messrs. G. Paul, J. Rawlins, W. J. Jefferies, E. B. Lindsell, R. Harkness, J. Brown, G. Bunyard, B. R. Cant, A. Prince, C. E. Cant, W. Paul, T. W. Girdlestone, J. Cranston, F. Cant, J. Burrell, W. Rumsey, G. A. Marshall, G. Mount, R. E. West, R. Bloxham, A. Slaughter, E. Wilkins, G. Prince, A. Turner, J. D. Pawle, and H. Appleby.

The business was commenced by Mr. E. Mawley reading the circular calling the meeting, and then, at the suggestion of the Chairman, the minutes of the last meeting were taken as read. Messrs. G. Paul and A. Slaughter were next appointed scrutineers of the ballot for officers and members of the General Committee for 1889, and this proposition induced Mr. B. R. Cant to make a few observations respecting the desirability of more names being submitted for the General Committee to supersede some of the members who rarely or never attended the meetings during the past year. The Rev. H. D'Ombraim explained that it was the rule half the members of the Committee should retire each year, but that they should be eligible for re-election. He further pointed out that the matter had been before the Executive Committee, and if any suggestions of this character had been made then, or names submitted, they would have received every attention. Mr. Cant said he had been unable to attend the Executive Committee meeting in question, and he wished to submit the names of Dr. Budd of Bath, Mr. R. N. G. Baker of Exeter, and Mr. H. J. Veitch of Chelsea, as members of the General Committee. Mr. Cranston thought it was desirable some alteration should be made in the Executive Committee to give others an opportunity of attending. They knew nothing of what had been done, and he considered they were justified in expecting a report of the business performed. Mr. D'Ombraim said in reply it would be unusual and undesirable to publish reports of the Executive Committee meetings. Dr. Hogg called attention to the fact that there was a note on the balloting paper to this effect—"Members are requested to alter any names of either the retiring or newly

proposed members of the Committee according to their wishes." He considered this was sufficient, and he suggested that in future the names of proposed members should be sent in before the annual meeting.

Mr. D'Ombraïn then read the following report:—

REPORT OF THE COMMITTEE FOR THE YEAR 1883.

In presenting this report to the members, the Committee do so this year with peculiar satisfaction, it being their very pleasing duty to announce that Her Royal Highness the Princess of Wales has graciously consented to become the Society's Patroness. It is due, however, to their indefatigable Vice-President, the Hon. and Rev. J. T. Boscawen, to state that it is in a great measure owing to the kind interest he has taken in the matter that this honour has recently been conferred upon the Society.

The past Rose season has been a very unfavourable one for exhibitors, owing to the cold, wet, and sunless character of the spring and summer months. Consequently, the flowers staged at the Society's two shows, although as numerous as ever, were as a rule lacking in quality and finish. The Metropolitan Exhibition was, for the first time for some years, held at the Crystal Palace—which in the opinion of the Committee, is, all things considered, the most suitable building in or near London for the purpose. Although not quite as accessible as some other places that might be selected, it, on the other hand, possesses many special conveniences for holding an extensive display of Rose blooms, such as the liberal schedules issued by the Society invariably bring together. Notwithstanding all the drawbacks of an untoward season, it was a grand Show, and under the experienced supervision of the Garden Superintendent, Mr. W. G. Head, all the necessary arrangements were carried out with exceptional completeness. The Provincial Exhibition at Darlington, although somewhat marred by the unpropitious character of the weather, was undoubtedly one of the best Rose Shows of the year, and great credit is due to Mr. E. R. Whitwell for the admirable way in which everything connected with it was managed.

During the past year a supplement to the Society's catalogue, containing a specially selected list of the varieties which have been sent out since the catalogue itself was published four years ago, has been issued free to members. Copies of both catalogue and supplement are now on sale, and can be obtained on application to either of the Hon. Secretaries.

After the annual general meeting last year, a meeting of the secretaries of societies affiliated to the National Rose Society was held, which, considering it was the first gathering of the kind, was well attended. The object of this meeting was to arrange as far as possible a list of Rose shows for the ensuing year. It is sincerely to be hoped that at a similar meeting, which will take place at the same time this year, some more definite arrangement may be come to by which the suicidal clashing of Rose show fixtures might next season be prevented.

FINANCIAL STATEMENT.—Taking into consideration the unusually large amount expended during the past year in prizes, and the cost of publishing the supplement to the catalogue, the financial position of the Society remains very satisfactory. The receipts from all sources, the total expenditure, and the balance in the Treasurer's hands, may be seen below.

ARRANGEMENTS FOR 1889.—The arrangements made by the Committee for 1889 are as follows:—The Metropolitan Exhibition will again be held at the Crystal Palace, the date being Saturday, July 6th; while it has been decided to hold the Provincial, or Northern Exhibition, in the Sheffield Botanical Gardens, on Thursday, July 18th. The Society has already held two Rose Shows at Sheffield, the first time in 1881 and again in 1883, and on both occasions has received a warm welcome and generous support. The Committee of the Sheffield Botanical Society have entered so heartily into the idea of a third Exhibition being held there, that there is every prospect of it proving an unusually successful one. Moreover, the locality selected for next year's Provincial Show is centrally situated and easily reached by rail from most parts of the Kingdom.

During the course of next summer the Council of the Royal Horticultural Society propose holding a Rose Conference in their Gardens at Chiswick, and has invited the co-operation of the National Rose Society. It is as yet too early to state anything very definite respecting this gathering of rosarians, but it has been understood that it will follow somewhat on the lines of the recent Apple and Pear Conference. Should this be the case, Roses will no doubt be largely exhibited for the purpose of classification, while papers will be read and discussions held. The Committee cannot but regard a Conference on Roses, such as that suggested by the Royal Horticultural Society, as a step in a direction much needed, and as likely to lead to valuable results, which could not well be secured in any other way. They have accordingly appointed a Sub-Committee to co-operate with the Royal Horticultural Society in this matter.

MEMBERS' PRIVILEGES.—As in former years, subscribers of £1 are entitled to two private view tickets and four transferable tickets admitting at the same time as the general public; while subscribers of 10s. are entitled to one private view and two transferable tickets. New members will each receive a copy of the Society's Illustrated Catalogue of Exhibition and Garden Roses, together with a copy of the Supplement issued during the past year.

In conclusion, the Committee desire to present their best thanks to their local Secretaries, and especially to those who by their zeal and energy have contributed so much towards advancing the Society's interests.

The Chairman then requested Mr. Haywood to read the balance-sheet as follows:—

NATIONAL ROSE SOCIETY.

BALANCE SHEET, YEAR ENDING 30TH NOVEMBER, 1883.

RECEIPTS.	
December 1st, 1887.	
Balance at Bankers	48 3 2
Subscriptions	311 1 0
Donations	5 0 0
Cheque Unpaid last Year	0 15 0
Affiliation Fees and for Medals from Affiliated Societies	74 19 0
From Crystal Palace Company	165 0 0
" Darlington	100 0 0
Special Prizes	8 10 0
Sale of Catalogues	1 11 8

£354 19 10

EXPENDITURE.	
Printing, Stationery, and Advertising	36 5 3
Postage, Telegrams, Messengers, and Sundry Expenses	26 19 11
Secretary's Travelling Expenses to Arrange Shows	7 1 0
Expenses Crystal Palace Show	8 1 6
" Darlington Show	6 17 6
Medals	5 8 2
" for Provincial Societies	59 14 6
Prizes Crystal Palace Show	294 0 0
Prizes Darlington Show	145 5 0
Prizes South Kensington Show last year	0 5 0
Assistant Secretary and Accountant	20 0 0
Balance at Bankers	41 2 0

£674 19 10

The Chairman submitted the report to the meeting, and proposed that it be adopted, printed, and circulated, which was seconded by the Rev. A. Foster Melliar, and carried unanimously. The Rev. H. A. Berners of Ipswich called attention to what he regards as excessive charges for the Society's medals, and thought some reduction should be made. Mr. D'Ombraïn said in reply that the National Society only charges the actual cost of the medals.

Mr. B. R. Cant moved, and the Rev. F. Page Roberts seconded, a resolution to the effect that the best thanks of the National Rose Society be communicated to the Committee of the Horticultural Club for the use of their rooms during the past year, which was carried unanimously. It was proposed by Mr. G. H. Marshall, and seconded by Mr. R. E. West, that the thanks of the Society be given to the officers and other members of the Committee for their services during the year, which was carried by acclamation.

A somewhat important matter was then introduced by Mr. E. B. Lindsell in the form of a proposition, seconded by Mr. T. S. Girdlestone, that the word "habitually" be omitted from regulation 13, which reads as follows:—"No person should be allowed to compete as an amateur who habitually sells Rose plants or Rose blooms, nor any person in the employ of a nurseryman. Any objection raised as to the rightful qualification of an exhibitor should be referred to the Executive Committee for arbitration, and their decision shall be final and binding on both parties." Mr. Berners advocated the insertion of the words "at any time" in the place of "habitually." Mr. B. R. Cant thought this was not advisable, as anyone who had sold in the past would be excluded, and that was not intended. Questions were also asked as to whether gardeners selling Rose blooms at shows, or amateurs selling their blooms for charitable purposes, would exclude them from the amateur classes. To which negative replies were given, and Dr. Hogg said if the word "habitually" were struck out the other cases could be dealt with as they arose. The resolution was then adopted.

Mr. D'Ombraïn proposed that the best thanks of the meeting be given to the Hon. and Rev. J. T. Boscawen for having interested himself in securing the patronage of the Princess of Wales for the National Rose Society, which was seconded by Mr. Cheales and carried unanimously.

The Chairman then announced that the following had been elected as officers and members of the General Committee for the ensuing year.

President.—The Very Rev. the Dean of Rochester.

Vice-Presidents.—The Hon. and Rev. J. T. Boscawen, Rev. J. M. Fuller, Robert Hogg, LL.D., and James McIntosh.

Hon. Treasurer.—Thomas Burt Haywood.

Hon. Secretaries.—Rev. H. Honeywood D'Ombraïn and Edward Mawley.

General Committee.—H. Appleby, J. Bateman, Rev. H. A. Berners, R. Blexam, G. Bunyard, G. Burch, Rev. F. R. Burnside, J. Burrell, B. R. Cant, F. Cant, Rev. A. Cheales, Captain Christy, W. F. Cooling, J. Cranston, Rev. A. Foster Melliar, Rev. F. H. Gall, T. W. Girdlestone, W. J. Grant, T. B. Hall, R. Harkness, J. Shirley Hibberd, C. F. Horc, W. J. Jefferies, E. B. Lindsell, G. A. Marshall, M. T. Masters, F.R.S., Rev. F. Page-Roberts, G. Paul, J. D. Pawle, Rev. J. H. Pemberton, G. W. Piper, A. Prince, W. Rumsey, A. Slaughter, A. Turner, R. E. West, E. R. Whitwell, E. Wilkins, Rev. W. Williams, and W. H. Williams.

Hon. Auditors.—J. D. Pawle and F. T. Wollaston.

Some discussion followed respecting the provincial Show for 1890, and Mr. D'Ombraïn stated he had been in communication with Mr. Walter Chamberlain respecting another exhibition at Birmingham, and this seemed to meet with general favour. Mr. Berners again brought up the subject of reducing the cost of the medals, and suggested that the matter be referred to the Executive Committee. It was stated that the silver medal of the Royal Horticultural Society, which is now struck at the Mint, costs only 11s. 6d., whereas, when struck privately it cost the Society 21s. Mr. Berners' suggestion was supported by Mr. Cheales and carried.

A cordial vote of thanks to Dr. Hogg was then proposed by Mr. Pemberton, seconded by Mr. Mount, and carried unanimously, bringing the

business of the meeting to a conclusion. A meeting was, however, subsequently held of the General Committee and representatives of the affiliated Societies to make some arrangements with respect to the dates of shows. The annual dinner was also held in the same hotel at 6 P.M., Dr. Hogg in the chair.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 11TH.

THE last meetings of the year of the Fruit and Floral Committees were well attended by the members, but the exhibits were comparatively few. The slight frost and somewhat heavy fog were not favourable for the movement of tender plants, and only those of a hardy nature were, with a trifling exception or two, brought to the hall. The most effective group was formed of finely berried plants of a new *Skimmia*, and in the vegetable department the greatest extent of space was occupied with collections of Turnips and vegetables from Chiswick. At the close of the respective meetings unanimous votes of thanks were accorded by the members of the Committees to the Chairmen for the year, G. F. Wilson, Esq., F.R.S. (Floral), and Dr. Robert Hogg (Fruit), which these gentlemen responded in pleasant and appropriate terms.

FRUIT COMMITTEE.—Present: Dr. Robert Hogg in the chair, and Messrs. H. J. Veitch, W. Warren, W. Denning, J. Burnett, Philip Crowley, G. T. Miles, Harrison Weir, J. Wright, R. D. Blackmore, Sidney Ford, C. Howe, C. Ross, and W. Marshall. Mr. R. Gilbert, Burghley, sent specimens of the Universal Savoy and Chou de Burghley, both in the best condition, and a vote of thanks was awarded. Messrs. W. & J. Brown, Stamford, sent a seedling Apple of medium size and good appearance, but it was not considered an advance on existing varieties. Samples of *Asparagus Chicory* were again sent by Mr. Willard from Holly Lodge, Hampstead, and presented in a cooked and uncooked state. It was considered a distinct and wholesome vegetable, and accorded a first class certificate. Mr. W. Blackmore, Dereford Gardens, Exeter, sent a seedling Apple Queen of the Exe, bearing some resemblance to Cox's Orange Pippin, but though it was said to keep later it was by no means equal in quality to that variety, and was passed by the Committee. Mr. Campbell, The Gardens, The Priory, Rochampton, sent admirably grown and blanched examples of Batavian Endive, and a cultural commendation was awarded. In the collections of Turnips above referred to, Yellow Finland (Vilmorin) appeared to be the best of the yellow sorts, small, neat and good in quality, and Model (Wrench and Watkins & Simpson) the best of the whites. The Brussels Sprouts which were grown from seed supplied by Mr. Peter Barr were mostly overgrown, and the smaller and compact forms were the most approved, notably the French Superior, Roseberry, Imported and Wroxton, this last, however, being somewhat larger than the preceding, but the knobs were uniform in size and firm. A report of the trials will be prepared by the Superintendent.

The report of the sub Committee appointed to conduct experiments in the cold storage of fruit was presented, and was not on the whole of a favourable character, the keeping properties of some kinds of fruit being materially prolonged, while others, notably Melons and Tomatoes, entirely failing. The chamber was not considered suitable, the atmosphere not being sufficiently dry for the purpose, nor so sweet as was desirable. With a dry atmosphere and equable low temperature there is no doubt that the keeping of hardy fruit can be materially prolonged. The report is placed before the Council of the Society for consideration.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq. (in the chair), and Messrs. W. Bates, H. Herbst, W. Holmes, B. Wynne, R. Dean, J. Dominy, H. M. Pollett, J. O'Brien, H. Ballantine, E. Hill, and Rev. W. Wilks. A number of plants from 1 foot to 2 feet in diameter, of *Skimmia Foremanii* were exhibited by Mr. Foreman. The variety was raised at the Eskbank Nursery, Midlothian. The plants were sturdy yet vigorous, with dark green leaves, and quite covered with bunches of bright scarlet berries. Such specimens possess great decorative value. Plants are said to have been uninjured by 32° of frost, and the berries are retained (some of them, presumably) from eighteen months to two years. A first class certificate was awarded. A similar honour was accorded to *Primula Swanley Pink*, exhibited by Mr. Cannell. The plant is of sturdy habit, and the flowers large, well formed, and of good substance, colour delicate blush pink and very pleasing. Mr. Cannell also placed flowers on the table of others of his Primulas, and one of these, *Swanley Giant*, appeared identical with Great Western, for which Messrs. J. James & Son were accorded a vote of thanks. Similar votes were accorded to Mr. R. Dean for plants of hardy coloured Primroses, flowering profusely; to Messrs. Collins Brothers & Gabriel for Carnation White Andalusia, pure and sweet; to Mr. Odell, Hillingdon, for Cyclamen Rosetta, very fine, rosy mauve; to Mr. Rowe, Nunfield Gardens, Dumfries, for a pale form of *Pleione maculata*; and to Mr. Heath, Cheltenham, for two seedling *Masdevallias*.

SOFTENING HARD WATER.

THOSE persons who have a good supply of soft water for horticultural purposes know nothing of the difficulties attached to the use of hard water. The cultivation of plants and fruits where only water from wells or water companies' pipes is obtainable is not readily rendered successful. Water from chalk wells is the worst of all if convenience does not exist to soften it before using, or even to allow it to stand in the sun for a time before applying it to plants. I have noticed that during a hot season, plants—Chrys-

anthemums, for instance—assume a much more sickly appearance of the foliage than they do in a wet season, which proves to me that cold hard water plays an important part in the colour of the foliage. Particularly does cold hard water affect the leaves of Azaleas at all times of the year. Where nothing but water from chalk is available, the sediment left on the leaves of Crotons, Dracenas, or any other fine-foliage plants which are daily syringed with this water causes much disfigurement, as the sediment is most difficult to remove, even with the aid of softsoap.

To lessen these difficulties means should be taken to soften the water by some process. Where exposure to the sun of a quantity of water, say from 500 to 1000 gallons, in tanks, can be adopted, much may be done to improve hard water by adding some softening matter. Where the demand for water is not so great, the amateur can, by the aid of several petroleum or other casks, insure a supply of softened water. Water which contains a large per-centage of carbonate of lime in solution is bad for plants, and should be softened before using. A very good test for hard or soft water is as follows:—Dissolve a small quantity of good soap in alcohol. Let a few drops fall into a glass of water. If the soap coagulates or thickens, the water is hard; if it does not coagulate, it is soft. If common washing soda be used, at the rate of a quarter of a pound to 36 gallons of water (first dissolving the soda in hot water), allowing the water to stand twenty-four hours, the chalk, which was before invisible, will be precipitated to the bottom of the tank, and the soda acts as a stimulant to the plants. When using the water from the tank care should be taken not to disturb the sediment at the bottom.

Another method of softening water on a larger scale is by the use of anticalcaire, more commonly called milk of lime. To 250 gallons of water add 1 lb. of the latter, allowing it to stand for twenty-four hours, when the chalk will be deposited at the bottom of the tank and the water rendered soft. If the tank were fitted with a tap 6 inches from the bottom the softened water could be run off into other vessels without fear of disturbing the objectionable sediment at the bottom of the tank. Another tankful of water could be prepared also while the former one was being used, thus keeping up a constant supply of softened water. If lime in excess be added to chalk water the water becomes turbid, and the carbonate of lime, formerly held in solution, is precipitated, rendering the whole soft.—E. MOLYNEUX.

PEAS IN 1888.

FOR some years past you have published remarks of mine on the Pea crop. The past season has been peculiar for many crops, some it has suited, and many it has not; but 1888 has not been a bad Pea year. The earliest crops were a little later than usual, but they yielded a long succession: indeed, I do not remember a season when Peas continued bearing so long as they did this summer. As in many former years we had several new varieties on trial, but I do not purpose passing a definite verdict on these, as it was not the best of years for testing their habits and merits. For instance, we had one variety said to be limited to a height of 2½ feet, but it grew 4½ feet, and was no doubt forced out of its normal character by the superabundance of rain and dull weather. Some others which were said to pod and mature in the shortest time on record did not do so, and in these cases I am also inclined to give them the benefit of the doubt, and will try them another year.

Our early Peas consisted of William I., Alpha, Carter's Lightning, Day's Early Sunrise, Kentish Invicta, Alpha, and American Wonder. Carter's Lightning was ready first by seven days, and is very good in other respects; it was followed by Alpha; this by Kentish Invicta; and then came William I.; Sunrise failed to fill at the points, and we have discarded it; American Wonder came in about the middle, but it is too dwarf, and gave only a poor succession.

If the second early varieties are sown with the early crops they will form a useful succession. In this section Anticipation did not equal our expectations either as to earliness or productiveness. Paragon, said to be early, was not early enough; it is prolific, but not of the first quality. Duke of Albany I regard as the best of all Mr. Abbot's productions amongst Peas. It had a good character originally, and retains it still. It resembles Telegraph, but being wrinkled, is superior in flavour to that variety; its deep colour and fine size of pod render it good for exhibition. Evolution is showy, but not a favourite in the kitchen. I have grown Giant Marrow for years, and like it still. Telephone is also good. Stratagem and Pride of the Market do better in a somewhat dry than a wet sunless season, and were long in filling their pods this year. Wordsley Wonder has sustained its reputation. Walker's Perpetual Bearer did not bear longer than several others. Matchless Marrow fat has proved grand in flavour. Royal Jubilee is very large.

pod, but did not fill well this summer. Champion of England and Veitch's Perfection are still amongst the best in flavour, but behind many others in productiveness.

Late Peas we never had later than this year. We sent good dishes to the table until November 9th. Our garden is surrounded by trees. These confine the atmosphere, often resulting in much mildew on Peas. Lynn's Black-eyed Marrow (Dickson's) having been recommended as a mildew resister, two quarts of it were sown the same time as Omega, Ne Plus Ultra, and Latest of All, and besides resisting the mildew it continued bearing three weeks after the others had come to a standstill.—A KITCHEN GARDENER.

ASCLEPIAS TUBEROSA.

COMPARATIVELY few species of the genus *Asclepias* are cultivated in borders as hardy plants, and perhaps there are few that are really worthy of a place amongst the many attractive plants now grown in British gardens. No doubt can, however, be entertained respecting the merits

FIG. 58.—ASCLEPIAS TUBEROSA

of the plant represented in the woodcut, fig. 58. In warm soils and situations it thrives vigorously, especially if the natural drainage be good, and being readily increased fine clumps can soon be had. The flowers are bright orange-red, and are produced in dense corymbose heads at the tops of the stems, which are clothed with narrow sessile leaves. It forms compact bushy plants, 2 feet or so in height, and it can be increased by seeds or division of the tubers, the latter being preferable and quicker than the other; in fact, seeds are not produced with certainty.

NEW FACTS IN APHIS LIFE.

AMONGST the multitudes of insects that annoy the gardener and the farmer, the aphis tribe, I believe, must occupy the bad pre-eminence of being the most troublesome of all, minute as is their size. Few, indeed, are the plants entirely exempt from them,

and though these are often attacked by aphides without being killed, the exhaustive and disfiguring effects of their ravages are sadly conspicuous. Then their rate of increase is so marvellously rapid that were it not for the agency of their many parasitic enemies, and the influence of weather that is unfavourable to them, in a short time they would make the face of Nature a desolation. Prof. Huxley calculates that supposing the multiplication of aphides could go on uninterruptedly for 300 days and no more, "there would be no room in the world for anything else but aphides." This is the more remarkable when we compare what is the weight of an aphis and that of a human being, as Mr. Buckton reckons that two hundred millions of them would scarcely be as heavy as an average man. A forcible instance of the power of little things.

The fact is now well known to many persons who are neither naturalists nor gardeners that twice in the year there occur migrations of aphides, in the seasons of spring and autumn; possibly small migrations do take place at other times, but they are not of particular importance. The spring migration, which is usually during May, is, to appearance at least, associated with a peculiar condition of the atmosphere—an easterly wind, but not a strong one, and a heaviness in the air. On such days country folks are apt to say there is a blight in the sky, and though they may not connect these days with insect migration, in the remark there is more truth than they are aware of. A second, and in most years a greater, migration occurs during early autumn at the end of August or September. This migration, from some cause or another, perhaps owing to the destruction of many aphides by the heavy summer rains, went on to a very small extent this year in several places under my observation, and I expect a like scarcity of them was a general occurrence throughout Britain—out of doors, at least; but it will not do to relax one's vigilance, as insects have a trick of showing themselves unexpectedly. No doubt, in the course of these aerial journeys made by them (and small as are aphides, it seems that they sometimes travel several miles) quantities of them are eaten by birds, drowned, and killed in various ways.

More underlies the habit of periodic migration amongst aphides than we might suppose, and as a rule it seems to have nothing to do with a lack of food in the locality they are quitting. But it is evidently connected with a change of food in some species, though not in all, and as we get additional information about this we shall be the better able to cope with these enemies. Some of the older entomologists had a suspicion that aphides which suddenly appeared in swarms upon a particular species had not always come from some other plant of the same species, but from one very different, and they were right. *Siphonophora Chelidonii*, so named because it has been taken on the Greater Celandine, and probably occurring in allied species, also infests the Raspberry from June to October. *Siphonophora Pisi*, a large aphis, usually shining green, but occasionally mealy and brown, clusters by thousands on the Peas of our fields, though it is also noticeable on the common Nettle, the Shepherd's Purse, the Meadow-sweet, and other wild species. One of the aphides infesting Wheat, *S. granaria*, is believed to migrate during autumn to Grasses, though it is not ascertained where the eggs are deposited which produce the spring brood. A host of different names have been given to Aphis Rumicis from its various food plants. It is the "black dolphin" or "collier" of the country folk, infesting the Bean, but visiting other leguminous plants as well, in autumn, for instance, after retiring to the Furze to deposit its eggs. That notable foe of the Hop, *Phorodon Humili*, a bright green aphis, breeds in the spring upon the Sloe, probably also on the Whitethorn. There must be some migration in the case of *A. Amygdali*, the troublesome pest of the Peach and Nectarine, for after visiting the trees in spring, curling up the young leaves, it vanishes frequently for two or three months and reappears numerous during the autumn.

It is a curious circumstance in the history of each individual aphis that it cannot change its food. Naturalists have proved that one of the tribe will sooner die of starvation than imbibe the sap of a different species than that upon which it has fed. Hence when a swarm of aphides has travelled a long or short distance to settle on plants diverse from their former food they die on arrival, but produce a new brood, which continues the succession. The migrations, however, are not associated with the appearance of both male and female winged aphides, by the latter of which eggs are laid to remain unhatched till spring. Towards the end of autumn the females cease to produce living young, the low temperature, as is surmised, causing the development of the winged types and the laying of eggs, by which most kinds are carried over the winter. In some countries where the climate is equable and mild all the year many aphides continue to be viviparous from year to year.

The eggs of most aphides are difficult to detect because they

are flat, and generally exactly the colour of the trunk, shoot, or twig upon which they are laid. Those that have been recognised are observed to be large for the size of the insects. Sometimes they occur in twos and threes, at others in groups of fifty or a hundred.

Sometimes they are placed upon the leaf or flower-buds; for example, we may see them upon the leaf-buds of the Rose, when they are enlarging in February or March, looking like very tiny grains of gunpowder. It is probable that some seasons these eggs hatch out earlier than is generally supposed, and hence the importance of well cleaning, by the syringe and other means, all shrubs or trees which have been infested with aphides before a new brood can appear. We should, however, make a great mistake if we supposed aphides are entirely quiescent through the winter, because that is the season when eggs are found. There are plenty of them lively and active in various places, not only feeding at intervals, but engaged in the work of continuing the species, the females producing living young, wingless like themselves. When bedding plants and other tender exotics, which have been out of doors during the summer, are carried into houses for the cold season, some aphides are sure almost to accompany them, and the warmth favours the increase of the insects. Aphides also live through the winter under fragments of loose bark, and certainly upon several of our common evergreens. A. Rumieis has been found plentifully upon the Ivy at that season, but whether they really succeed in obtaining the sap from its uninviting leaves is uncertain. It is possible aphides can endure a fast, and that from evergreens they migrate to the early growth of fresh leaves along the banks and lanes. But the necessity of attending to plants in houses is shown by the tendency *Aphis opima*, a large green kind, stained with darker green, has to multiply when it can have warmth and moderate moisture. It haunts several favourite plants, but specially the *Cineraria*, and does much harm, as it not only exhausts the plants, but seems to exert some poisonous influence upon them. Again, there are aphides that through the winter hide underground, feeding upon the roots of plants, just as the too-well-known *Pemphigus Laetueae* occurs upon the Lettuce in summer. And possibly some of the aphides of our fruit trees, when their branches are bare, retire to their roots, or to those of humbler plants close by. All our recent observations upon aphid life indicate how very important it is to give such encouragement as we can to their many enemies of the insect race, which keep down their numbers far more effectually than we can with our best efforts. Thus the *Coccinellæ*, or ladybirds, are busily engaged, both as beetles and larvæ, from spring to autumn, each slaying its hundreds of aphides, and through the winter they are lurking in nooks and crannies ready for the first appearance of their prey; and it is one objection to some of our modes of aphid slaughter that we kill friends with foes.—
ENTOMOLOGIST.

EVENTS OF THE WEEK.—After the bustle and excitement of the recent exhibitions Chrysanthemum growers and exhibitors will have enjoyed a period of well-earned rest, and this (Thursday) evening the occasion of the National Chrysanthemum Society's dinner will afford them an opportunity of discussing the incidents of the past season. The dinner will take place at Anderson's Hotel, Fleet Street, London, and is to commence at 6 P.M. The events of the week as regards meetings and sales are few. To-day (13th December) there will be a sale of Orchids and Lilliums at Stevens' Rooms, King Street, Covent Garden, and of Dutch bulbs at Protheroe & Morris's Rooms, Cheapside. The following day there will be a sale of Orchids at the latter establishment, and of Lilliums, Dutch bulbs, Roses, &c., at Smalls' Rooms. On the 15th there will be a sale of Dutch bulbs at Stevens' Rooms.

THE WEATHER IN LONDON.—The present week has been much colder than the two or three preceding it. There have been heavy rime frosts from 10° to 15° being registered in the suburbs. A dense fog enveloped the metropolis on Monday and part of Tuesday, but has disappeared.

GARDENERS' ORPHAN FUND.—We understand that Mr. A. J. Brown, Hon. local Secretary for Sussex of the above Fund, is staying for a short time in Wensleydale, and with the co-operation of Mr. Hall,

gardener to Lord Bolton, making an effort to hold an entertainment in Redmire Town Hall in aid of the Fund. Gardeners in the district are invited to assist. The date will be shortly announced.

— **MESSRS. FOSTER & PEARSON**, Beeston, send us an **OFFICE ALMANACK** in twelve sheets, for the different months, and ask us to say that any gardener is welcome to a copy who may not have received one. It is useful for suspending as a reminder of dates, and contains postal and other information.

— **MESSRS. J. WEEKS & CO.**, Chelsea, remind us of the coming year by a sample of their **HORTICULTURAL POCKET BOOK AND DIARY FOR 1889**, which they distribute amongst gardeners. It is in a solid leather case, and is strong, convenient, and useful, containing pockets for money and stamps, which we hope will be well furnished; blank pages for notes that may be instructively occupied; and tables of information to which possessors may turn when their memories fail them.

— **MILD WEATHER AND SLUGS.**—"A Lanarkshire Bee-keeper" writes:—"The warm weather has been very favourable for destroying slugs and snails, as they were all on the surface and easily dispatched with a little quicklime. Underneath heaps of rubbish left for the purpose many were congregated, a slight dusting of lime quickly preventing their doing further injury to plants and flowers."

— **THE COMMITTEE OF THE CHORLEY CHRYSANTHEMUM SOCIETY** have fixed the date of their sixth annual Show of Chrysanthemums for November 22nd and 23rd, 1889.

— **AT THE ORDINARY MEETING OF THE ROYAL METEOROLOGICAL SOCIETY** to be held at 25, Great George Street, Westminster, on Wednesday, the 19th instant, at 7 P.M., the following papers will be read:—"Note on the Prolonged Spell of Cold Weather from September, 1887, to October, 1888," by Charles Harding, F.R.Met.Soc.; "Report on the Phenological Observations for 1888," by the Rev. T. A. Preston, M.A., F.R.Met.Soc.; "A Winter's Weather at Massowah," by Capt. D. Wilson-Barker, F.R.Met.Soc.

— **A CORRESPONDENT** writes:—"The members of the **LIVERPOOL HORTICULTURAL ASSOCIATION** met for their annual dinner on Saturday, December 8th. There were about 140 members present, and Stanley Rogerson, Esq., Hon. Treasurer of the Society, occupied the chair. The meeting proved a very pleasant one. Mr. R. W. Ker replied to the toast, 'The Horticultural Trade,' and Mr. Bardney and Mr. Powell, Botanic Garden, for 'The Press.' Mr. White, the Chairman of the Society, replied to the toast, 'The Liverpool Horticultural Society.'"

— **WE** have received from Messrs. Wood & Son what they modestly call their **NOTE BOOK**. It must not be understood as filled with blank pages on which notes can be written from time to time, but on the contrary about ninety pages are crowded with printed cultural notes on various subjects, by men whose long and successful experience entitle them to be regarded as sound advisers. The subjects appear to have been well selected, and are generally ably treated, but a few faults are apparent in editing; these, however, not in the least affecting the usefulness of the pages.

— **GARDENING APPOINTMENTS.**—Mr. C. Dawson, lately foreman at Ewenny Priory, Bridgend, has been engaged as gardener to Mrs. Saunders Davies, Cilwendeg Park, Boncath, Pembrokeshire, South Wales. Mr. W. Hunt, for the past five years outside foreman at Swanmore Park, Bishop's Waltham, has been appointed to the charge of the garden of the Rev. H. E. Trotter, Ardington Vicarage, Wantage, Berks. Mr. E. White, for fourteen years gardener to Mr. Soames, Cranford Hall, Kettering, after an absence of twelve months at Rock House, Derby, has been reappointed gardener at Cranford Hall, under a new employer.

— **TULIPS AT THE PARIS EXHIBITION, 1889.**—We are informed that Messrs. E. H. Krelage & Son of Haarlem, Holland, have planted in the Horticultural Park of the Paris Exhibition of next year six beds each of 225 square feet superficial with late Tulips selected from their new collection of breeders, consisting of upwards of seven hundred varieties. Messrs. Krelage are the first of foreign exhibitors whose installation is established. The Tulips have received a prominent position, as the beds are formed in the large grass plot in front of the Palace of the Trocadero. These Tulips, flowering usually about the middle of May, are expected to be ready at the opening of the Exhibition, or shortly afterwards.

— WE regret to learn the somewhat sudden death on Monday last of Mr. ROBERT CASTLE of Merton, Surrey, at the age of seventy years. Mr. R. Castle was respected by all who knew him as an earnest well informed gardener of the old school. He commenced his career about 1830 with his father, who then had charge of Mr. Swainson's garden at Cross Deep, Twickenham, an establishment noted at that time for its large collection of hardy plants and shrubs, and which is repeatedly mentioned in "Loudon's Magazine" as "The Twickenham Botanic Garden." Since then Mr. R. Castle has had a varied and extensive practice in private gardens and nurseries in the South of England, his last charge being Orsett Hall, Romford, Essex, which he left at the death of the proprietor, four years ago. He had a wide practical knowledge of and a deep interest in horticulture; he has also been a constant reader and an occasional contributor to this Journal, on the staff of which his son, Mr. Lewis Castle, has been for several years engaged.

— A WELL attended and representative meeting of gardeners took place at the Lodge Hotel, Reading, on Thursday, December 6th, for the purpose of forming a GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION FOR READING AND DISTRICT. Mr. Jas. Pound, jun., presided. Letters were read from Messrs. Coombes, Tegg, Wildsmith, and others expressing sympathy with the movement, and their readiness to do all in their power to promote its prosperity. The following officers were elected:—Mr. W. Lees, Chairman; Mr. Turton, Vice-Chairman; Mr. Woolford, Treasurer; Mr. Jas. Pound, jun., Secretary; and Messrs. Tegg, Coates, Stone, Balchin, Fry, Hawkins, Hall, Castle, House, Cloke, Bennett, Butcher, and Hinton.

— SPRING FLOWERS IN DECEMBER.—At a meeting of the Royal Botanic Society, held on Saturday, Mr. J. P. Gassiot, Vice-President, in the chair, there was shown specimens of twenty-four different kinds of spring flowering plants which had bloomed in the open air in the gardens of this Society, and gathered on December 8th. Mr. R. Dean sends us a number of flowers of coloured Primroses gathered from plants in the open ground on Friday last. They are as bright and fine as we usually see them in April. A Gravesend correspondent, whose name we cannot decipher, sends us a flower of the common field Poppy gathered on Sunday last.

— RAINFALL AT DORCHESTER.—Mr. John Campbell, Mickleover Manor, Derby, writes:—"Has not Mr. Chapple (*vide* page 517) made a mistake in his measurement of rainfall for November—viz., 10.28? The average would be about 3.00 according to the published report of G. J. Symons, Esq. Or has a waterspout fallen over the rain gauge at Cattistock Lodge from the heavens, or by human aid?"

— RAINFALL FOR NOVEMBER.—Mr. N. F. Fuller writes from Horndean:—"I think it would be better if observers of rainfall would state diameter of rain gauge when sending in reports. If Mr. A. Chapple's gauge is 8 inches in diameter, it would probably account for his measurement. We recorded 5.73 inches for November with a 5-inch gauge."

— HEAVY RAINFALL.—Mr. G. J. Symons, F.R.S., of 62, Camden Square, N.W., writes:—"Your correspondent, Mr. Chapple, will probably have to live a good while at Cattistock before he again records 10.28 inches of rain in November, the amount being probably not far from double the fall usual there in that month. The rainfall varies so much in different parts of the country that to give the average fall for November accurately would take several pages of the Journal, and I am sure that the Editor would protest. Roughly, the average for November in England and Wales may be said to be between 2½ and 4 inches at all places not in or among hill districts; in such localities the average runs up 6 or 7, and at Seathwaite to nearly 12 inches. Mr. Chapple, and I hope some other of your readers, will be interested in the following totals for November; all of them larger than his. (N.B.—I hope no one will try to get either very large or very small values; we want the truth, and nothing but the truth, and have now very good opportunities for detecting any falsification or practical jokes). Nantgwillt, Rhayader, Radnor, 11.01; Arncliffe, Skipton, Yorks, 11.05; Holne, Ashburton, Devon, 14.74; Seathwaite, Keswick, Cumberland, 22.87. May I add that I am on the point of issuing gratuitously blank forms to every observer known to me, and that I shall be very glad of a line from anyone who is keeping, or is about to keep, an accurate record, that I may help him (or her), and he (or she) may help me."

— THE "Botanical Magazine" for December contains coloured plates of the following plants:—*BEGONIA SCHARFFI*, a South Brazilian plant introduced by Messrs. Haage & Schmidt from the Peninsula of

Destierro in the Island of St. Catherine, and was sent to Kew, where "it flowered in September, 1887, producing female flowers, followed in October by male flowers and female buds, and in November by another crop of male flowers." It is regarded as nearly related to *Begoniastrum Schmidiana*, and is one of the finest members of the genus. The leaves are a foot or more in length, bright green on the upper surface and reddish below; the flowers are large, freely produced, white, with a few rosy hairs on the outer surface, the peduncles being of a similar colour.

— THE plate of *IRIS SUWAROWI* (T. 7029 in the same work) represents a curiously coloured species from Central Asia more distinct than beautiful. It was found by Dr. Albert Regel in Turkestan in 1885, flowered at Baden Baden in 1886, and at Kew and Cambridge in May, 1888. The standards and falls are veined with dull reddish purple on a greenish ground, the falls have a lilac-blue beard.

— IN T. 7030 is given a figure of *PENTAPERA SICULA*, a pretty Ericaceous shrub from Sicily, Cyprus, and Cyrenaica. In general habit, foliage and flowers the plant is very Heath-like, the small bell-like flowers being borne in drooping clusters at the point of the branches, white with a pink calyx.

— THE curious little Columbian Orchid, *Hexisia bidentata* (T. 7031) is described in another column, but *PRIMULA RUSBYI* (shown in T. 7032) merits a note here. It is a species from New Mexico, one of the few species natives of North America, of which the following are named:—*P. nivalis*, *P. cuneifolia*, *P. borealis*, *P. egalikensis*, *P. mistassinica*, *P. farinosa*, *P. angustifolia*, *P. suffrutescens*, and *P. Parryi*. *P. Rusbyi* was found in the Mogollen Mountains of New Mexico by the traveller whose name it bears, and subsequently by Pringle. The leaves are long and narrow with a crenulated margin. The flowers are of moderate size, bright rosy purple, in loose but graceful heads. The colour is a particularly pleasing one.

— A DAILY paper of December 6th gave the following on the MILD WEATHER that distinguished the past week:—"A strong and broad, current of air continues to sweep across our islands from the equatorial regions of the Atlantic, and unusually mild weather is reported over the entire kingdom. On the continent, however, where light breezes descend from a large anticyclonic system lying over Central Europe, conditions are more seasonable, and as a result some curious contrasts have recently been observed between the weather over England and the state of things prevailing in localities which bear a reputation for sunny geniality. On Tuesday morning, for example, London was 5° warmer than Naples, 7° warmer than Monaco, 9° warmer than Laghouat, in Central Algeria, 11° degrees warmer than Constantinople, 12° warmer than Bordeaux, 14° warmer than Marseilles, 16° warmer than Rome, 17° warmer than Madrid, and 19° warmer than Paris. Yesterday morning very similar contrasts were observed, the weather in the metropolis being 3° warmer than Lisbon, 11° warmer than Nice, 19° warmer than Paris, and 30° warmer than Belfort. Even in the north of Sweden, where the south-westerly current of air has exerted some slight influence, the weather yesterday was much milder than it was over the central parts of Germany and France, Haparanda being no less than 12° warmer than either Lyons or Munich. In the course of the day the thermometer in London reached a maximum of 58°, and yesterday was therefore the mildest December day experienced since 1873, when a similar reading was recorded on the 17th of the month. An examination of the meteorological statistics shows that the thermometer in December seldom rises above 55°, and in the years 1885, 1886, and 1887 it did not succeed even in reaching that level. The warmest December day on record was in the year 1848, when the thermometer at the Greenwich Observatory rose to 62° on the 10th. The reports of last evening gave no indication of any divided change in the weather. The Continental anticyclone remained firmly established, and fresh breezes from the southward or south-westward continued to blow over the whole of the United Kingdom. The 6 P.M. temperatures were above 50° in most places, and at Shields and York the thermometer stands as high as 57°." To this we may add a change occurred on Sunday night last, the 9th inst., slight frost being apparent on Monday morning."

SINGLE ANEMONES.

For insuring a supply of the beautiful Poppy Anemones in spring, than which few flowers are more attractive in beds and borders, or more suitable for the ornamentation of vases, tubers should be planted with as little delay as possible. They are very cheap, and a good display of flowers may be had for a small investment. Should the planting be

unavoidably delayed, the bed must then be covered with fern or straw. Choose a time when the soil is moderately dry, and the day fine. Draw drills across the bed 2 inches deep and 5 or

placed the right side up, by observing the side that has the old small fibres on it. That side placed next to the bottom of the drill. When all are planted and covered the right depth (2 inches), then level the

FIG. 59.—SINGLE ANEMONES.

6 inches apart, and plant the tubers 4 inches apart in the rows. A thin layer of sand scattered under and around each tuber will be useful. As soon as the bed is planted, cover the tubers with sandy loam from a basket or wheelbarrow. Take care that the tubers are

surface with a garden rake. If the plants have any kind of covering and the weather prove mild, the covering should be removed, and replaced on the likelihood of a return of frost, and when the spring sets in remove the shelter entirely.

LÆLIA VICTORIA.

At the meeting of the Royal Horticultural Society's Floral Committee at the Drill Hall, Westminster, on November 13th last, Baron Schröder, The Dell, Egham (gardener, Mr. Ballantine), showed a specimen of this exceptionally handsome and interesting

L. elegans. It is similar in habit to *Cattleya Mossiae*, having short fusiform one-leaved pseudo-bulbs, but the leaves are longer, more in the way of *L. elegans*. The flowers are as large as those of that species, and splendidly coloured; the sepals and petals are bright rosy purple, with darker reticulations, and are similar in shape and size to those of *C. Dowiana*, while the lip is of an intense and beautiful deep blood purple, the rich dark colour being carried to the margin, and the tube only showing a little of the golden venation of *C. Dowiana*. It is to be regretted that this plant, through being a hybrid, must always be scarce, as its great beauty and distinctness claim for it the premier position among the dark-flowered *Lælias*. It flowers in August."

Lælia Victoria presents an interesting combination of the characters of the two Orchids above described. The petals are

FIG. 60.—LÆLIA VICTORIA.

hybrid Orchid, and from one of the flowers our illustration (fig. 60) was prepared. This plant resulted from a cross between *Cattleya crispa* and *Lælia Dominiana*, the latter being itself a hybrid. Mr. B. S. Williams thus describes the parents named:—

"*C. CRISPA*.—A splendid free-growing Orchid with one-leaved sub-cylindrical angulate stems about 1½ foot high, flowering in July, August, and September; the flowers have the sepals and petals bluish white, and the lip white, with a rich crimson stain on the front lobe. A single spike frequently produces four or five flowers, which continue in perfection for two or three weeks. This is a fine plant for exhibition in July and August. The colour of the flower is remarkably attractive, and it always produces a good effect in a collection."

"*L. DOMINIANA*.—This glorious hybrid was raised in Messrs. Veitch's nursery by Mr. Dominy, and is the result of a cross between *Cattleya Dowiana* and a species of *Lælia*, probably

much undulated and folded after the style of *Cattleya crispa*, the sepals being recurved and also suggestive of the same parent. The lip is particularly beautiful, of an intensely rich rosy crimson or purple tint, narrowly margined with white. The flowers are also very fragrant, and altogether the hybrid possesses ample to recommend it to notice, though it is likely to be scarce for some time to come.

HEXISIA BIDENTATA.

THE "Botanical Magazine" for December contains a coloured figure and description of this curious little Orchid, from which we extract the following:—*Hexisia*, or as it was originally, probably by inadvertence, spelt *Hexisca*, is a small genus of Mexican, Central American, and tropical South American Orchids, of which one species only had previously been figured, the *H. imbricata*, *Reichb. f.*, (as *Diothonea imbricata*) in Lindley's "Sertum Orchidearum," t. 40, f. 1; a native of Roraima in Guiana. The genus was first

described as having a closed perianth; an error corrected in the "*Genera Plantarum*," where, however, the lip is described as erect.

H. bidentata was discovered by Cuming in Western Colombia and Panama, and subsequently found by Grsted in Nicaragua. The plant was procured for F. A. Philbrick, Esq., Q.C., in 1887, and flowered in the Royal Gardens in June of the present year.

DESCRIPTION.—Stem tufted, 6 to 8 inches high, stout, branched, formed of fusiform many-grooved internodes 1 to 2 inches long, clothed when young with appressed subacute sheaths. Leaves in pairs in the terminal internodes, coriaceous, 2 to 4 inches long by a quarter of an inch broad, spreading, linear, obtusely two-fid at the apex, channelled above, keeled beneath, dark green. Flowers in shortly pedicelled few-flowered racemes from between the leaves; pedicels half an inch long, clothed with ovate-acute sheaths; bracts lanceolate, shorter than the pedicels, which are about half an inch long. Flowers sub-erect; lip anticoncave. Perianth an inch in diameter, spreading, scarlet. Sepals ovate-oblong, obtuse. Petals rather smaller. Lip about as long as the sepals, linear-oblong, sharply deflexed from the claw, which is adnate to the face of the column, sides straight, apex obtusely triangular, disk smooth, base fleshy. Column short, side lobes reaching a little above the level of the anther, oblong, obtuse, obtusely two-toothed on the anterior margin. Anther four-celled, depressed; pollinia four, sub-globose, with slender stalks that are attached to a viscous mass.

FACTS ABOUT PEARS.

As a rule the crops of Pears were comparatively light, and the size of the fruit was also below the average. Owing to the small amount of sunshine we were favoured with this year, many, doubtless, anticipated a late period of ripening, and it was also thought the quality of numerous varieties would be very inferior; but in addition to Pears ripening very much in due course, the quality is surprisingly good, in fact it was never better as far as my experience goes. Frequently the smaller fruits are uneatable, or, at any rate, of very poor quality, but this season all are alike good, quite the smallest being juicy and sweet, or very much as the larger fruit are found to be. From this it would appear that we are very apt to form erroneous opinions as to the necessity of so much solar heat for this class of fruit, though it may be much more of it is necessary for the thorough ripening of the wood than we had this year. Much the finest Pears are grown on the Channel Islands and in France, but fine as these are they are rarely so good in quality as the comparatively small fruit grown in this country, and this is another confirmation of my theory that, as a rule, Pear trees do not generally get nearly enough moisture at the roots. During a hot summer or in dry hot positions the fruits attain their greatest size, but only those well developed are of good quality, the smaller produce being sour and dry. Those wonderful Chaumontels grown in Jersey, and largely distributed throughout this country are rarely fit to eat. They form a showy dish on the dining table, but of the dozens I have tasted not one has been fit to eat till the cook has taken them in hand, yet we have had quite small Chaumontels of fairly good quality and comparatively small. Doyenné du Comice and Glou Morceau ripened in this district have proved superior in quality to very fine samples imported. On the whole, therefore, it is very evident we may easily overrate the value as far as quality is concerned of extra fine fruit.

A certain amount of heat no doubt is necessary to aid in the maturation of the crops, but, as I have tried to demonstrate, lack of quality is more often due to poverty at the roots than a deficiency of sunshine. All the while the trees produce plenty of fairly strong lateral growth, many cultivators rest contented and do not think of applying either solid or liquid manure, or even clear water till there are signs of a collapse. Much restricted trees may form abundance of growth and yet stand in great need of assistance at the roots. If better treated in this respect the trees would, providing frosts did not prevent it, produce annual rather than biennial or triennial crops of fruit. Not only are the trees unduly weakened by the production of a fairly heavy crop of fruit, and thereby rendered incapable of performing the same functions in the next season, but much of the fruit obtained is also of second rate quality. In the garden under my charge there is a long sunny wall well furnished by a great variety of cordon trained Pear trees. When I first undertook their management it was thought that many of the varieties were quite worthless, as not more than a dozen out of the fifty varieties grown ever produced fruit fit to eat. All the trees were imported from France, and it was supposed the majority of them required more heat to bring them to perfection than our uncertain climate affords. An experienced fruit grower with whom I talked over the matter suggested that, as the trees must not be either rooted out or re-grafted, the best thing that could be done

was to give the roots good solid manure. About this time of the year they were lightly bared to a distance of 4 feet from the wall, a thick dressing of partially decayed farmyard manure being then disposed over them, and the surface soil returned to its old position. A marked improvement was manifested in the weight and quality of the crops in the following season, and this was maintained for several summers after. A repetition of this treatment in the early part of December, 1886, has served to sustain this improvement. If we fail to obtain a good crop every season it is not now the trees' fault, as most of them annually form plenty of fruit buds, and the failures are due either to the depredations of birds or the effects of frost.

Well-established fruit trees rarely get so much manure as they really stand in need of. In many instances they are planted in rich loamy soil, and while this retains a portion of its fertility the crops are usually satisfactory. Vegetables, on the contrary, are frequently treated to more manure than is good for them, and if the fruit trees are rooting near they receive the benefit accordingly of what was not intended for them. Instead, therefore, of poisoning the ground with so much manure, which only results in the production of rank, strongly flavoured crops, it would be much more to the purpose if some of the manure was applied to the fruit trees. Those which stand in the greatest need of manure are the wall trees or raised or much-exposed borders. No crops ought to be grown closer than 3 feet from the walls, and it would be very much better for the trees if they were allowed at least another foot of clear undisturbed root-run. In any case all should receive an occasional surfacing of solid manure applied just below the surface rather than being either forked in or laid on the surface where much of its fertility would be wasted; and well-established trees pay for the application of liberal supplies of liquid manure both during the winter and when the roots are active. A good food supply, coupled with abundance of moisture, keeps the roots near the surface, encourages productiveness, and insures the formation of valuable crops of fruit. It does not follow that because I recommend this treatment for trees in full bearing that it is also good for vigorous young specimens. These sometimes require cheeking at the roots in order to cause fruitfulness, but it is not wise to wait till they become stunted (a by no means rare occurrence in the case of severely root-pruned trees) before applying the manure. If solid manure is scarce plenty of leaf soil will be found a good substitute.—W. IGGULDEN.

CHRYSANTHEMUM BLOOMS DAMPING.

I FEEL I may say a few words in regard to this subject—viz., Chrysanthemum blooms damping. In the first place, I fully agree with your correspondent, Mr. Hopkins, that over-feeding is the cause of the trouble to a great extent, although I am fully of opinion that the atmosphere has something to do with it. I grew about 300 plants this season, and disbudded to four blooms on a plant, which I may say were very strong and healthy, and was looking forward to having about 1000 good flowers entirely for exhibition purposes. All went well till they were about three parts expanded, and feeding discontinued, when, on examining the plants one morning, I was grieved to see about half a dozen blooms of the Queen family—notably Lord Alcester and Golden Empress—which were about three parts unfolded, covered with a quantity of little brown spots, as Mr. Molyneux styles it in his valuable treatise, resembling dust. I immediately gave more ventilation, thinking there might be a lack of it, and also warned the pipes. Next morning I was still further grieved to see quite half the blooms affected with the same complaint, and a day or so after nearly every plant more or less was on a fair way to destruction. Suffice it to say that out of my 1000 blooms as expected I only cut about 200 really worth anything. The principal manure the plants were fed with was sheep's dung, with an occasional dose or two of sulphate of ammonia, about twice a week during October. I may say that about half a dozen of the plants were hardly fed at all, and with them damping was not the least visible, nor was it with about 50 plants which were not disbudded, and which were merely fed with sheep manure three or four times during the season. This season, as all Chrysanthemum growers will agree, has been a deplorable one for the "Queen of Autumn" flowers, and I am firmly persuaded the continual wet weather had a great deal to do with damping, the overcharged sappy stems never being fairly ripened. In conclusion, I will just say that as regards sulphate of ammonia, I intend to have very little to do with it in the future, believing it to be a very dangerous and damp-causing manure. Hoping to hear further correspondence on this subject.—C. SIMPSON.

EARLY CHRYSANTHEMUMS.

REFERRING to the article on early Chrysanthemums by Mr. W. Piercy at page 490, I think it is time some more definite method of classing these should be found, and perhaps Mr. Piercy might be induced to classify the sorts, particularly as to the period they come into flower in the open borders. I do not suppose I am singular in my experience with regard to these, which is one of much disappointment that many early sorts flower so late as to require the protection of glass in our northern climate. Those that do flower are among the finest border flowers—*e.g.*, *Précocité*, which begins flowering in July; *Madame Desgrange* and varieties, which begin six weeks later, beside several *Pompons* that are pretty but of less value. Flowers which do not come in until October are too late for borders. *La Vierge*, for instance, is a most useful variety, but it has to be flowered under glass; *Roi des Précoces* belongs to the same class. Of those named by Mr. Piercy I do not know *Grace Attick*, but will try it another season. *Sam Henshaw* has the unfortunate fault of flimsiness and an open eye, and will not do in the north. *Elsie* is going to prove a good decorative variety, but it only opened its flowers in the beginning of December. *Madame C. Souchet* is about the same stage as the above.

Some other varieties of the present season, which I like better and are a month earlier, are—*Capucine*, a very pretty dwarf grower; *Madame Jonis Langlois*, the earliest to open, of a very pretty shade of rosy violet, dwarf and good; *Bettina*, clear orange, edged with yellow, I expect will prove a standard decorative sort; *Madame Mezard* is very distinct, the florets, which are a light violet, are sprinkled over with white blotches; *La Tosca* is a dark crimson; *Condor*, white, worth trying. Several other kinds, all of which were selected from the catalogues as early, have not yet flowered.

The present has been a disappointing season, so many sorts having failed to flower, and among these some of the most useful. *Elaine*, for instance, is generally a failure; *Mdlle. Lacroix* is flowering very sparsely; *Source d'Or*, *Ornements*, *Lady Selborne*, *Simon Delaux*, and many others showing scarcely a flower. Of those that have done well are the *Rundle* family; *Queen of England* and its varieties; *Mons. W. Holmes*, a grand sort; *Reverie*, very good; *Chevalier Domage*, *Sœur Melanie*, *Mrs. Forsyth*, *Fair Maid of Guernsey*, *Julie Lagravère*, *Peter the Great*, and *Princess of Teck*.

I omitted to say that I have heard very good accounts of a new variety of this year named *Margarita*, in the way of *Elise Dordan*, but which flowers throughout the summer and is very sweet scented.—B.

CHRYSANTHEMUM STAKES.

WHETHER Chrysanthemums are grown for exhibition or home decoration, they generally require stakes, and this fact is often overlooked until they are required, which happens at a very busy time. Where wood stakes are used they are generally in readiness, but where hedgerow sticks are used it is often the reverse. I wish to remind those in charge that any time during the winter is the best time to get them. Now, while the hedges and trees are leafless, it is easy to see which are the straightest and best for the purpose. They can also be used much thinner if cut now than when they are full of sap, as they will not bend about like fresh-cut ones. If tied tight together in bundles they will dry straight. The time can be better spared now than in June or July, when so many things require attention. In visiting several gardens, I have been impressed by this want of timely consideration by noticing stakes used as thick as walking sticks where as thick as lead pencils (near the top) would have been sufficient, and this is important when the plants are required for conservatory decoration.—E.

NEW AMERICAN CHRYSANTHEMUM.

A SHORT time since one of our leading nurserymen sent me a bloom of a Japanese Chrysanthemum which had created much sensation in America this season. I was asked to give an opinion as to its merits. From the note on the same subject on page 514, I think the two are identical, or nearly so. I could not discern any difference between the bloom I saw and *Mrs. H. Cannell*. The flower in question was a bad one, but it was of the character of the Japanese variety named. The only difference I could see was that the back of the petals were more thickly covered with the long silky hair mentioned in the report from the *American Florist* than in the case of the blooms of *Mrs. Cannell*, though these have small hair-like particles on the reverse of the florets, these showing a decided tendency to incurve in the same manner as those of the variety named. From the bloom I saw, I was bound to say that not sufficient difference existed between the two varieties to warrant me in saying they were distinct.—E. M.

A WALL OF CHRYSANTHEMUMS.

BY this I mean a wall 84 feet long and 10 feet high, the back wall of a spacious lean-to Peach house, a mass of flowers from near the bottom to the top, and no break showing the bare wall. This is to be seen year after year at *Berry Hall*, *Solihull*, near *Birmingham*, the residence of *Joseph Gillett, Esq.*, of steel pen fame, and it is "a sight" worth seeing. The sorts planted are *Curiosity*, *Jardin des Plantes*, *Gloire de France*, *Peter the Great*, *Flambeau*, *Belle Paulc*, *Fleur de Marie*, *Baronne de Prailly*, *Thunberg*, *Cry Kang*, *The Cossack*, *Elaine*, *Crimson Velvet*, of a lovely bright glossy colour; *John Salter*, *Illustration*, *James Salter*, *Jane Salter*, *Fair Maid of Guernsey*, *Rubra Striata*, *Dr. Maeary*, *Bronze Jardin des Plantes*, *Madame de Sevin*, *Duchess of Albany*, *Mme. B. Rendatler*, *Mrs. Bunn*, and *Comte de Germiny*. These

are established plants planted in the border against the back wall, close to which a wood trellis part way is placed, but the roots are away into the Peach tree border of the house. In training the plants very little is cut away, as a mass of flowers is the chief object for cutting from. These plants are cut back in January, never stopped, and almost every growth tied in. When armfuls of cut flowers are wanted and Peach house or other walls are at disposal, that is a very easy method of securing them, independent of producing a charming display.

Mr. Milton, the gardener here (the family of *Miltons* are well known in connection with Mr. Maurice Young's nursery at *Godalming*), grows a good collection of Chrysanthemums independent of those on the wall, and amongst other newly introduced varieties the following are in fine character with him—*viz.*, *Madame John Laing*, *Mrs. J. Wright*, *Mdlle. Blanche Pigny*, *Mawet Postula*, *Pelican*, and *Lady Lawrence*, a large white, resembling *Pelican*. Peaches are grown extensively at *Berry Hall* in spacious well-built houses, each 84 feet long.

Berry Hall also has a celebrity for *Conifere*, a fine collection having been planted many years ago, including several of the rarer species so little planted now. There are fine specimens of *Abies invecta* (the *Drooping Spruce*) planted thirty years ago; a fine *Picea grandis*, 20 feet high; a grand *Abies monstrosa*, and a *Picea magnifica*, 15 feet high; and a host of others. An excellent collection of herbaceous plants, including the leading varieties of the *Pæonies*, are grown here.—D.

M. A. DE LEAU.

THE variety I exhibited both at *Birmingham* and *Pontefract* under the name of *Albert de Leau*, should have been named *M. A. de Leau*. I was also under the impression that it was the *Albert Deleau* of the N.C.S. The variety in question I had from Messrs. W. Clithran & Son, *Altrincham*, and am indebted to that firm for the correction. I submit *Deleau's* description—"M. A. de Leau (*Deleau*), pure white, as white as that beautiful variety *Hélène*, but splendid blooms, no empty space, and double the size of flower. It is without doubt the finest white variety ever seen." I consider it quite distinct from *Elaine*, having more the form and petal of *Mons. Astorg*, with the pure white of *Avalanche*.—D. LINDSAY, *Otterspool Gardens, Liverpool*.

[Our correspondent is probably right, and his blooms were very fine, answering well to the description. The *Albert Deleau* of the N.C.S. Catalogue should, we suspect, be *Albert Delaux*.]

CHRYSANTHEMUM FABIAN DE MEDIANA.

WHEN reading about this Chrysanthemum in the last issue of the *Journal*, the first thing that struck me was that Mr. Machattie cannot have the true *Fabian de Mediana*, for he says this variety "has been shown in splendid condition in Scotland this season." When in good condition, *Fabian de Mediana* is acknowledged to be the best type of Japanese *Anemone* we have, being so full centred, the disc especially large, while the guard florets hang quite perpendicularly. The colour of these is deep lilac, the centre being bluish shaded purple. If your correspondent has the true *Fabian*, I am at a loss to know how it resembles *Duchess of Albany*, which is a full Japanese, without the least appearance of an *Anemone* centre. Has Mr. Machattie been misled with the bad form of the *Anemone* this season? I have not seen a really good bloom of it anywhere, but plenty which would give an idea that it was a Japanese variety by the entire absence of properly formed quill florets, which are needed to make a typical *Anemone*. But, then, I have not seen any blooms of *Fabian* which were at all like the *Duchess* in colour, of course assuming he alludes to *Jackson's* variety, that with the orange buff, shaded red florets, this being the variety which is so commonly called the *Duchess of Albany*. The other variety (*Veitch's* or *Salter's*, I forget which) is not much grown. This would more resemble the colour of *Fabian*, which, in the absence of the distinction which Mr. Machattie does not give, renders the matter more uncertain. Even should the latter be the variety to which Mr. Machattie alludes, there is a wide difference between it and *Fabian de Mediana*. The former has much broader florets, which fill up the centre, the points of which recurve.

My opinion is, that no bloom of *Fabian de Mediana*—no matter its form or otherwise—ought to be admitted into the Japanese section under any consideration, because if such a commencement is made, where will the line be drawn? It must, indeed, be a badly grown flower which does not, in some manner, display its true character; therefore, I would say, if it is not fit to be shown in its proper class it is not fit to be shown at all. Even if it were possible to obtain a bloom without any sign of *Anemone* character, I fancy it would not assist the Japanese section greatly. There are quite enough in the latter family without admitting *Anemone* varieties. I do not know what the rules are in Scotland regarding the admission of varieties such as *Triomphe du Nord* into the reflexed class, but I never but twice saw it staged in England in a reflexed stand, and then I was under the necessity of disqualifying them or of passing them, which was nearly the same thing. I do not believe in the fashion of allowing one sort to be shown in two stands which are supposed to be opposite in character. My idea is, give all a place and keep them there, and there only. If such method was practised strictly more satisfaction would be given, and exhibitors would know what varieties to depend upon for the different stands.—E. MOLYNEUX.

CHRYSANTHEMUMS AT SOLIHULL.

ONE of the most successful cultivators in Warwickshire is Mr. Thomas Hewitt, who retired from the nursery business a few years since, and

now devotes himself to amateur gardening, Chrysanthemums especially. He potted 600 specimen plants this year, but, like many others, a goodly number of his plants were out in that fatal October frost and were terribly punished. Still he has a fine display, growing all his plants on the single-stem plan, many of the flowers being as fine as they well can be. In looking over the collection since I noticed as very good Carew Underwood, La Vierge; a pretty sport from Mdlle. Lacroix; Fabian de Mediana, Madame J. Laing, very fine; Maiden's Blush, Madame Deville, M. Baco, M. Brunet, Marguerite Marrouh, Mdlle. Blanche Pigny, Mrs. J. Wright, President Garfield, Mabel Ward, Christmas Eve, Duchess of Albany, Val d'Andorre, E. Molyneux, Ralph Broekiebank; a sport from Meg Merrilies; Comtesse de Beauregard, Boule d'Or, Mr. Garnar, Florence Percy, a very fine thread-like form of great beauty; Criterion, M. Elliott, and other leading kinds.

Amongst the incurred kinds the following are very fine:—Golden Empress of India, Mr. Bunn, Lord Alcester, Mrs. Dixon, White Venus, and Jeanne d'Arc, Mr. Hewitt has a lovely bright lilac sport from Princess of Wales. Chrysanthemums are grown remarkably well, though Mr. Hewitt does not exhibit; but his collection is "a draw" for visitors. It will become a raised question, however, shortly whether very tall Chrysanthemums are desirable, and if this great height cannot be obviated and dwarfier plants with from three to more breaks with equally fine flowers cannot be grown and exhibited successfully.

My friend Mr. Hughes, Secretary of the Birmingham Chrysanthemum Society, saw at Sutton Coldfield a few days since a group of dwarf plants which were stopped, I think, in May or very early in June, grand in the size and quality of the flowers, and averaging from 3 to 3½ feet in height or so. He was so struck with their style and quality that he told me he should adopt this plan another season. A very large number of specimen single-stem Chrysanthemums are grown in this way. Mr. Comfort, gardener at Knowle Hall, near here, grows 500 plants—and he does grow them too; but in many cases the plants have attained to a great height this year.—D., *Solihull*.

EXHIBITORS AND THE LATE SHOW AT SHEFFIELD.

OWING to the lamentable want of competition in many of the classes at Sheffield reflections have been cast upon northern and southern exhibitors, which, to say the least, are not very complimentary. In reporting the Show the Horticultural Press commented strongly upon the presence of "fear" and the absence of "pluck" on the part of exhibitors. This has since been emphasised by Mr. W. Holmes at the recent meeting of the National Chrysanthemum Society. The *Journal of Horticulture* in particular pointed to the absence of all Liverpool growers as somewhat remarkable, an observation which will be readily endorsed by those unacquainted with the circumstances in which Liverpool growers were placed. From a personal knowledge of the growers and exhibitors of this neighbourhood I am in a position to state that "fear" forms no part of their programme.

During the last Government expedition to the Arctic regions a comic paper, remarking upon the energy of our Scotch brethren, observed, "The first man Captain Nares might expect to find on reaching the North Pole would be Sandy McFarlane keeping a shanty." And although Liverpool growers can hardly be expected to take their blooms to those regions, they certainly are to be found occupying prominent positions on the prize lists of most of the principal shows in the north of England. Of course this fact makes it appear all the more strange that Liverpool was not represented in competition at Sheffield. Had the principal and truly liberal prize been given for the usual twenty-four incurred and twenty-four Japanese instead of the representative collection I have not the slightest doubt that Liverpool at least would have been represented. Anemone and reflexed varieties are but little appreciated in this district, and consequently comparatively little grown. In the collections of those well-known cultivators, Messrs. Mease, Tunnington, Lindsay, Jellico, Heany, Roberts, Edwards, Wilson, and others, I question if a single example of these two sections can be found. In some instances they are not cared for by employers, a point which it is obvious must not be overlooked. Personally, I consider Anemones amongst the most beautiful of all the Chrysanthemums, and might have competed myself for the cup at Sheffield had the requisite number of Japanese Anemones been sufficiently early.

There certainly were other open classes at Sheffield, but 80s. for thirty-six blooms and 60s. for twenty-four is not sufficient inducement to keep pace with the times, therefore lack of competition in those classes is not to be wondered at. Even Chrysanthemum exhibitors are but human, and when one sees a good opportunity of winning a £10 prize he will not sacrifice that for the possibility of winning one of the value of £4. Considering the importance of the first provincial Show of the N.C.S., and the keen interest it was calculated to excite, I am sure the prize schedule of that undertaking was perused by many with feelings of disappointment.—A. R. Cox.

CANKER IN FRUIT TREES.

I MUST thank Mr. Tonks for his criticism of my remarks on the above subject; but his present statements are general, mine were particular, and are not disproved by what he says. He remarks that he thinks I may be led astray if I rely on analysis of my soil as a guide in estimating the ingredients of manure required to supply its deficiencies. I do not absolutely rely on it, and I would point out that I said that my soil was deficient in soda according to analysis, and that I had found much

benefit resulting from an application of soda to Strawberries, the ash of which contains much soda, and I deduced from this that probably an application of it would be beneficial to Apples, which likewise contain a large proportion of soda, and so far I cannot see that I have erred. Mr. Tonks thinks that it is extremely improbable that the iron in my soil is a cause of canker, as the quantity shown in the analysis was not excessive. The analysis was of the top soil in which fruit trees as a rule do well, but underlying this at various depths is a thick layer of what is called here "red pin," and under this again is ragstone rock. It is this "red pin" that is injurious, and by placing all dung on the surface, I endeavour to keep the roots of my trees near the top. It is noticeable that trees planted in fields where the rock is nearer the surface, and the red layer is absent, do not canker although the ground is full of springs, and yet the same varieties canker where the red pin exists.

It must not be imagined that the soil in this neighbourhood is a bad soil for fruit trees, for it is well known to be one of the best and most fertile, yet the trees do well in proportion as the red element is absent, but where it is abundant some sorts will not keep healthy.

The more dung and such manures as furnish humus are applied in preference to others, the better for the trees, as I believe they dissolve the iron in the soil. Mr. Tonks thinks I need not have any fear of the acid in superphosphate producing injurious effects, but doubtless he is aware that I am not alone in this belief. I have had trial plots of superphosphate in conjunction with nitrate of soda and other nitrogenous manures and plots manured with various other manures, and have come to the conclusion that those manures are best for fruit trees which make humus, encourage worms, and do not make the ground hard and unkindly, but render the surface tender.—WALTER KRUSE.

[An excess of iron in the soil undoubtedly causes canker in Apple trees, and we have seen a young orchard of several acres ruined in consequence.]

GARDENERS' EDUCATION AND THEIR SOCIAL POSITION.

WHILE giving your correspondent, Mr. A. Bighter, every credit for good intentions in writing as he has done on this subject (page 332), I, at the same time, consider his remarks illogical, and his standard of the gardener's social position unjust and delusive. I never before heard or read of a gardener being called a menial servant, or as being only the equal of the scullery maid and stable helper. In all gardening establishments presided over by duly qualified men the gardener ranks in position next to the steward of the estate, which position, in recognition of his fitness and integrity, the gardener is not unfrequently called upon to fill. Mr. A. Bighter asks, "Why should the gardener socially be considered superior to the stable helper, or treated differently?" Why, indeed? The gardener is a man of responsibility, having the management of valuable collections of plants, fruit trees, &c., as well as the engaging and directing of a staff of men, the formation and planting of new gardens and ornamental grounds, erection of hothouses, and the works requiring forethought, skill, and good taste. I, however, agree with Mr. Bighter in saying that frequently the gardener's position is pecuniarily inferior to the coachman's, cook's, and butler's. In conclusion, I may say that there is not much chance of parents putting sons who have received a university education to learn gardening as a livelihood. As a proof of this, we find very few gardeners bringing up their sons to follow the same employment, they educate them for filling a better social position than that occupied by themselves. This is as it should be, as long as the object of the parent's ambition is within reasonable reach, and the son shows a liking and probable fitness for the position he is destined to fill. Still, the advice which, with the approach of the long winter evenings, is annually given in the *Journal of Horticulture* and other gardening papers to young gardeners to improve their education is sound and practical, because there is no disguising the fact that the well educated practitioner has an advantage over the imperfectly educated one.—H. W. W.

UNSEASONABLENESS OF THE SEASON. A RETROSPECT.

I WAS going to send to the *Journal of Horticulture* a long list of flowers in full healthy blossom in Herefordshire, varying from well-developed blossoms of the Pear to the humble Daisy, which is spangling on lawns in such profusion as to tempt the school children to thread Daisy chains. And then, too, the Chrysanthemums turned out last spring in any odd quarter like old horses to take their chance. Who have not had their vases filled with these charming flowers of a variety and distinctness one finds perhaps in no other flower but Queen Rosa, whose majesty, by-the-by, has been so long and grievously outraged by months of cold and wet weather that she has not recovered to hold as usual her second court this autumn.

My chief motive in writing is to ask if any of your readers, who like myself have passed the broadly defined epoch of middle age, happen to remember how nearly the weather of 1888 resembles that of 1860? I was leaving that year my first curacy, and so the period comes to be well fixed on my memory. Yes, well do I remember how the hay and corn harvests were interrupted, and more even than this year blighted and spoiled through not passing through the bright interval of June weather we have been blessed with this autumn. Just the present mild weather, abnormally high both as regards night and day temperature, was kept up in December 1860 until Christmas eve, when the severest frost of

modern times set in. Writing from memory I forget how many degrees below freezing, but as the question raised at the time quite a controversy among meteorologists I will let sleeping dogs lie. *Absit omen*, for the effects of that frost and previous open weather I never wish to see again, for vegetation with wood so unripened and full of sap stood no chance. Even the common Laurels were cut down to the ground line, Roses everywhere were destroyed. I had just before removing sold several hundreds of standard Roses—Manettis were indeed rare in those early days—to King's Acre Nurseries, and never realised a penny owing to Jack Frost claiming them all. I also remember George Paul *filis*, as he was then, surprising me the spring following by a remark he made (it would not in the least now), when I alluded to my loss, though I need not say he spoke in general terms, "A very good thing; it will weed out the rubbish which we can't." I will not prophesy because, as Brother Jonathan says, I do not know; but every prognostication leads, I believe, to the anticipation of unusually severe weather with, if not before, the new year, and if so, which God forbid, then there will be a "weeding out" with a vengeance.—HEREFORDSHIRE INCUMBENT.

DOLLOND'S IMPROVED THERMOMETER.

THE eminent firm of opticians of the above name have sent us a very useful boxwood thermometer for gardens. It is customary when reading thermometers below freezing for gardeners to count so many degrees of frost. This is arrived at by a little mental calculation. This thermometer assists the process, indeed almost obviates it, for a scale below the tube indicates the number of "degrees of frost" in addition to the ordinary figures that indicate the temperature in the usual

FIG. 6.—DOLLOND'S THERMOMETER.

way. The small figure shows the two scales, and the instruments (which are advertised) will probably become favourites with gardeners, as they are good and inexpensive.

FIRM AND NARROW VINE BORDERS.

WHEN I wrote on the subject of narrow Vine borders several weeks ago I did not anticipate such a free response to my observations. It may be remembered that my remarks were not the outcome of vague theoretical notions, but were founded on accomplished facts, and as the authors or founders of these facts were given, and as not one of them has questioned the accuracy of the narration, I feel myself on tolerably safe ground; and certainly my confidence in firm and narrow Vine borders has not been shaken by the very fair criticism that they have elicited.

I have no time for turning back to the several issues of the Journal which contain replies to my letter, so cannot refer in detail to the points raised. Nor is this necessary, for so far as can be remembered only two of them call for comment. One is the expression of a doubt as to the lasting qualities of narrow borders, and the other the possibility of the soil being made too firm for free penetration by the roots of Vines.

In respect to the quick exhaustion of narrow Vine borders that seems to be feared—I forget by whom, but that is immaterial, as it is not persons but principles with which we have to deal—I think I recorded an instance of a Vine planted in a narrow strip at the end of a house bearing more and better Grapes than any Vine of the same variety grown in the same house, but planted in a large and costly border in front of it, and I also either stated, or intended stating, that the productive Vine in the narrow border that cost nothing outlived two sets of Vines and two new and wide borders, for the making of which scores of tons of soil were carted from a distance of a mile at least, and the cost of which must have been very considerable. I have recently been to the garden referred to, and pointed out to the gardener now in charge the aperture in the woodwork through which the Vine was introduced that gave such a good return, and which was planted in the natural soil in a strip not 2 feet wide between the house and the path. As may be expected he was a little interested when he found he was on the "spot" that he had seen referred to in the Journal, but not precisely indicated. And why not? may be asked. Well, because of an indisposition to reflect on a previous gardener who had incurred the cost involved in making two new deep and wide borders, and yet failed in producing anything approaching such Grapes as were borne by the Vine for I cannot say how many years, but twenty at the least, in the narrow one.

Do not let it be supposed that it is suggested the roots of the productive Vine in the narrow unprepared strip of ground were confined to it. Roots were there as thick as a mat, attracted and increased probably by a heavy layer of manure spread on every autumn, hidden by a sprinkling of soil, and fed by many a gallon of liquid manure, but others we may be certain wandered away. Equally certain, however, it is that they had firm soil to contend with, because they had to go into or under a gravel walk which has existed for probably a hundred years, or nowhere, for inside the house a flight of steps leads to a sunken path much below the level of the ground outside, and, moreover, at

that time there was a flue between the path and end of the house that I have many times seen red hot, and it is not very likely that the roots would pass through that, as the "bottom heat" would be rather too much for them. Wherever they went, therefore, they must have had to penetrate soil that had not been disturbed for generations. But it was not of a nature to run together like cement, and this brings me to some remarks of, I think, Mr. Arthur Young.

I have great respect for Mr. Young, with whose work I am quite familiar, and it justifies me in ranking him amongst the best of British gardeners. But even the best are caught napping at times. Though two fifteen or sixteen-stone men might jump on the Vine border at Cardiff Castle with impunity, it does not follow they might have a similarly safe dance on the Abberley soil in which Vines may be planted. Nor is it very likely either of the two heavy weights would do so, any more than they would jump about on the ground in preparation for an Onion bed like a pair of lumbering kangaroos. It is not improbable that the Abberley soil runs together very much like cement under a hot sun after a drenching rain. If this is so, the stamping process would be a work of supererogation, and if two sixteen-stoners were to be seen waltzing on such soil for firming it, it would savour of an example of zeal overrunning discretion. So many Vine borders are dug yearly and left so light that when stepped on deep impressions are made, and it is the opposite of this that is recommended for the subdivision of roots, and the consequent increase of absorbing points for extracting nutriment for the sustenance of Vines. That is what is meant by firm Vine borders.

As to the question of restricted root space and its results under skilful management, an example may be cited of Vines in pots. I am a believer in facts, and when I see, as I have seen, bunches of Muscat Grapes cut from a Vine in a pot, weighed, taken to a show, and place the fine examples cut from the gigantic Vines in the great vinery at Longleat in a second position, I am bound to recognise the efficacy of narrow borders. But in such borders the Vines must be fed, and they can be fed without souring the soil, which is no small advantage in the production of first-class Grapes.

How long Vines may be kept healthy and profitable in a border, say 6 or 8 feet in width, or even less, I am not able to say; but no doubt when the roof does not exceed in length of rafter half the width of the border they can be made to bear satisfactorily for a generation at least; and if the roots are pruned as the wood is pruned and new fibres formed in good soil, as new wood is produced after the manner described by "Bon Accord," I entirely fail to see that they will not continue bearing as long and as well as if they had four times the extent of space to ramble in. Those persons who think that all the roots of Vines that are produced in the summer live through the winter not improbably labour under a misapprehension. It is much more likely that with the fall of the leaves there is a correlative collapse of roots, and that the production of new leaves is accompanied by the emission of absolutely new roots and not the mere extension of old ones. That is a contingency in the economy of Vine growth that has not perhaps received all the attention it deserves, and hence the habit that has been formed of making needlessly large borders for Vines.—SPECTATOR.

NOTES ON HARDY PERENNIALS.

GENTIANA ACAULIS.

It may not be generally known that the autumn season is by far the most fitting for the successful planting of this fine old perennial, though it may be planted at other times, for it is very accommodating in this respect; but I incline to the belief that autumn planting is the best, for then the soil is uniformly moist, and the atmosphere heavily laden with moisture also, and this combined with the usual rainfall at this season of the year, having a tendency to make the ground solid about the plants, are all points bearing upon its well-being. I prefer solid planting for all Gentians which produce stoloniferous or underground stems such as this one, and, so far as my experience goes, the plants prefer it too, and this makes them very useful for edgings of a permanent character. We have no other of its class so easily grown and so handsome with its glistening blue flowers, of whose beauty I am still reminded by some flowers, even in November, which have struggled open in spite of the absence of sun. It is essentially a plant for those who love plants for their intrinsic worth rather than for their rarity and costliness; for bright and beautiful as many of our rarer Alpines are, the successful culture is limited indeed, and much still remains to be learnt respecting them.

MONTBRETIAS.

The several species and varieties of these, with which may be coupled *Crocus aurea*, should all be planted at once if not already done. The tone of the flowers, and the season during which they are produced, render them very acceptable autumn flowering plants; particularly effective are they when well established and at home. The great secret respecting them is the original planting. This must be well done. No plants more fully delight in a rich, moist, sandy, and well-drained light loamy soil than the members of these two groups, to which add fairly deep planting where they may be free from frost. All these points

require attention before a full measure of success can be attained. In planting, choose a warm sunny position sheltered from the north and east. Take out your soil to a depth of 1 foot, well fork up the bottom. Now give a good dressing of cow manure in the trench and cover with 3 or 4 inches of soil. A layer of sharp sand, old mortar rubbish, or the like, may be added with advantage. Then place in your bulbs and cover in with soil. According to the size of your bulbs will the first year's flowering depend, but if you allow them to remain for several years undisturbed you will annually be charmed with some of the most beautiful plants any garden can boast of. In general appearance they may be compared to a small *Gladiolus*, growing about 3 feet high, and having spikes of brilliant orange and gold flowers. *M. crocosmaeflora* is probably the best of this group, and has orange-scarlet spikes of flowers. The brilliancy of the flowers of these plants is such as to command attention in any garden where they have become established, and treated as I have here briefly described they are by no means difficult to grow, and at the same time increase very freely at the root, so that by liberal treatment a handsome bed of these charming flowers may soon be obtained. These remarks apply equally to the *Crocus*, which has brilliant orange flowers, and may be regarded as among the gems of autumn-flowering bulbous plants for the hardy plant garden.

TRITELEIAS.

I have at the present time a small bed of these in flower, planted late last spring, thus illustrating how a season's flowering of certain plants may be extended and even reversed. In effect the species and varieties of this little group are very pleasing when in flower, and continue sending forth flowers for a considerable time, and pretty as these appear, they are destined never to become popular on account of their decidedly objectionable odour.

COLCHICUM AUTUMNALE ALBUM.

This variety has far surpassed all the rest both in the freedom with which its flowers have been produced, and likewise their longevity. When the early frosts came and made such sad havoc of several acres of *Chrysanthemums* which were out of doors in this district, this Meadow Saffron was in full beauty, and in spite of frost night after night, this variety alone seemed to resist it. In the same bed with it stood the typical *C. autumnale*, also variegatum, speciosum, Byzantinum, and others, but all were more or less shattered and damaged by the rain and frost, while the subject of this note continued to produce its snowy white blossoms as though nothing had happened. Imagine such a one covered with flowers of snowy white thickly studded over a carpet, say, of some of the mossy *Saxifragas* thinly planted, or the dwarf Alpine *Phloxes* or *Pyrethrum Tchihatchewi*, *Aubrietias*, or in short anything which would just give the necessary carpet of leaves to keep their flowers clean in wet weather. That white varieties of certain plants are harder than the type has been proved by the *Lapageria* and *Camellia*, but I have never experienced so direct and positive a proof as this among the *Colchicums* before, and consider it worth remembering. The flowers are of such a useful size, and so pure withal, that it should be turned to good account by the florists. They expand with remarkable rapidity in a temperature of 60°, and quite took a visitor by surprise the other day, for whom I had plucked a few flowers which were in the bud, to find them fully expanded five minutes later when he had entered the greenhouse. Even when plucked they may be counted as among the most durable of flowers, and when I say that their flowering has continued unbroken for quite two months—not in ones or twos, for the flowers come in quantity from each bulb or corm—I think they may safely be regarded as among our best and most useful hardy plants, such as merit a more extended cultivation. The fact of their being quite hardy and remarkably cheap should be points favouring their general adoption. As a margin to large shrubberies or the like, or for the purposes of naturalisation, all the members of this group are very pleasing and effective—J. H. E.

NOTES ON GRAPES.

I READ with interest the notes on Grapes by your correspondent, Mr. H. Dunkin, on page 419, and while generally agreeing with him, I must take exception to some of his statements. One is, that Black Hamburg will colour quite as well in dull as in bright weather, and he advises shading at colouring time if the weather be very bright. I have seen Black Hamburg Grapes this year at several places, and they have not been well coloured. In some cases, where grown alongside of Alicante, the latter has been the better coloured of the two. In our own case in the late vinery Black Hamburg, which promised well for a time, did not finish in colour as well as Alicante or Lady Downe's. Again, if this Grape colours quite as well in dull as in bright weather, why do we see so many

"red" Hamburgs in the market? I do not think we could have a brighter summer than 1887, and yet there was no need (in our case, at least), to have resort to shading.

With regard to Madresfield Court cracking, and front ventilation, I think your correspondent is in error when he states that in a succession of wet days the moment the front ventilators are opened the damp air finds its way into the house and cracking takes place in a few hours; but when the front or bottom ventilators are at once closed and more heat kept in the pipes, cracking is arrested, and it is want of bottom ventilation that has to answer for want of colour in Madresfield Court. I maintain that bottom ventilation will not cause Madresfield Court to crack if it is given judiciously. When visiting the gardens at Fernclough in early summer, Mr. Herd, the gardener, told me he always left the front ventilators open a little night and day, and is never troubled with cracking, and he grows this noble Grape as well as anyone need wish to see it. He maintains that if there is sufficient heat in the pipes the air coming in at the bottom is warmed before it passes through the house and up to the Grapes. Be that as it may, I did not observe a cracked berry then, nor when looking at them a few weeks ago. They were all well-finished bunches about 4 and 5 lbs. in weight. It is only right to say they are not so dark in colour as in brighter summers.

We took the hint, and have left front ventilation on our vineries ever since, and have not observed a cracked berry. I maintain this is sufficient proof that bottom ventilation will not cause cracking in Grapes. This is a very wet district in this part of Lancashire, and should be a good test of the theory put forth by your correspondent. I believe we would have less of cracking and scalding if a little ventilation were left on in front night and day, and plenty at the top during the day at stoning time, with sufficient heat in the hot-water pipes to maintain the desired temperature.—G. HILTON.

THE NATIONAL AURICULA AND THE NATIONAL CARNATION AND PICOTEE SOCIETIES.

A FULLY attended meeting of the members of the Committee of the London Societies took place, by the kind permission of the Horticultural Club, in the rooms at the "Hotel Windsor," on Tuesday, the 11th inst., the Rev. H. H. D'Ombra in the chair. The minutes of the last meeting having been read, it was resolved that the offer of the Council of the Royal Horticultural Society to give the sum of £10 to each of the Societies be accepted, and it was arranged that the Exhibition of the National Auricula Society should take place in the Drill Hall, Westminster, on Tuesday, April 23rd, in connection with the meeting of the Royal Horticultural Society on that date; and that of the National Carnation and Picotee Society on July 23rd, also in conjunction with a meeting of the Society. The Council having expressed a desire that something in the form of a Conference should take place at each of the Shows, having reference to the particular flowers exhibited, by way of imparting additional interest to the Society's meetings, a sub-Committee, consisting of the Rev. H. H. D'Ombra, Messrs. Selfe Leonard, R. Dean, and J. Douglas, was appointed to make the necessary arrangements and report at a future meeting of the Committee. The schedule of prizes offered at the Exhibition of the National Auricula Society was passed in the form in which it appeared at the last Show, and a few alterations were made in that of the Carnation and Picotee Society. It was decided that yellow ground flowers be no longer shown with selfs and fancies, as there is a class for them. That for twelve blooms was reinforced by one for six blooms, it being understood that yellow selfs can also be shown in these classes. Mr. Douglas having drawn attention to the fact that there is in the hands of the Treasurer a balance from the two Societies amounting to £40, suggested that a portion of this should be invested as a reserve fund, and eventually it was agreed that £25 be set apart for the purpose of forming a reserve fund, it being left to the Rev. H. H. D'Ombra, Messrs. Selfe Leonard, and J. Douglas to make the best investment they could. The proceedings closed with thanks to the Horticultural Club, and also to the Chairman for presiding.

MEALY BUG IN VINERIES.

HAVING read with interest the excellent articles which have appeared in the Journal on "The Vinery in Winter," I thought I would venture to state how I got clear of that terrible pest the mealy bug.

A little over two years ago, when I obtained my present situation, the vineries, of which there are two, were terribly infested with the pest. The Grapes in one of the houses were so bad that I had most of them burnt, only leaving a few that were clean to ripen. Some may say, Why not burn Vines too, and plant again? which, for my part, I would have gladly done; but there are always two sides of a question. The place was taken on a lease for a short period, so it could hardly be expected that we should plant and grow young Vines for a new tenant, so I had to do my best to eradicate the pest.

As we had other duties pressing, it was almost Christmas before we had a start to clean. We had some very hard frosts during the month of December, and it was welcomed inside the vineries, throwing the

doors and ventilators wide open. Commencing cleaning operations, I had everything moveable taken outside the house, thoroughly washed and soaked with petroleum, and laid aside until wanted. Then taking down the rods, pruning them, and scraping off all the outer bark with a blunt knife, had them tied along the front and to one end of the house, and commenced at the other end to scrape all the loose paint off the ironwork, cleaning two sashes at first, washing them with softsoap and water as hot as we could bear, scrubbing well with a hard brush every crack and crevice, taking the Vine rods as we came on them, and washing them the same as the house. After we had gone over everything under the two sashes, not forgetting the end and back wall, we had the garden engine filled with water, and to every 3 gallons of water we added $\frac{1}{2}$ lb. of petroleum, keeping it well stirred, applying it to every part with great force, including the Vine rods underneath those two sashes, and so on in the same way until we had been over the whole house. After that I had a few inches of soil taken off the inside border and fresh substituted, and then gave the house two coats of paint, and the back wall was washed with hot lime, and that finished one house, and the other was done exactly in the same form.

When starting time came I was much afraid I should never see life in the Vines again, but they came away very well. I must admit they did not carry a full crop of Grapes the following year, but they were very creditable, and not a bug to be seen, although I scrutinised them closely. I may say that petroleum, softsoap, and soot are the three best insecticides I ever tried.—N. B.

REVIEW OF BOOK.

The Rose Garden. By WILLIAM PAUL, F.L.S. Ninth Edition. London: Kent & Co., Paternoster Row.

MR. WILLIAM PAUL has contributed ably and liberally to the literature of Horticulture over a long period, and his works on various subjects afford evidence of thought and care in their preparation, and of the possession of scientific and practical knowledge by their author. Naturally his chief writings are on the Rose—"Roses in Pots," "Roses and their Culture" and "The Rose Garden," have proved their wide acceptability, six editions of each of the two former having been published, whilst the latter has reached a ninth edition. "The Rose Annual," also issued over a series of years, was remarkable for its beautiful coloured plates, as well as for the excellence of the letterpress matter. At present, however, we have to direct attention to the latest and best of those works—the ninth edition of "The Rose Garden." This is in two forms—one royal 4to, with twenty coloured plates and sixteen full page engravings; the other imperial 8vo, without plates and large engravings; but both have eighty woodblocks in illustration of the text. To the former we shall more particularly refer, as it is a distinct departure from the previous series, and a bold and beautiful advance on them all.

It is in every way admirable, paper and printing being of the best, illustrations clear, and the coloured plates of Roses unsurpassed for fidelity and finish, and their beauty is well displayed on the ample space the pages afford. These, it may be said, are of the same size as the pages of this Journal, and as there are 360 of them, an idea may be formed of the magnitude of the work.

The handsome volume before us, like its smaller predecessor, is arranged in two divisions. I. Embracing the history and poetry of the Rose, the formation of the rosarium, and a detailed account of the various practices adopted in the successful cultivation of Roses in pots and in the open ground. II. Arrangement in natural groups of the most esteemed varieties of Roses recognised and cultivated in the various Rose gardens, English and foreign, with full descriptive remarks on their origin and culture. The comprehensiveness of the work is thus apparent. The matter in previous editions has been carefully revised and in great part re-written. The history of the Rose has been much extended and is very full and interesting, and so well is the work brought down to date that the chapter on new Roses includes the varieties introduced or announced during the present autumn; and the lists of varieties for various purposes and positions, which is one of the most useful features of the work, have been thoroughly revised, and may be regarded as in every way trustworthy.

Some portions of the matter in former editions we imagine could not be improved; for instance, the remarks on exhibiting, and the way in which reverses should be met. These remarks have a wider application than to exhibitors of Roses alone, and are so good and pertinent that they are worth reading again and again, hence worth citing. Here, then, is a fragment of the chapter, the moment being chosen when exhibitors enter a show and first see the verdicts of the Judges:—"A feeling of disappointment may arise. Shall we take umbrage when our positions are not so high as we expected? Certainly not. This would be foolish and ungenerous. Let us ask ourselves this question, Which is the more likely, that the censors—men selected on account of their professional knowledge and probity—which, we say, is the more likely, that they should have shown an indifference to or prejudice against our exhibits, or that the owners thereof have been indulging in an overweening fondness? The answer is apparent. And let us ask ourselves again, if there is any disgrace in being beaten? Certainly not. Every place here is honourable. If A produces good plants it is no discredit to him that B produces better. Nor would it always be correct reasoning to say that the latter is the more skilful cultivator. The air, the soil, or the means at disposal of B may enable him to accomplish with ease that which is impracticable with A. If our plants (or blooms) are good, never mind those of our contemporary being better. Are not both engaged in the

same work, both interested in the advancement of a favourite flower? Let us persevere, and we may probably reach the summit of our ambition at some future time." At Rose shows verdicts are usually accepted gracefully, but there have been exceptions; and at some other exhibitions unseemly action on the part of disappointed men has not conduced to the pleasure of visitors, and no harm therefore would be done if the words quoted were printed in bold type and suspended in the offices and packing sheds of individuals who wish to be exhibitors and judges too—awarding themselves the first prizes. But we must pass on.

A new chapter in the work under notice on the "Poetry of the Rose" could not have been compiled without great research, nor could the selections have been made in the absence of literary taste. Examples of Rose poetry are given from Greek, Roman, Persian, French, Spanish, Portuguese, Italian, German, Russian, and English writers, the latter including Chaucer, Spenser, Shakespeare, Herbert, Walton, Fanshawe, Cowley, Waller, Cowper, Burns, Scott, Wordsworth, Browning, Coleridge, Moore, Lytton, and others, the whole occupying twenty pages of the work. In the first example given we find the origin of the familiar appellation, the "Queen of Flowers," penned by Sappho 2000 years ago:—

"Would Jove appoint some flower to reign
In matchless beauty on the plain,
The Rose (mankind will all agree),
The Rose the queen of flowers should be."

There is much delightful reading in the various ballads, sonnets, and songs of and to the Rose, and many good sentiments charmingly expressed; one, among others, by Clare, having historical significance, taking us back to days of turmoil, and bringing us to the present, when liberty and loyalty are happily united:—

"The Rose is red, the Rose is white,
The Rose it blooms in summer light;
But, ah! it clouds the heart's delight
To muse upon its history.
It tells full many a woeful tale,
Of hearts made cold, of cheeks made pale,
Of love's sad sigh—the widow's wail,
In days of strife and chivalry.—
Sweet Freedom, may the age prevail,
That strife no more may be."

"The Rose is red, the Rose is white,
The Rose is pleasant to the sight;
Now both its hues in one unite.
To crown the brows of loyalty!
Strife took the white Rose for its crest,
But Concord placed it in her vest,
Where deep it blushed upon her breast,
To wed the tree of Liberty;
And while it blooms as Freedom's guest,
There let it ever be."

Another addition is of a very practical kind, a calendar of operations in the Rose garden for the several months, commencing in October, as the beginning of the Rose grower's year. The instructions are concise and to the point, and it would be difficult to take out a sentence without impairing the usefulness of the timely hints given. Calendars too often betray a desire to spin out sentences for covering space and manufacturing pages, but this is not one of them. The article on the "Botany of the Rose," originally prepared by the late Mr. Thomas Moore, has been revised, and much of it re-written by Mr. J. G. Baker of Kew, who does not undertake to do anything that he does not do well; and the full and excellent chapter on the entomology of the Rose has been revised by its author, Mr. Arthur W. Paul, who has evidently spared no pains in rendering it as instructive as it is ably written.

In the production of this edition of "The Rose Garden" the materials collected during a period of forty years are arranged in a systematic manner, nearly every item being indexed, and the reader can easily seek and find information on almost every point on which he requires it in connection with the Rose. The work may be fairly described as a complete one—a work of which, taking it all in all, substance, execution, and comprehensiveness, we know no equal on the subject. There is not a public library in the kingdom it would fail to enrich; and it is not easy to conceive of any lover of the Rose with a guinea to spare who could be disappointed by its investment in the beautiful volume before us. And those who cannot indulge in the *édition de luxe* will find a wealth of information in the less highly embellished yet well-finished companion issue above referred to, and both are commended to the different classes of readers to which they appeal.

HARDY FRUIT GARDEN.

TRANSPLANTING TREES.—The wood on young trees especially has ripened badly, many still holding much of their foliage. In all such cases early transplanting is almost certain to result in a portion of the young wood shrivelling never to plump again properly. Those who were in a great hurry for their young trees will, in all probability, have cause to regret their haste. It is wise to order the trees early, but the nurserymen ought to be allowed to use their own judgment as to the advisability of lifting and despatching as soon as the order is received.

Those who may wish to transplant any trees already established on the place, and it is a good plan to regulate those against walls and in the open occasionally, ought always to wait till the greater portion of the leaves are fallen. At the present time all but Peach and Nectarine trees have shed their leaves, and the work, therefore, of transplanting Apricot, Cherry, Plum, and Pear trees ought to be pushed forward while the mild weather continues. The aim in all cases should be to secure a moderate sized ball of soil about the roots, and to preserve as many of the latter as possible. A trench must be opened at least 4 feet clear of the stem of a moderately large tree, and still farther off if extra large specimens are to be moved. Then, if the roots are well undermined with the aid of forks, and gradually traced to near the stems, only a few of them need be broken. The ball of soil and roots being slipped on to a stout board or legless hand-barrow may easily be lifted out of the hole, carried to its new site, and replanted. Always plant rather high to allow for the natural settlement of the soil, cleanly cut away all bruised roots, as well as the jagged ends of the sound ones, and distribute these evenly through the soil, keeping all as near the surface as possible consistent with safety. Transplanting fruit trees frequently greatly improves their productiveness, and if given plenty of fresh loamy soil or chopped turves the quality also will be improved.

LIFTING FRUIT TREES.—Lifting as distinguished from root-pruning usually consists of undermining and completely raising the tree and returning it to its original site again. It is more often necessary in the case of much-restricted and miniature trees, and being practised every two or three years checks luxuriant growth without spoiling the prospect of a full crop the following season. The first time the trees are lifted many of the roots will have spread to a considerable distance, and these have to be cut through at about 3 feet from the stem. This, in addition to checking injuriously deep root action, also induces the formation of abundance of root fibres, so that in after years quite a compact mass of fibres will be found when the lifting time comes round again. Any trees clear of walls, notably pyramid and bush Apple and Pear trees, ought when lifted to be half turned round, and in this manner each side in its turn gets the full benefit of the full sunshine, an important proceeding, the benefit of which ought to be apparent enough. A small portion of fresh loamy compost ought to be disposed about the roots each time the trees are lifted, this being the means of sustaining the fertility of the trees as well as insuring the perfecting of much finer fruit. Lifting is by no means a very formidable job, and in the case of eordon trained trees is absolutely necessary, or otherwise there is every likelihood of much growth and little or no fruit being produced by them. Much stunted trees ought to be lifted and replanted in rich compost.

ROOT-PRUNING.—This is a more gradual and less severe process than lifting, and acts most beneficially where given a fair trial. When a large tree is wholly lifted it experiences a check from which it does not recover for two or three years, a much stunted growth being the almost sure consequence. It should be remembered that root-pruning is advisable in most cases where the trees invariably form an excessive quantity of wood, and produce little or no fruit. The root-pruning being judiciously carried out, the exactly opposite state of affairs—viz., abundance of fruit and a moderate quantity of growth will, frosts and birds permitting, be induced. Rank growth and unfruitfulness is usually consequent upon a deep and widespread root-action, and this must be checked before abundance of root fibres will form near the surface. An improved root-action is soon followed by more fruitful growth, sturdier well-ripened wood being best calculated to bear abundance of fruit. There are two methods of accomplishing this desirable end, one being completed at once, the other in two or more seasons. Comparatively young trees, or any that have only just furnished much of the space allotted to them, will not, as a rule, have formed any very stout wide-spreading roots, and will also be furnished with a moderate quantity of root fibres or smaller roots. Such may have a trench opened round them at a good distance from the trees, and the roots carefully bared to within 2 feet of the stems. All being duly shortened and relaid in fresh turfy loam or ordinary garden soil, and in every instance brought as near to the surface as possible, nothing further will be needed beyond mulching the ground early in the summer. Much older trees treated similarly might end badly, and the safest course is to partially root-prune, and complete the operation next autumn or early in the winter. In this case the trees should be root-pruned on one side only at a time. Sometimes the trees derive nearly all their support from a few very strong wide-spreading or deep-running roots, these may be needing cutting through with a saw. In such instances the root-pruning must extend over three seasons, a year's interval being necessary for the proper recovery of the severely shortened roots. Or to be plain, the second half of the roots must not be cut before those first operated on have formed abundance of fresh root fibres. The undermining must be thorough, or the strongest deeply running roots will probably be missed, and it is owing to these that much sappy wood and inferior fruit are produced. This method of root-pruning and renovating the trees will not be complete unless abundance of fresh loamy soil, with the addition of fine bones be used. Soil long occupied by the roots of trees will not encourage the formation of abundance of root fibres, but a fairly rich compost will, and is also necessary for the well being of the trees.

FRUIT FORCING.

VINES.—*Making Vine Borders.*—Where young Vines have to be planted in spring advantage should be taken of suitable weather for securing compost and getting the border prepared for their reception.

Drainage being the first essential, this part of the work must be well done. Place 3-inch tiles with proper fall and outlet to carry off the water passing the drainage, and if the bottom of the border be wet, or subsoil unfavourable, it ought to be concreted, than which nothing answers better than two parts gravel and one part cement formed into a mortar-like mass. The gravel should be fine as for garden paths, and be 4 to 6 inches thick. The drainage must be clean and not less than 9 inches thick, better a foot, the coarsest at bottom and finest at the top, which may be covered with the coarser parts of old mortar rubbish, using that remaining in a half-inch sieve after sifting the finer particles out. The finer portion will do for mixing with the compost, but be careful to remove from the mortar rubbish all pieces of wood or old laths. The drainage may be covered with a thin layer of turves grass side downwards. Thirty inches depth of border is ample, which may consist of good turfy loam—i.e., the top 3 or 4 inches of a pasture taken off with its turf and chopped roughly. A rather strong calcareous loam is best, as the Grapes are found to attain larger size and have a better colour and finish than when light soil is employed. Light soil, however, may be improved in holding texture by an addition of clayey marl, a fourth to a sixth according to the nature of the loam, whilst a strong clayey loam may have similar proportions of old mortar rubbish or road scrapings incorporated with it. Surface loam rarely contains sufficient calcareous matter, and old mortar rubbish is too sleepy for these go-ahead days, so it need only be used to keep the soil open, to hold moisture, and a source of lime as the Vines require it, but chalk would perhaps be preferable. What is found to answer best is quicklime, as much as a tenth being incorporated with the fresh loam, thrown in a heap and thoroughly mixed before putting in the border, where it should remain about six weeks before planting the Vines. Charcoal may be used to the extent of a twentieth, and steamed crushed bones to the extent of a fortieth. The fresh lime causes the better and earlier assimilation of the fibry matter as food, and the Vines are not so liable to make a gross growth with a corresponding large pith; indeed the wood is more ligneous, and what is lost in grossness is counterbalanced in hardness of wood and plumpness of buds. It is advisable to keep the border well above the surrounding ground level, especially in low damp situations, and give the surface a good slope to the front, so that when covered rain and snow is thrown off. A 4-foot width is sufficient to start with, and should be inside, the roots being confined to it by closing the apertures in the front wall, as it is advisable to have the inside border well filled with roots before admitting them to the outside.

Young Pot Vines.—Those intended to be grown into fruiting canes may be cut down to a couple of eyes or close to the pots, dressed with styptic, and placed in a succession house, which will be started early in January. Single eyes may also be inserted in small pots or in pieces of turf, and kept cool for two or three weeks before they are placed in bottom heat.

Midseason Houses.—Proceed with pruning the Vines, as they break and show better when they have a good season of rest. They should be dressed, and the house thoroughly cleansed ready for a fresh start when the proper time arrives. The loose inert surface soil must be removed down to the roots, and a layer given, 2 or 3 inches thick, of fresh loam, to which has been added a sprinkling of bonemeal and charred refuse. Keep the houses cool and dry until the time arrives for closing. If they must be used for plants, keep them 40° to 45° by artificial means, and as dry as practicable.

Late Grapes.—Examine these at least twice a week for decayed berries, and keep the house as cool and dry as may be consistent with the safety and preservation of the fruit. When thoroughly ripe and the Vines are leafless, a mean temperature of 50° is suitable until the time arrives for bottling. Anything much below this is liable to cause mould and decay; and fire heat, especially at night, will undoubtedly cause the berries to shrivel immediately after the fall of the foliage. No further time should be lost in preparing the Grape-room ready for the stock of keeping Grapes, which must be cleared off the Vines not later than the first week in January, and a week's steady firing is necessary to expel damp. The certainty with which Grapes keep bottled for four or five months in better condition and at less expense has given confidence in a system which affords relief to the Vines, insuring that perfect rest so essential to their after well-doing. Gros Colman requires the longest time of any on the Vines, as it takes colour after the foliage is ripe, and owing to the soft fleshy nature of the footstalks, which are likely to decay, it is best kept in the driest and warmest part of the Grape-room, by which means it parts with its earthy flavour and improves in quality. To do well, it requires to be started early—by the middle of February—not later, as it needs a long season of growth, and the fruit ought to be finished by the end of September.

CHERRY HOUSE.—The trees having been duly attended to in pruning, dressing, &c., the house can now be closed. Let the treatment be such as will not excite growth prematurely, therefore only allow a slow progression. A temperature of 40° to 45° at night and 50° in the day will need to be maintained by artificial means. When the external conditions, however, are favourable a few degrees higher may safely be permitted, but anything calculated to bring the trees on too quickly must be carefully guarded against, as undue excitement at the commencement is likely to prove injurious to the crop. Ventilate at 50° just a little at the apex to insure a change of atmosphere, ventilating freely at 55°, allowing an advance of 65° or 70° with sun, and closing at 55°. Moderate moisture in the atmosphere will be attained by syringing occasionally, but in all cases allow the trees to become dry before night. It is highly important that the borders be thoroughly moist, as

when the trees are excited into growth fresh roots will speedily be formed, and to encourage them moisture is absolutely essential.

STRAWBERRIES IN POTS.—The weather has been mild, but it is not desirable to push the plants forward, as they are not very well developed in the crown through the prolonged cold summer, therefore proceed cautiously, and there is not greater need for it than in Strawberry forcing, in frosty dull weather, allowing the temperature inside to fall corresponding to that of the outside, seeking only progress when there is sunshine, or at least gleams of it, when heat may be turned on early in the day so as to rise and maintain a temperature of 50° to 55° through the day, and the walls and paths may be damped, but only when there is a prospect of sun, so that the moisture by its action and that of a little air will have dried up before night, and the temperature should fall to its minimum of 40° to 45°. Continue this under adverse circumstances until the new year, after which it is surprising how the plants progress with comparatively little aid. The system of starting Strawberries on beds of leaves and dung in a fermenting state is a bad practice, as it starts the roots into activity for no purpose, Nature itself being the best prompter in this respect, and unless the plants have already a sufficient number of roots they are unfit for forcing. It is a good plan to start an equal quantity of two sorts, so that one variety will come in after the other in successional order. Be careful to allow the plants sufficient water, examining the soil daily.

PLANT HOUSES.

Allamandas.—Plants that have rested for six weeks or two months may be started into growth. Potting can be done while the plants are in a dormant state or after they have commenced growing. The first is perhaps the most suitable time, for it is almost impossible to repot the plants after they have started growing without injury to some of the young tender shoots. If the plants are grown in pots turn them out and reduce the old ball by half. They should then be soaked in tepid water and allowed to drain thoroughly before repotting. Well drain the pots and press the soil in firmly. If the pots can be plunged no water will be needed before the plants have started into growth, but light syringings with tepid water twice daily will be beneficial. Use for a compost good fibry loam, a little sand, and one-seventh of decayed manure. Allamandas planted out or grown in restricted borders should have a good portion of the surface soil removed and rich material supplied. In this case one-third or even one-half of decayed manure may be used.

Clerodendrons.—The earliest plants may be started under the same conditions as advised for Allamandas. Soak the ball in tepid water, which will be all the water needed at the roots until growth has commenced, when repotting should be done. In this matter some care is needed, for these plants resent their roots being unduly disturbed. Only reduce the ball carefully by one-third. Use the compost advised for Stephanotis with the addition of one-third of leaf mould. These plants will do well for years in the same pot provided a top-dressing of manure is given, with liberal supplies of liquid manure during the growing season.

Bougainvilleas.—If all the weak shoots have not been removed cut them out at once, and only retain the strongest and best ripened of last year's wood for laying in. Cut back shoots that are not wanted for this purpose to one or two eyes at the most. Start the plants into growth the same as Clerodendrons, repotting and top-dressing them in the same way, but employ the compost advised for Allamandas.

Epiphyllums.—If these are wanted in flower introduce them into heat; a temperature of 55° will do very well. These plants are handsome when in flower if they are elevated above a groundwork of Ferns. In no position do they look better than in association with *Adiantum cuneatum*. Be careful not to give too much water, and at the same time do not keep them so dry that they shrivel. This is fatal to the stock upon which they are worked.

Callas.—If these are not coming forward rapidly enough place them in gentle heat, and they will quickly push up their spathes. All intended for late spring flowering should be kept as cool as possible, or they will draw up tall and weakly. Be careful to have the plants free of aphides, for if they exist on the foliage of the plant they are certain to establish themselves on the spathe directly it appears. Aphides are easily removed from these plants by fumigating with tobacco, or by sponging the leaves with diluted tobacco juice.

gathering all unused pea meal they could. The great storms of wind and rain have destroyed the bloom of all flowers more than any frost that has been experienced this season. In our locality hives with wide entrances and one-piece floor and alighting board, where facing the storm, are deluged with water.

SUPERING.

"When shall I put on my supers? and what is the reason my bees will not take to their supers, but swarm or lie out instead?" These are queries that are asked over and over again. I will endeavour to make supering intelligible.

In this country the honey season is so short and uncertain, that we often cannot say long beforehand what must be done. The great object of the bee-keeper is to make sure his hives are in "full strength." I must emphasise these two last words, because it is on them alone that success depends, and full strength means that the hive must be full size. Hives of ten standard frames only have been the cause of much disappointment and needless expense to the cottager for whose benefit they were said to be introduced; but why a smaller sized hive for cottagers? Are not their bees as good workers and gatherers of honey as those of the rich man, who has had a hive at least a half larger? and yet we are never out of hearing of the cry what certain advisers have done for the cottagers of Great Britain.

Bees will never work in supers satisfactorily that have too small a brood nest, such as in the ten-framed hive. Often before the time comes for putting on supers the bees of these hives have prepared for swarming, and will either swarm or crowd out rather than enter the supers. Owing to the limited capacity of the hive many eggs are destroyed, and the swarm from it being in proportion to the size of the hive, rarely makes headway enough to be able to fill supers in our fickle and transitory honey seasons. It generally happens that the honey season follows immediately after a term of changeable weather with a low temperature. Before, and during this time, the bee-keeper should use every precaution that there be no waste of eggs or larvæ, nor anything likely to give the hive a check; breeding must be kept up without intermission. The well-managed and full-sized hive will, during this time, increase greatly in bees, so much so, that immediately the weather changes the hive becomes intolerably hot. This, supering will at once relieve, the bees taking to the supers in the nick of time. They work with a will until some other change comes, such as every cell of the hive being occupied, then the bees start royal cells, and swarming will take place, no matter what room, or how it is provided. The swarm from such a hive will generally take to supers if the weather is fine after a few days, provided it has been put into two body boxes instead of three, or much better where two swarms have been joined.

A very old custom to compel bees to take to supers, consisted in adding a "winter raise"—i.e., a shallow box, which was used underneath the hive during winter. This box was also used when the bees were ahead of the season by putting it right beneath the hive, where the bees would descend and build snow-white comb. After a few days and before brood was in it, it was taken out and supers put on, when the bees immediately took to them, and the new built combs were used as guides for supers. How these combs were fixed I recorded in the pages of this Journal nearly thirty ago. The top bar was split and the side walls of the comb were pared away until the midrib only was left for about a quarter of an inch down, and then placed between the split bar. These were, perhaps, the first split bars used. Another plan was to smear the under side of the bar with wax, which was slightly heated and the comb straightened by being run along a heated smoothing iron, then applied to the waxed bar, when it adhered sufficiently till the bees made all firm. These were called "toaks" in Stewarton, where they were probably first used. Comb foundation has supplemented these, but has not improved the quality of the super when nothing but the delicate pure natural comb was used.

THE BEE-KEEPER.

NOTES.

FOR some days previous to, and until the 6th inst., the weather has been changeable, with excessive rains, but always accompanied with a high temperature, a sure precursor of wind. For nearly a week in succession the mean temperature has been 50° Fahr., the highest being on the 4th, when the night temperature was 50° and the day 56°, being a mean of 53°. The bees during these days were active, and searching the *Arabis* for pollen, as well as

The foregoing brief hints may be regarded as the essence of successful supering, which consists in having hives in readiness in and at the right time, and not attempting supering until there are bees to fill the supers and attend to the brood. In "Gleanings" for November 15th Mr. G. M. Doolittle has a sensible article on supering, in which he objects to the tiering up of supers—that is, if I understand him aright. He ably points out its defects, and shows the way bees work naturally, abhorring a vacuum—just as I have repeatedly pointed out to the readers of this Journal. His mode of supering is in accordance with the natural working of the bees, giving them at first space right in the centre and over the cluster and extending on both sides gradually as the bees can get on with comb-building. But, however plausible his argument is in this last respect, and however "natural" the process is, it would never be successful in this country. To attempt such here the honey season would come and go before anything like a harvest was secured. In countries where fine weather is of long duration, and where hives with fewer bees than obtain in this country can gather more honey by reason of length of time, the plan may do very well. But in this country a hive is not ready, nor in a fit state for supering, until the bees are numerous enough to take possession of and fill rapidly supers equal at least to a third of the size of the hive. Moreover, it is a mistake to attempt supering with the centre spaces over the brood nest open, as I have shown frequently. Mr. Doolittle argues the thing reasonably and fairly and in accordance with the nature of bees, but his country is different from ours.—
A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

James Carter & Co., 237 and 238, High Holborn, London.—*General Seed Catalogue, highly illustrated.*

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (Subscriber).—It is doubtful if any work will suit you better than the "Cottage Gardeners' Dictionary," price 8s. post free from this office. It is very comprehensive, and as you will perceive much less costly than the work you name. (*Shelley*).—We do not know of a good book on the subject you name. (*H. M.*).—The sixth edition of "Mushrooms for the Million" is in the press.

Bellissime d'Hiver Pear (G. L. C.)—This is a very good culinary Pear, some persons, however objecting to it because it is not quite firm enough for them, preferring Catillae, even if it is sometimes gritty at the core. The first-named makes a very good pyramid, and on that account would be suitable for your purpose.

Pine Apple (T. J.)—The crown is formed of the leaves, and they are of the same use to them as are the leaves of all the plants in the same tribe. If the crown is proliferous, reduce it to one as soon as apparent. Bad cultivation causes an excess of crown, such as too little heat and deficient light. Small crowns are always preferred.

Analysing Soil (J. Moorby).—We believe Dr. Voeleker undertakes scientific work of this kind, and you may write to him on the subject, his address being Salishury Square, Fleet Street, London, E.C. He will advise you on the quantity to send and the depth of procuring it for your purpose, if you make this known to him.

Chrysanthemum Sport (T. S.)—Unquestionably the large flower sent is distinct from the type, this being a well coloured bloom of Empress Eugenie. The "sport" is reflexed, and better than many we have seen in the stands of that section this season. Fix it if you can with the object of ascertaining its true character. There have been many abnormal blooms this year, which we suspect are peculiar to the season, and may not be seen again.

Fruit Trees on Clay Subsoil (Burton).—Make stations, or mounds, upon the surface of your garden, as frequently recommended. Plant the trees upon them, cutting away any descending roots, and training out the lateral roots regularly all round, and near the surface. Keep that surface mulched and undug. By this means the roots will be induced to remain near the surface. If you destroy the surface-roots by digging, others will be formed deeper in the soil, and these getting into the clay will induce canker.

Pruning Deutzias (D. O.)—They should be pruned like Gooseberries and Black Currants—that is, getting rid of as much old wood as you can, and leaving the young to flower and make flowering wood; in two words, remove the old and spare the young wood every time you prune them, but then you are not on that account to cut away more old wood than will keep the bushes moderately thin. A young shoot here and there that is longer than the rest, or out of shape, is to be cut in keeping the bush uniform in shape.

Plan of Garden (P. E.)—There is not one of the present beds in the right place, for this reason—there is not a place for any of them. We would not do away with the walk across the end from the entrance by any means, nor the border on the right going to the kitchen garden, as that border no doubt was intended for evergreens; but if the flower garden were to be levelled and laid out in the geometric way, that border ought to form a part, and then the grass to reach the side of the walk to the kitchen garden.

Wintering American Aloe (A. S.)—The plant will do very well in the hall if the stove does not raise the temperature above 50°. If it raised the heat much above that it ought to stand near a window, and if not suitable to give it light you will keep it better in the stable at the farthest corner from the horse, allowing it to be dry, covering it with a cloth and hay in bad cold weather, and now and then, when the weather is fine and mild, setting it out of doors for a few hours. It will keep very well in any dry cool place provided frost is excluded.

Rockery Water Basin (G. James).—The best and cheapest way of having a water-tight basin in a rockery is to build it with bricks in cement, and to plaster the inside of it with best Roman cement. Then to build the rockwork round it, to form the lowest side into a valley, and to get the waste water to run there, or to stands in pools or lakes; and to plant marsh plants and water reeds to shelter and shade smaller kinds along the banks. Nothing is more easy than to remove the most of our Ferns in mild weather, from September to the middle or end of March. Take good balls with them and observe how they grow. But naturally some are on dry banks, some in deep sandy loam, some in very dry exposed places, and some the contrary. No guide is better than Nature in Fern culture.

Coriander (Youngster).—The leaves of this are used both in salad and in soups for their high and peculiar aromatic flavour. The seeds are used medicinally, and are considered soothing and stomachic. They are also sold by confectioners, encrusted with sugar. If required early the seed is to be sown thinly on a hotbed in February or March; and when 3 inches high the plants are ready for use. As they will soon run to seed another sowing must be made in April for a succession. This may be done in an open, warm situation, in drills 6 inches apart, an inch deep, then covered over with light earth with a rake. When the leaves are 3 or 4 inches high, they may be gathered for use by cutting them off close to the ground. To have a supply all the summer a little should be sown every month, as it soon runs to seed. For winter use it may be sown in August and September on a warm border; and when cold weather sets in the plants must be hooped over and protected.

Early Tomatoes (S. S.)—Certainly you may commence earlier than March—sowing the seed at once or in January, if you can keep the plants sturdy, for this purpose cultural skill requiring to be added to suitable structures. We do, as you suggest, endeavour to exercise the virtue of patience in dealing with the questions of correspondents when we can aid them in their difficulties. This is, in one respect, particularly necessary, as they so often overlook or forget the precise information that is required, and where it is given in fuller detail than is practicable in the form of a reply. A position close to the glass, and a temperature of about 65°, falling to 60°, is necessary for raising Tomato plants very early in the season. Roses are best not forced the first season after planting, and especially if soil was shaken from their roots in the process or if they were dug from the open ground. Bonemeal is excellent for incorporating with the soil for Tomatoes, a little potash further improving it.

Pruning Ipomæa Leari (S. Gordon).—The Ipomæa Leari is one of the best conservatory climbers; but it will be apt to suffer if the average temperature at night in winter be long below 45°, and especially if the main stem be near the glass of the roof, where it would be most quickly cooled by radiation on a frosty night. If the plant consist of one main strong stem, with flowering shoots coming from that main stem all the way, then each of these shoots may be pruned back now to

within three or four joints or buds from the main stem. In spring, after winter is past, you may prune back to one or two buds, as it is from the shoots produced in summer from these buds that the flowering takes place. If the plant be not furnished with a stout main stem, it would be advisable to merely partly prune now and again in spring. Prune in such a manner as to leave a sufficient amount of buds to produce shoots regularly all over the plant; say, to procure a stout shoot, every 15 or 18 inches; and these will look best if allowed to grow downwards as dangles from the main stem and rafters. If your house be kept cool in winter it would be advisable to suspend the main stem 2 or 3 feet from the glass.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*Newark*).—The Apple you have sent under the name of Cox's Orange Pippin resembles Fearn's Pippin, but the fruit has apparently been gathered too soon, hence we cannot be certain of its identity. The other we do not recognise, and it is probably local.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*J. Leech*).—A narrow petalled form of *Oncidium inervum*. (*W. E. C.*). —1, *Eranthemum pulchellum*; 2, *Correa speciosa*; 3, *Aster horizontalis*; 4, *Tetradlea verticillata*; 5, *Pentas carnea*; 6, *Crassula lactea*.

COVENT GARDEN MARKET.—DECEMBER 12TH.

NO alteration. All classes of goods well supplied.

SHEEP MANAGEMENT.

A PURPOSE and plan in sheep management is as important as it is in anything else. Even in breeding we have to calculate ways and means, and to look forward to a due provision of food for lambs as well as ewes. It is a sound rule of practice never to purchase food that can be produced upon the farm, unless a positive saving upon purchased food is possible. That this has been so with Oats during the last year or two appears clear enough, and yet the matter is well worth looking into. It would seem that while imported Oats can be had in any quantity at the wholesale rate of 1s. 6d. to 2s. per bushel, it surely answers best to purchase what we require for the sheep, and turn the land to better account in the cultivation of Barley and Wheat. But does it? Under ordinary culture the yield of Oats per acre does not exceed 40 bushels, yet we know full well that under high culture three times that quantity can be grown, and the quality of superior home-grown Oats is greatly above that of so-called cheap imported Oats. Of course we admit that 120 bushels per acre is an extraordinary crop, but there is no doubt that such crops of Black Tartarian Oats have been grown, simply by superior cultivation. The reason for the wide difference in the yield of Oats is a question of fertility of soil. The absurd old plan of applying a moderate dressing of manure for Wheat, and subsequently taking two or three other crops without any manure, is still in force upon many a farm, and crops inferior both in quantity and quality are the result; in common fairness such results cannot be taken for comparison. Weight is a good test of quality in Oats, 42 lbs. per imperial bushel being the recognised weight of really useful corn. This is the standard buying weight of the East Anglian farmer, who does not care to purchase Oats under 12 stone of 14 lbs. per coomb of 4 bushels. Fine home-grown Oats will often closely approach 50 lbs. per imperial bushel, and they are worth from a third to a half more than most imported Oats. We have dwelt somewhat upon the question of home-grown *versus* foreign Oats here, because this corn is such an important article of diet for sheep.

Under ordinary conditions Oats have the preference over other corn for sheep feeding, simply because Wheat and Barley can be turned to better—that is to say, more profitable account. At the present time inferior Barley that is not worth more than from 20s. to 24s. per quarter, is being crushed or ground and mixed with other food for fattening sheep. In his experiments in sheep feeding at Woburn, Dr. Voelcker tried five pens, each containing eight sheep, the corn used being crushed Oats, griddled Barley, Oats and Barley in equal quantities, Wheat (whole), Oats and Wheat in equal quantities, respectively in the different pens. About 20 lbs. of sliced Swedes and a quarter of hay chaff was given with about three-quarter lb. of corn per head daily, and Dr. Voelcker says "The results show, in the case of four of the five foods, comparatively small differences in the increase of live weight. The actually highest result was got with Wheat, but both Oats and Oats with Barley nearly approached it, whilst Barley given alone showed a less favourable result, and Wheat with Oats the lowest of all. It would appear that between foods so nearly approaching one another in chemical composition as these, the differences in live weight obtained are likely to be but small, but that the mixture of Oats and Wheat is not so suitable, whilst as to the rest, Barley given alone is hardly as good a food as the others. As regards Wheat, the experiment proves, I think, now, beyond doubt, that this may be both safely and profitably used for feeding sheep off

on roots. For the third year in succession Wheat has been tried, and each time has shown good results."

The practical outcome of these experiments is, that while giving the preference to Oats, Wheat or Barley may be used with safety always, and with advantage when prices fall so low for either sort of corn as to prove unremunerative. They go also to support our oft repeated advice always to use home-grown corn in preference to purchased linseed or other cake, which may be pure, but is probably adulterated. We used regularly to give sheep hay and hay chaff, but finding them to eat with equal relish chaffed Oat, Barley, or Pea straw, we have for some time refrained from using hay for sheep, and no farmer will go far wrong who uses about a pound of crushed corn with a moderate quantity of roots, and as much chaff or whole straw as the sheep can consume.

(To be continued.)

WORK ON THE HOME FARM.

Never had we such heavy arrears of ploughing as at the present time, and the delivery of corn sold still retards that work. We should, of course, much prefer to push on ploughing and leave the corn till the new year, when we shall probably have frost and snow to put a stop to work on land. Unfortunately we cannot do so, but what time can be given to ploughing is turned to best account. Of corn threshed the yield is on the whole satisfactory, Barley being about 50 bushels an acre and Wheat about 40. Some of the heavy land Wheat does not approach this average, and the grain is both small and light, owing to the very dull, wet, cold weather when the Wheat was in flower and subsequently. This inferior Wheat is not worth more than 30s. per quarter, yet we are glad to say our white Wheat is worth from 6s. to 8s. more per quarter. But it is the Barley trade about which there is such a sad outcry now, for most of it was so much discoloured by rain before harvest that really good malting samples are few and far between. Size and weight of grain tell more than usual in the sale of Barley. One of our tenant farmers has only realised 22s. 6d. per quarter. We have had to sell at a variety of prices ranging from 32s. downwards to 24s. per quarter, and are fortunate in having a heavy crop generally. Truly the farmers' work is handicapped by weather; we may arrange our plans with the greatest care, and leave nothing undone in our power to ensure success, but adverse weather, while it may not bring actual defeat, may prevent us from obtaining a full measure of success; and there can be no doubt that this is very generally the case this year. We are using a large quantity of discoloured Barley for pigs now, and they certainly thrive upon it; we thus turn the inferior corn to best account, and provide a certain quantity of manure for root crops next season. So far the whole of the pigs are healthy, and the sales of the more forward have been very satisfactory.

SEEDSMEN AT THE SMITHFIELD SHOW.

THE Cattle Carnival at the Agricultural Hall is an event of far-reaching importance in the world of agriculture, and the farming element finds its way in strong force to "Merrie Islington" during the course of the great Show. Long prize lists in the daily papers, and descriptive notes, have exhausted all that there is of interest in the live stock exhibits; but a feature of interest both to farmers and gardeners—namely, the stands of the great seed firms—have not received the notice that they undoubtedly deserve. An important factor in profitable farming is the selection of the finest and most productive varieties both in corn and roots, and a distinct service to agriculture has been rendered by several firms of repute in devoting persistent attention and the best skill that experience can provide to the production of improved varieties in all staple farm crops. If improved varieties will enable five quarters of corn to be harvested where but four were secured before, a step in advance has been made, and a corresponding improvement in seed samples will lead to increased prices for an increased bulk of produce. Farmers would do well to give this matter their best attention. The able farmer and writer who endeavours week by week in the columns of the *Journal of Horticulture* to show farmers that only by a cautious yet courageous deviation from the "beaten track" can the fallen fortunes of British Agriculture be retrieved, has not hesitated to pay what many would consider "long" prices in order to convince himself that he had the best (hence most profitable) varieties that could possibly be procured. Had he not proceeded on these lines he would probably not have been able to point, as he has done in the present writer's presence, to a field, and say, "That gave me 7 quarters this year; three years ago, my first season, it yielded 3."

From the farmer's point of view the past season has not been so unfavourable as many that preceded it. Corn crops are generally good, though the harvesting proved a troublesome matter in some instances. Root crops have been heavy, and both in bulk of produce and quality of individual examples instances have been cited which equal what in sporting parlance would be termed a "best on record." For example, the enormous specimen of their new Elephant Swede, which graced the centre of Messrs. Carter & Co.'s fine stand, is claimed as the heaviest Swede produced. The weight recorded on the exhibitors' card was, without top, 30 lbs., and the girth 34 inches, or a diameter of nearly

1 foot. It was certainly a splendid root and the largest we have seen. The variety was also well represented by other examples, and is claimed as "The Swede of the future." Messrs. Carter's other useful Swedes, Green Top Hybrid and Prizewinner, and their fine Mangolds Golden Tankard (good examples grown on the estate of H.R.H. the Prince of Wales) Golden Intermediate, Warden Prize and Mammoth Long Red were exhibited in quantity. A portion of the stand was devoted to pasture Grasses in growth, another to Potatoes, while a series of arched recesses was devoted to samples of garden and farm seeds clearly labelled. Altogether it was a stand full of practical interest.

Dicksons, Limited, of Chester, and Harrison & Son of Leicester were represented, the former by grasses, fruit, fruit trees, &c., the latter by a good display of roots and garden seeds. Messrs. Oakshott & Millard of Reading had a very creditable display of roots "grown by their customers under ordinary field cultivation." These included examples of the Defiance Mangold grown on the estate of the Earl of Warwick, and stated to have produced 60 tons per acre; the Premier Purple-top Swede, Mammoth Long Red Mangold, and various Turnips. Seed corns and Potatoes were also shown, amongst the latter the round variety Satisfaction (by the way, are there not two "Satisfactions" in the field?), which last year, the exhibitors state, "produced upwards of 13 tons per acre," presumably under "ordinary field cultivation." "Satisfaction" in this case is well named.

A large, varied, complete, and highly interesting stand was that arranged by Messrs. Sutton & Sons, whose name is a household word both in the farm and garden. The front was furnished with glass cases, containing specimens of useful grasses and useless, or worse than useless, weeds, each fully named and described. The inclusion of the latter is a wise proceeding, for the bad should be known as well as the good. Natural grasses in substantial bundles—like miniature sheaves—and samples of grass seeds were a great feature. Amongst the roots large piles of Sutton's Stubble and Champion Swedes, Golden Tankard, Berkshire Prize, Mammoth, Intermediate, Oxheart, and other Mangolds were conspicuous. Green Globe, Mammoth, Greystone, and other useful field Turnips were also noteworthy. Baskets of Potatoes, comprising the majority of Messrs. Sutton's excellent introductions, and their New Intermediate Carrot, which has won innumerable prizes and is becoming popular in the markets, were other features of this interesting and instructive stand.

Roots were the main feature of Messrs. Webb's stand, and the display was typical of the advance that is being made by the Worcestershire firm. The Champion Yellow Globe Mangold, of which a weight of 58 tons, 18 cwt., 2 qrs., and 5 lbs., has been recorded per acre; Imperial Swede, of which a weight per acre of 37 tons, 2 qrs., and 24 lbs. has been recorded; Invincible Turnip, Yellow-fleshed Tankard Mangold, and new Giant King Swede were shown in large piles. Well worthy of attention, too, were the seed corns, Golden Grain Barley, Challenge Wheat, Kinver Giant Wheat, and Black Tartarian Oats—worthiest of all the firm's fine Barley Kinver "Chevalier"—*sans peur et sans reproche*. Stourbridge Glory, Wordsley Pride, and other good Potatoes were noteworthy.

We believe visitors are not allowed to take their canine friends into the Show—a fortunate thing for Spratts Limited, or the array of dog comestibles set forth on their stand would lead to its speedy demolition by a tempted legion of hungry animals.

OUR LETTER BOX.

Rape Cake v. Wireworm (*F. G.*).—Do not place reliance on the statement that wireworms will kill themselves by eating rape cake to repletion. A gentleman anxious to satisfy himself on the point collected some wireworms, and put them in a barrel with a generous allowance of cake. They appeared to be exactly suited by the incarceration, and increased rapidly in strength and numbers.

REMARKS.

2nd.—Generally fine with some sunshine, but one or two slight showers.

3rd.—Fine with some sunshine; strong wind.

4th.—Dull and damp early, fine bright day, damp evening.

5th.—Fine, but generally cloudy, very mild.

6th.—Fair day with some sunshine; high fog at times in afternoon.

7th.—Fine and bright, with seasonable temperature.

8th.—Foggy till 11 A.M., then overcast, and steady rain from 3 P.M. to 9 P.M.

An exceptionally mild and generally fine week. Mean temperature about 7° above the average.—G. J. SYMONS.

CHRISTMAS POSSIBILITIES.

ONCE more the greatest of all festivals is approaching, and preparations are already in progress for celebrating it in a befitting manner. Christmastide is essentially a period of joyousness. That it is too often a time of extravagant roystering we all know; but the abuse of what is good is unfortunately prevalent in many things, and all we have to say on that subject is this—Let mirth be wholesome and seemly throughout the festive week, so that there may be no after regrets, but, on the contrary, pleasant memories. That the overwhelming majority of our readers need no hints of guidance from us we well know; but we also know, as all are aware, the young and the sanguine are liable to be tempted beyond the lines of prudence, and to jeopardise their good name by a false step thoughtlessly taken. This has happened in the past with serious results, and we would not that any young gardener should fail in his duty when his associates are, for the time, free from responsibility, nor shall he if any words of ours can have a restraining influence.

Relaxation from toil and social pleasures are incidents of the season, and these in turn are tests of character. When personal inclinations come in conflict with stern duties, the weak and careless fall; the strong display their strength in rising superior to the allurements of the moment, and become trusted helpers, winning for themselves claims to advancement and more responsible positions. Christmas time, hence, is often a testing time, and our wish is that every young reader of these notes will pass through it manfully and honourably, so that his services may be the more prized accordingly.

Christmas time, while it brings pleasure to many, also brings labour to some—to most who are engaged in gardens. More than ordinary wants have to be met, and extra efforts made to meet them. Well it is for those, and we are glad to believe they are in the great majority, whose cheerfulness and pleasure increase with the activity they display in contributing to the happiness of others. The possession of this admirable spirit of willingness, though, does not wholly depend on those who labour, but is encouraged, or the reverse, by those who enjoy the fruits of such labours. And here comes in the enormous power of considerate kindness on the part of those who are served. It is as easy to request a service pleasantly as to order it severely, and there is no doubt as to which method brings the readier response. It is not so much masters who need a reminder of this as some servants with servants under them. The habit of "driving" is not quite extinct, and it will not be worse for the contentment of individuals, or for their interests, if the year nearing its close brings that habit a year nearer its termination. The man who is engaged to serve, and will not do so except under compulsion, is entirely out of place in a garden, and should be advised to seek some other occupation where strict lines of discipline are laid down in ordinary routine, and if he cannot conform to them he must pay the penalty he thereby incurs. Willingness is a valuable trait in men who are, or aspire to be, gardeners; and those of them who have the happiest lives are those who have the aptitude of anticipating wishes, and the more successful they are in this, the less, of necessity, are causes for complaint. It is not possible to cut the ground from under the feet of habitual grumblers, but even fault-finding may be made somewhat of a task, and that brings a little consolation.

Gardeners old and young may be closely pressed during the present week, and each should strive to assist the other. Without the produce of gardens, churches, halls, and tables could not be adequately furnished for the festival. The best that is possible is demanded on the occasion of family reunions and the assembling of friends, while the contents of many a garden will be displayed in churches; and it is only natural when the decoration of sacred edifices is practised in accordance with ancient custom and modern taste, that those who take active interest in the work should desire that only what is worthy and good of its kind should be presented there. It is no doubt a great tax on many gardeners to meet the requirements for the purpose in question, and at least in some instances they could be limited, not only without prejudice but with advantage, for exuberance in decoration suggests ideas of extravagance, not to say waste, that are obviously inappropriate under the circumstances.

How greatly the resources of gardens, developed by the skill of cultivators, contribute to home enjoyments will be manifest, not in great mansions only, but in residences of lesser note during the present week. Efforts are made to keep the best fruits for Christmas, the finest of Apples and Pears that can be had in season, the noblest bunches of Grapes, and whatever else may be provided for the occasion. No doubt disappointments are incurred in this matter which are not more keenly felt by the owners of fruit than by those whose duty it is to preserve special samples for special times and purposes, but fail almost at the last moment. Gardeners may arrest or retard the shrivelling or decomposition of fruit, and advance the ripening of some good kinds, but there is a limit to their power, and strive how they may they cannot always succeed in the object they may have in view. Some seasons are much more favourable to the keeping of fruit than others, and this is certainly not one of the best of them, but rather one of the worst.

Plants and flowers, too, are more than ever in demand in making rooms bright and cheerful on festive occasions, and where adequate means are afforded there is no lack of men capable of maintaining a supply at all times, with an extra abundance periodically by special preparations; but flowers cannot be had in the absence of the conditions necessary for their production and preservation. This may appear a mere truism. It may be that, but there is, perhaps, more in the observation than appears on the surface, or than all who are interested comprehend at a glance. For instance, gardeners with a limited number of glass structures in their charge may have had many more flowers last Christmas than they have this, yet there has been no reduction in means. Though there may be the same area of glass, the same number of plants grown as before, with no difference in their treatment, there is a marked difference in the result. Many persons cannot understand why that should be so, nor is it to be wondered at. The cultural conveniences may be the same, but the conditions—the natural conditions—are not the same, and therein rests the sequel of success in one year on a given date, and comparative failure in the year succeeding. A supply of flowers at Christmas depends as much on retarding and preserving as on forcing and advancing; indeed, in many, and probably the great majority of cases, the former process is by far the more important, and in not a few the only one that is practicable.

The present autumn has been no more favourable for the keeping of flowers than of fruit. Both have "gone off" prematurely through the same causes, and these are mainly two—the succulent nature of the growth in consequence of a wet dull season, too much rain and not sufficient sun; and long mild periods during the autumn, followed by sudden and extreme falls of temperature, causing the moisture in the air to be condensed on, and by the suddenly cooled petals, decay following. These are the conditions that have operated in the ruin of thousands of Chrysanthemum blooms weeks before their time, and it is, and must be, the same

with other flowers grown under the same circumstances. The natural result is this, and being natural it is inevitable, where the Christmas supply of flowers depended on retardation and preservation there must be scarcity this year in most, if not all, green-houses. Where suitable houses for advancing other flowers exist gardeners who were wideawake would see the blank in prospect and take prompt action for diminishing the inconvenience.

Vegetables of all the useful and seasonable kinds are plentiful this year where space was adequate for their production, and proper methods, which have been indicated, pursued in their cultivation.

With these remarks, penned with the object of minimising discomforts that may be felt through possible, and in many instances unpreventable shortcomings, we wish to all our readers of every rank and degree most cordially and sincerely

A MERRY CHRISTMAS.

HISTORICAL NOTES ON ORCHARDS.

It is a trite old saying that "history repeats itself," and the observation is not destitute of truth. In respect to the culture of fruit, we find history repeating itself with a considerable amount of fidelity. Relative to the planting of orchards in past times we find this sentence in the notes published last week, and which were written before many present-day readers were born. Remarking on the decrepit orchards it is stated, "no regular systematic planting and successive cultivation of fruit trees seems ever to have been kept up in this country; whatever was done was brought about by urgency, and carried out with impetuosity, but no steady, continuous system of operation; and hence the state in which our orchards were at the close of the last century." Let it be added, hence their state at the beginning of the present decade; indeed, hence the condition of the great majority now.

Something like regular and systematic planting has, no doubt, been practised in private gardens for affording fruit for private use, and adding to the number of varieties in existing collections, for there is a natural desire on the part of gardeners and owners of gardens to "try new sorts." A great deal might be said in favour of this. Information is derived thereby, and the most profitable varieties determined in the districts of these private garden experiments that may be of service to the surrounding community. Besides, home interest attaches to such trials, and pleasure is derivable from them, not less than that obtained from growing a variety of flowers by persons whose tastes lie in that direction; and if gardens are made really pleasurable the end attained justifies the means.

The above citation does not, however, refer to garden fruit for private use, but to extensive orcharding, or fruit farming, for commercial purposes. In that respect history has unquestionably repeated itself during the present generation; for whatever of planting has been done during the last three decades has been by fits and starts, or "brought about by urgency, and carried out with impetuosity." There is no wonder that very much alive Americans, who have been in the habit of prospecting this country with their eyes open for years, should not have seen their opportunity, and seized it, by planting extensively, and sending more marketable fruit to the "old country," than they saw was produced and sold in it. Who can reasonably quarrel with them for doing so? The fault that the English Apple supply has been so inadequate, not in quantity so much as in quality, is not theirs, but the direct outcome of the negligence or apathy of English landowners and cultivators. Granting the "law" has prohibited planting in some cases, have those whom the law has not obstructed done what might have been done in providing English fruit of the first condition and in large bulk for our markets? No one can answer in the affirmative. Granted that extraordinary tithe, railway rates, market tolls, and middlemen's charges are impediments to fruit production, what have been the efforts to remove them? There have been practically no systematic organised and persistent efforts to that end. "Papers have been read" on the subjects during recent years, and speeches made by able men at "meetings;" but what care Ecclesiastical Commissioners, railway directors, and market owners for "papers" and "discussions," which end where they began? and what is the use of organisations that begin and end with "papers?"

The periodical agitations that spring up, and subside again, no doubt lead to spasmodic planting. Something calls them forth—some kind of "urgency," an impetuous rush for trees following. The "urgency" for systematic, continuous, and successive planting of trees in this country was never so great as it is now, and if not

pursued the Apple trade will soon be practically driven out of the kingdom, so far as regards the production of the fruit. There are signs, however, that the reaction that set in, with the Chiswick Congress of 1883, in favour of an extension of orcharding will not quickly subside, for if the Royal Horticultural Society slackens its efforts in the direction indicated, other agencies will carry out the work, and ought to do so, because experience is proving that the best English Apples quite surpass transatlantic fruit in culinary virtues, and it is only a question of time for the general body of consumers to find it out. But it has to be remembered their first lessons in the education desired will be through the eye, therefore it is very essential that the appearance of samples be good and even tempting, for it is not in human nature to hasten to taste that which is not pleasant to see. It is that fact which the most formidable competitions in the fruit supply have recognised, hence the position they have gained in our markets. After this long introduction to our old friend's writings, we shall have to be content with a small instalment of them this week, reserving the completion for another occasion. Here is his continuation:—

"Having exhibited the low condition of orchards, and the almost total extinction that had befallen those in Kent at the close of the last century, we remarked that the observations we were about to make with respect to Kent would apply equally to the orchards in other parts of the country; and as a proof we find about the same time the late Mr. T. A. Knight was devoting his time and influence to the resuscitation of those of Herefordshire, which had fallen pretty much into the same declining state.

"We have no means of judging, but in the absence of positive evidence on the subject we have every reason to believe that in consequence of the gradual decrease of the home supply the importations of foreign fruit must at that period have been considerable; and so again we are brought to a crisis similar to that with which Richard Harris had to contend nearly 300 years before. We are warranted in stating this supposition, for no sooner had we entered on that long and disastrous war, which raged from 1802 till 1815, during which time our commercial intercourse with the Continent was cut off, and our importations were either considerably restricted or entirely stopped, than the price of fruit rose to an enormous height. But till then men had forgotten all about their orchards, and it was not till "the pressure from without," and the old urgency were brought to bear upon them, that they bethought themselves of the old trees and the old orchards which they had neglected and thrown away years before, and all at once they began to wish them back again. Numerous, doubtless, were the regrets and self-reproaches which many a one expressed when his neighbours returned from Covent Garden or old Fleet Market, rejoicing over the five golden guineas they had got in exchange for a bushel of Apples. Many were the grave councils held across boundary fences of adjoining farms, and weighty were the sage remarks that met with ready acquiescence at market-rooms on market days and church doors on Sundays; and then, after each and all had talked themselves into the assurance that no doubt could exist as to the remuneration to be obtained, they set to work with all possible rapidity, liberality, and hope to redeem lost time by planting orchards, which some seven or eight or ten years afterwards might come into bearing—for there were no dwarf orchards in Kent in those days.

"The high prices continued. Those who had a supply congratulated themselves on their good fortune or good judgment, and those who had none grumbled because they had neither. Thus matters went on with the usual attendants of complaint, disappointment, or dissatisfaction till the conclusion of the war, and then in 1816 there was an importation of foreign fruit. The protecting duty at this time was 3s. 2d. a bushel; but this was not enough, and great was the outcry against such importation being permitted. Memorials were prepared, signed, and presented for an increase of duty. Orchards were again to be grubbed up which had only a few years before been planted. Families were to be ruined, parishes depopulated, and the country sacrificed because the orchardist could not realise "war prices" for his fruit, and because the consumer was enjoying his apple-dumpling twice a week instead of once, as before. The outcry succeeded, and because the price of Apples had fallen one-third Government raised the protecting duty from 3s. 2d. to 4s. in 1819. This was a great deliverance, and so the work of planting progressed to such an extent that where there was an acre planted in 1802 there were ten planted in 1819. Still, notwithstanding the increased duty, there were 92,212 bushels imported that same year. Planting increased; Apples realised from 6s. to 8s. per bushel, and fruit became again one of the most important articles of produce in all the county of Kent.

"A tabular view is subjoined of the quantities of Apples imported into this country from 1819 to 1837, a few months before

the 4s. duty ceased, and also the average prices of English Apples at Covent Garden in each year."

Year.	Duty.	Quantity imported.	Average price at Covent Garden.	Year.	Duty.	Quantity imported.	Average price at Covent Garden.
	s. d.	Bu-bels.	s. d.		s. d.	Bu-bels.	s. d.
1819	4 0	92,212	not known	1829	4 0	31,093	3 0
1820	4 0	45,324	not known	1830	4 0	22,462	5 6
1821	4 0	80,887	8 0	1831	4 0	52,615	6 0
1822	4 0	45,830	8 6	1832	4 0	16,537	3 6
1823	4 0	31,123	7 0	1833	4 0	27,087	3 6
1824	4 0	68,758	6 9	1834	4 0	18,447	3 4
1825	4 0	68,304	8 0	1835	4 0	11,574	3 0
1826	4 0	40,865	7 6	1836	4 0	14,859	3 6
1827	4 0	28,670	4 6	1837	4 0	20,502	2 3
1828	4 0	48,202	5 6				

It will be seen from the above table that there was on the whole a steady reduction in the importation, after the additional 10d. a bushel duty was imposed. There are one or two exceptions, the consequence probably of the partial failure of continental crops; but it will be further observed that though the importations decreased so did the prices for English fruit. It is also noticeable that with only about two exceptions in nineteen years, the greater, relatively, the importations of foreign Apples, the higher the prices in Covent Garden Market. The figures we are informed were taken from a Government Blue Book, prepared for the purpose of the Parliamentary inquiry, and may therefore be taken as accurate. This result will be not a little surprising to some of our readers, and each must solve the problem in the best way he can. We make no attempt to do so at present, but simply publish what appear the facts of the case as they are placed before us. The reduction of the 4s. duty to 6d. and its influence on importations and prices will next be referred to.

HARDY CYCLAMENS.

BEAUTIFUL as are the improved varieties of the Persian or greenhouse Cyclamens, the hardy gems of the border and rockery should not be neglected, yet nowadays very little is written about them.

The common Cyclamen grows wild on the hill sides of the south of Europe, and is so plentiful that the pigs feed upon the roots or bulbs—hence our English name, Sowbread. The C. Coum is found at a considerable elevation on the Alps, where it is protected from the severe frost by the snow. When the warm days of spring partially melt the snow this little plant may be seen with its beautiful deep pink blossom peeping through the white robe of the earth. Thus hardy are the Cyclamens, and yet how many fail to grow and flower them well.

All the species must be propagated by seed. The corms are solid—that is, they have no coats like the Onion or the Hyacinth, and they do not send forth any offsets like the Crocus or the Gladiolus. The seed is very perishable, and will not grow if kept long; hence it must be sown as soon as it is ripe, which may be known by its changing colour and bursting the seed vessel. Sow it thinly in a wide shallow pot or pan, covering it about a quarter of an inch; give a gentle watering, and place the pan in a cool frame. Keep the soil moderately moist by sprinkling it occasionally with water from a fine-rosed watering pot. By no means flood it, or pour the water on heavily, for if that is practised the seed will be washed bare and perish. Some of them may germinate, but the greater part will remain under the soil till the spring. In this position they should remain until all grow, and then increase the quantity of water, but only just sufficient to thoroughly moisten it, withholding it then until the soil is moderately dry again.

The beautiful seed leaves will increase in size during the growing season, and each will form a small bulb. Towards the end of June the leaves will begin to turn brown and decay, then they must be allowed to go to rest by giving no more water. Keep them in the pan, placing it in a cool place so contrived that no heavy rains can fall upon it. Towards the autumn they will begin to grow again, and as soon as that is observed stir the surface of the soil, clearing it of moss and lichens or weeds. Then put a thin coating of fresh soil on the surface, and water it to settle it close upon the small bulbs, which should not be covered too deep. I prefer keeping the young corms the second year in the same pan, because the first season they are so very small that there is danger of a considerable number being lost if the attempt is made to transplant them or take them up when a year old. Keep the soil, during the second season, properly moistened, and when the leaves decay allow them again to go to rest. When the season of growth arrives, then keep

a watch upon them, and as soon as the least signs of growth are apparent provide a sufficient number of thumb pots, the smallest size made, drain them well, and fill them with the compost, then carefully, with a flat sharp stick, take up a bulb and place it in the middle of the pot, leaving the upper part of it just above the soil. If there are any living roots, preserve, if possible, every one of them. When all are potted give a good watering, and place the pots upon a thick bed of coal ashes in a cool frame. Protect them during the winter from frost, giving air on all favourable occasions. Towards spring they will have made three or four leaves, and the pots will be found full of roots. A shift into a larger sized pot will then be necessary, and will encourage the corms to increase in size very materially. I have shifted them twice in the season with the best effect. By this close attention to repotting, and a due supply of water, the plants will have increased to such a size that many of them will flower; and, in such species as are apt to sport, will reward the cultivator very probably with some improved varieties. They can be either grown in pots subsequently or planted out.—T. A. B.

CANKER IN FRUIT TREES.

I AM obliged to Mr. Kruse for the exceptions he has taken to my reply to his letter, as they give me the opportunity of making more clear some points of the theory suggested by me as to the cause of canker. If this theory is correct the disease is due, not to the presence of anything injurious in the soil, but to deficiency of one or more of the elements of plant food necessary for perfect growth. In the case of the Apple tree, as an unusual quantity of soda is contained in the fruit and of lime in the wood, it is reasonable to infer that a deficiency of one or both in certain soils may affect the nutrition of the tree and be the cause of canker. But however necessary soda and lime may be to the welfare of the Apple, there are other constituents, such as potash, magnesia, iron, and phosphorus, which in certain proportions are equally necessary. The absence of any one of these may induce that condition of the tree which favours the development of canker. When a manure is to be applied with the object of restoring a cankered tree to health, I recommend that it should contain all the above-mentioned ingredients together with a source of nitrogen. It may be that from the composition of the soil one or more of these are unnecessary, but as there are no ready means of ascertaining what are actually required it is better to be on the safe side and apply all, more especially as the superabundance will not be injurious nor entail loss, but on the contrary prolong the fertility of the soil.

Mr. Kruse complains that my statements are general while his were particular. It was not possible for me, with imperfect information of his case, to deal with it other than generally. He now supplements his information as to the iron contained in his soil by stating that Dr. Voelcker's analysis was of the top sod only, and that underneath this there is a thick layer of "red pin." This, I presume is a local name for a hard deposit of sand, gravel, or clay, heavily charged with iron oxide, sometimes called hard pan. This condition of soil and subsoil with the existence of canker in Apple trees is not inconsistent with my suggestion, that the disease is not caused by the iron in the soil. The soil over the "hard pan" may be deficient in one or more of the necessary constituents, and if it be shallow it would sooner become exhausted, and the trees, according to my theory, cankered quite independently of the action of the iron.

The case as stated proves, not that the canker is in any way due to the presence of iron, but only that it is coincident with it. It would be profitless to discuss the question further without fuller particulars as to the geological formation and the local circumstances of the particular district. There may be very good reasons why the soil lying directly on the ragstone rock is more fertile than that lying on the "hard pan," which have no relation to the comparative quantity of iron present. Mr. Kruse's statement that dung and such manures as furnish humus are better for trees, because "they dissolve the iron in the soil," is scarcely consistent with his idea that the iron is the cause of the mischief, for iron, if injurious, must be so in direct proportion to its solubility, as it can only act on or be assimilated by the plant when in a soluble condition.

My experience leads me to prefer for the growth of fruit and other trees, especially Roses, a pure loam, any deficiencies in which can readily be supplied by dressings of manures containing what the trees require, and I believe that no form for that purpose is so convenient and economical as what is commonly known as artificial manure. The composition of humus is uncertain. It is a black substance, the result of vegetable decomposition, of which bog earth is an example, and is insoluble in water. It is principally composed of carbon, combined with oxygen and hydrogen. It

may, under certain circumstances by its power of absorption, help to maintain humidity in the soil, fix the ammonia, and assist the solution of calcic carbonate; but Liebig, Ville, and other great authorities agree that it contains no nutritive elements which can be assimilated by the plant, therefore it is very improbable that those manures which make humus are the best for fruit trees.—EDMUND TONKS, *Packwood, Knowle.*

ODONTOGLOSSUM EUGENES.

IN a recent issue of the "Orchid Album" illustrations are given of *Cattleya Gaskelliana alba*, *Calanthe masuca*, *Disa racemosa*, and the *Odontoglossum* named above, which is a particularly beautiful addition to the numerous hybrids. Mr. Williams thus writes concerning it:—

"*Odontoglossum* has become both an extensive and a very important genus of the Orchidaceæ. The European travellers and plant collectors are continually sending home fresh stock, the result of their labours in various parts of the mountain regions of South America, and as it is now so well understood by growers of Orchids at home that these *Odontoglossums* are purely mountain plants, the treatment they receive on their arrival in this country is so thoroughly congenial that we have succeeded in enlarging the genus to a very great extent with hybrid forms, which have added considerably to the embellishment of every Orchid house in the country. These natural hybrids have been brought about through insect agency, and the great majority of them are welcome additions to our collections. Such is the case with the plant whose portrait is here given, which was introduced by Messrs. Veitch and Sons of Chelsea, and flowered for the first time in this country in the garden of His Grace the Duke of Sutherland at Trentham. It is a very handsome hybrid, and its parents are supposed to have been *Odontoglossum Pescatorei* and *O. triumphans*. In general habit of growth it most resembles the first-named plant, but its flowers partake more of the character of *O. triumphans*. We are heartily glad to find so many natural hybrids are being discovered in their native wilds, for notwithstanding the skill and energy of our hybridisers at home, very little success has attended their labours with this genus; but we hope soon to see this difficulty overcome, for there is doubtless a great future yet in store for the numerous admirers of the *Odontoglossums*. The most forward seedling *Odontoglossums* we have yet seen are in the garden of H. J. Buchan, Esq., of Wilton House, Southampton, raised by his gardener, Mr. Osborne.

"*Odontoglossum eugenes* is a magnificent evergreen plant, with bright green foliage; the inflorescence is arched and many-flowered, producing a grand effect when the blossoms are expanded. The flowers are 4 inches across, and of a bright, showy, and pleasing colour; the sepals and petals are of a pale yellow, distinctly margined and tipped with deep yellow, the centre and base of the petals white, both sepals and petals being heavily blotched with chestnut-brown; lip white, with yellow crest, and a large blotch of chestnut-brown in the centre, while the column is white. This plant flowers during the months of June and July, and lasts in full perfection for six weeks. The length of time *Odontoglossums* retain their beauty renders the flowers of these plants so valuable; moreover, we have frequently observed that the flowers of those kinds which open during the dull heavy days of winter and early spring do not suffer from the fogs—which we often experience at that season of the year—in the manner that many other orchidaceous plants suffer, so that this is another favourable argument for the cultivation of the various members of this truly beautiful genus.

"This plant requires to be treated in precisely the same manner as its supposed parents. It should be grown in a cool house, and shaded from the hottest sun in summer, but in the autumn and winter shading may be entirely dispensed with. In the spring, when the sun begins to rise high and shine powerfully, will be soon enough to think of shading the *Odontoglossums*; but, as we have frequently remarked, these plants should never be shaded after the sun is on the decline on a summer afternoon, because we cannot in this country expose them to a greater share of light than they enjoy, and there is little doubt this thorough exposure is one of the great secrets in the successful management of Orchids. Treated in this manner the plants form fine growths, and ripen up

their bulbs thoroughly, from which fine spikes may be reasonably expected, and fine spikes produce fine flowers. On the other hand, weak growths cannot be expected to produce like results, but must lead to failure and disappointment."

ANGRÆCUM SESQUIPEDALE.

AT Witton Park, near Blackburn, the country home of General Fielding, there is a fine specimen of the above named grand Orchid in full beauty. The plant, I understand, has been one of the principal attractions of Witton Park for many seasons, but this year it is better than ever, there being no less than seventeen of its peculiar though beautiful flowers. It is intended, I believe, to have the specimen photographed. Mr. Blench, the gardener, evidently understands the requirements of this Orchid.—VISITOR.

GRAPES SCALDING.

I AM much obliged to "J. B." for submitting for my consideration a case of scalding very similar to that given by the Editor in answer to a communication of Mr. Simpson's on page 392. The Editor there says, "The subject of Grapes scalding is neither exhausted nor settled," and I cordially agree with him. He goes on to say, "We have known houses of Lady Downe's Grapes in which scalding is practically unknown, and also a house of Black Hamburgs in which it was not possible to prevent the fruit of one Vine scalding by any method of ventilation, while not one injured berry was seen on the other Vines in the same house." For all practical purposes the two cases—this one, and the one given by "J. B." on page 517—are the same, only it is unfortunate perhaps that the Editor's Vines were not Lady Downe's instead of Black Hamburg. But these are by no means solitary cases. For some years I had the charge of a span-roofed house running north and south, 40 to 50 feet long and 12 to 13 feet wide, planted with Lady Downe's with the exception of one Vine, and that an Alicante. This Vine filled three lights on each side of the house, and always carried the finest Grapes; but they were scalded every season, or nearly every season, while not a berry of Lady Downe's was affected. The Vine of Alicante was at the north end of the house. Ventilators on each side at the base could be opened, and also at the top on the west side. To try and prevent scalding taking place ventilators were arranged as well on the east side, but the Alicante scalded as badly as before.

I am rather surprised that "J. B." did not submit this difficult matter to those who have been so ready to condemn my contributions on Grape-scalding. The fact that two other varieties than Lady Downe's have scalded under similar conditions, as far as appearances are concerned, at least, strikes at the very root of the constitutional theory. It goes further, and helps to prove that Lady Downe's amongst Grapes cannot be regarded as the sole variety liable to scald. It proves more than this, that scalding is not alone due to defective ventilation, although I believe it more generally arises from that than any other cause. I advanced over-feeding, which I have had ample proof to convince me that it is another cause, and one that will end as disastrously with the Vines, whether Black Hamburg or Lady Downe's, during that critical period as with the Peach or Nectarine. I also believed in other causes, and perhaps some of the solitary instances of scalding given above may be traced to one or other of them. I believe at that critical period that any check to the Vine, whether arising from inactivity of the roots, dryness, overfeeding, or an insufficient supply of food in the border that the Vine might require just then, would bring about scalding.

It is very difficult matter for anyone to state the exact cause of scalding in any of the three cases given above. To do this it is necessary to be on the spot and investigate the case carefully, and even then it might take a long time to trace the evil to its true source. In the case of the Alicante, the cause was dryness at the root, which was found by accident. The Vine had grown straight out of the house, through a walk and into a small bed planted with Lily of the Valley, through one end of which hot-water pipes passed. The Vine flagged, and watering the border inside had no effect in restoring it. It recovered at night, and the leaves drooped daily for a week or more during the daytime. The weather being very dry we soaked the Lily bed with liquid from a cesspool, which gave new life and vigour to the Vine. By attention to the watering of this Lily bed afterwards scalding was unknown in the house as long as the Vines occupied it.

Your correspondent, Mr. J. B. Riding, on page 470, states that he has not ventured an opinion as to the cause of scalding. Without going back, I think he once before reminded us of this. It appears, therefore, that he has made a mistake in imputing to me a modesty that he possesses in a marked degree. It is evident he has been too modest to give us his opinion on the cause of

scalding, but, now that he has been invited to do so, we may look forward with interest.—WM. BARDNEY.

THE NATIONAL AURICULA AND CARNATION AND PICOTEE SOCIETIES.—DECEMBER 14TH, 1888.

Is it not a somewhat unusual proceeding to report the minutes of the committee of any society unless by authority of its officers? An annual meeting is a different matter, being open to all, and I think it is a pity that the notice of the last Committee meeting should have been inserted, as it is inaccurate both in its statements and omissions. The statement that a new class for yellow ground Picotees was made to include selfs is a mistake. It was to include, not selfs but Carnations, as it was felt that some of the striped flowers were as worthy of recognition as the edged ones. The balance in hand was not £40 but £30, nor had I or Mr. Douglas anything to do with it. It was to be invested by Messrs. Hibberd and Leonard. The writer omitted to state that £5 was taken off the classes for twenty-four Carnations and twenty-four Picotees, and that an additional class was made by dividing scarlet and rose-edged Picotees.—H. HONYWOOD D'OMBRAIN, *Chairman of Committees*.

[The question of reporting the transactions at committee meetings appears to us to be entirely one for committees to decide. When a report is received by us from a member of a committee, we take it for granted its publication is desired, and that is our justification for its insertion.]

DIANTHUS GLACIALIS.

A CHARMING little alpine gem, which is admirably adapted for any moderately elevated nook in a rockery, or crevices between slabs of

FIG. 62.—DIANTHUS GLACIALIS.

stone. It forms a neat compact little tuft of leaves, and produces its comparatively large rose-tinted flowers freely when the situation suits it. Some of these small alpine plants are rather fastidious and difficult to manage under cultivation, but this is not the case with *Dianthus glacialis* if care is taken to protect it from enemies and to provide a position free from stagnant moisture. The latter is essential, and more of such plants suffer from neglect in this matter than in any other respect.

MANURE AND MOISTURE.

MR. IGGULDEN'S very instructive article on Pear trees brings to light a system of feeding which is but little treated upon in gardening literature. It is a common fallacy that manure must not touch the roots of the plant which it is intended to nourish, but should only be applied as a top-dressing, this being in many cases several inches from the roots. Now in the case of young or newly planted trees the latter method is without doubt the proper way in which it should be applied; but when trees are old and showing signs of barrenness, there is nothing like baring the roots and placing it thereon, covering this with a portion of the soil

again, as stated in the article referred to above. No one who has seen the cordon wall at Marston on such an exceptionally bad Pear season as the past can doubt the soundness of Mr. Iggulden's remarks. The general evenness and quality of the fruit when I had the pleasure of seeing it on the trees during a hurried visit was remarkable. Unfortunately, the time was too short for me to inquire into many details—which I am sure would have been freely told me—so that I have read with double interest the facts about Pears.

But it is not fruit trees alone which I have seen benefited by this treatment. A successful Rose-grower was showing me his favourites several years ago, and as we walked round I could not but admire the general condition of the plants, remarking at the same time that the soil must be of the nature to suit Roses. "Quite the opposite," was the reply, as he stirred the gravel, for it was little better; "but every year I clear away the soil down to the roots, and give each one a good thickness of manure, facing it with the soil again, and you see how they like it." They liked it so well that I gave those under my charge the same treatment the next winter with such a satisfactory result that I still continue the practice.

That insufficient moisture at the roots is in a great measure the cause of many failures amongst wall trees is an opinion which I have held for some time, especially as regards Apricots, and that opinion was strengthened considerably in my run through Marston Gardens. My time was too short to note with exactness, but as nearly as I can remember, running parallel with the cordon Pears were some of the most perfect specimens of Apricot trees which I have seen—not a gap anywhere, nor a decaying branch. But on another wall, where they were under the protection of a glass coping, an occasional gap could be seen, as is so frequently the case. It is not to be inferred from this that the protected trees were neglected with water, but those which were exposed must have had it far more continuously. I have noticed that there is a greater absence of dead branches on Apricot trees than usual this year, and it seems to me that the wet has something to do with that result. Mr. Iggulden's views on this subject would, I am sure, be appreciated by many readers of the Journal.—M. D.

THE NATIONAL DAHLIA SHOW.

THE usual annual meeting of the supporters of this Exhibition took place by kind permission at the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, on the 14th inst., Mr. Harry Turner in the chair, present also—Messrs. E. Mawley, T. W. Girdlestone, W. H. Williams, J. Burrell, Geo. Harris, A. Rawlings, R. Dean, J. T. West, and H. Glascock, Hon. Secretary and Treasurer. The balance sheet showed subscriptions for the past year amounting to £59 10s. 6d., with the usual gift of £50 from the Crystal Palace Company. The expenditure amounted to £114 10s. 6d., including £103 10s. paid as prize money, and the balance was made up by a *pro rata* deduction from the prize money of the trade exhibitors in accordance with the provisions of Rule 10. The accounts were duly passed. A conversation then took place on the advisability of forming a permanent society with proper rules and regulations and a properly constituted executive. It was thought that if this step was taken several of the exhibitors who do not now subscribe to the prize fund might be willing to do so. Eventually the matter was left in the hands of the Committee. Mr. H. Glascock reported that he had received a communication from Mr. W. G. Head, on behalf of the Crystal Palace Company, to the effect that the Directors would give the same amount of money as last year towards the compilation of a prize schedule, and also supply as heretofore the necessary staging, take the entries, and print the schedule of prizes. This offer was accepted with hearty thanks to the Crystal Palace authorities, and the first Friday and Saturday in September were named as the most suitable days for the Show in 1889, subject to the approval of the Manager of the Crystal Palace.

It was resolved that for the future the Judges should be selected from the exhibitors, the amateurs to judge the traders' flowers, and *vice versa*, the luncheon to the Judges to be discontinued as a charge in the balance sheet. The schedule of prizes as offered last year was passed as that for the Show in September next. The Hon. Secretary stated that he had been in communication with the Trustees of the Turner Memorial Fund with a view of obtaining a grant for the Exhibition next year, but he had been informed that the money had been voted for the promotion of Tulip culture. Mr. Glascock intimated that owing to age and increasing infirmities he should have to relinquish the post of Hon. Secretary and Treasurer, and he proposed that Mr. T. W. Girdlestone should be elected in his stead. Mr. Girdlestone having consented, the nomination was seconded, and the election carried unanimously. A cordial vote of thanks was passed to Mr. Glascock for his past services. In revising the list of officers and Committee the name of Mr. Glascock was placed among the Vice-Presidents. The following were added to the Committee:—Messrs. W. Hapthorpe and J. Burrell, Cambridge; J. Cheal, Crawley; J. Gilbert, Ipswich; W. Holmes, Hackney; Geo. Paul, Cheshunt; T. J. Saltmarsh, Chelmsford; J. Tranter, Henley-on-Thames; and J. Walker, Thame.

The proceedings closed with a vote of thanks to the Chairman for presiding, and to the Horticultural Club for the use of the room for the meeting.

THE NATIONAL CHRYSANTHEMUM SOCIETY'S DINNER

THE large dining hall at Anderton's Hotel, Fleet Street, was crowded on the occasion of the above dinner on Thursday night last. The proceedings were most agreeable throughout, and evidently enjoyed by the company. The dinner was to have commenced at six o'clock, but time enough elapsed after that hour to take note of the Chrysanthemum lovers assembled, and, let it be asked *en passant*, Does it not speak volumes for the popularity of the President that he should have received so hearty a reception after keeping a gathering of hungry men waiting half an hour for their dinner?

The prominent officials of the Society, Messrs. Ballantine, Holmes, and Starling, all good men and true, were there, of course. So was Mr. Harman Payne, the foreign corresponding Secretary, who is working well for the Society, and is a pleasant table companion withal; Mr. George Gordon, whose capital speech will be referred to later; the Rev. W. Wilks, Secretary of the Royal Horticultural Society; Sir Lewis Pelly, Bart., M.P.; Mr. W. G. Head; Mr. E. Jukes, a popular member; Mr. Stevens of Putney; Mr. Herbst, Mr. Ironsides; Mr. Needs, West Kent Society; Mr. Blake, Mr. Lynes, Mr. Addison, Mr. John Laing, Mr. J. H. Laing, Mr. B. Wynne, Mr. A. F. Barron; three respected representatives of the house of Veitch in Messrs. T. Manning, J. Davidson, and Swift; Mr. Richard Dean, and many other "familiar faces," whose names could not be obtained—not by any means an unrepresentative assembly, but the list of absentees was woefully long. Mr. H. J. Veitch was not there, important business claiming his presence elsewhere, and Dr. Hogg had been called to the country, both sending letters of regret. Mr. J. Wright, of this Journal, was not well enough to attend. Mr. Lewis Castle's face was missed through a domestic bereavement; so was the athletic form of Mr. Edwin Molyneux, who, be it known, can wield the bat and ball as well as grow fine Chrysanthemums. Mr. Gibson was looked in vain for, and Mr. Laing, sen., Mr. Cannell, Mr. Davis, Mr. Jones, and many others well known in the Chrysanthemum world were conspicuous by their absence.

The dinner? Let it suffice to say, in the accepted phraseology, that it was "done justice to." Grace before meat was said by Mr. Wilks, and sung after meat by the quartette of vocalists—Misses Mary Belval, and Ethel Winn, Messrs. John Bartlett and Franklin Clive, who were engaged to entertain the proceedings with song.

After the usual loyal and patriotic toasts the Chairman rose to propose that of "Success to the National Chrysanthemum Society," and gave a *résumé* of the Society's operations during the past year. He would first refer to the winter Show held early in the present year at the Royal Aquarium. At the time the Exhibition was held the weather was extremely bad, but nevertheless the show was a great success and a complete surprise to them. The exhibits were everything that could be desired, and special mention ought to be made of a stand of six Japanese blooms staged by Messrs. Drover, which were of phenomenal quality, and thoroughly deserved the special certificate awarded to them. Later on the Society determined on the preparation of a Catalogue of Chrysanthemums, and aid was invited from men all over the country, the work of arrangement being entrusted to a Committee consisting of Messrs. Castle, Gordon, and Payne. They had done their work well, and the Society had awarded each a silver medal in recognition of his services. (Applause.) It had been decided that the gentlemen named should form a permanent Catalogue Committee with a view to the further improvement of the Catalogue. After commenting on the appointment of Mr. Payne, foreign corresponding Secretary, the Chairman referred to the Society's September Show this year. This, he said, was noteworthy for the fine quality of the exhibits, and in every respect worthy of the Society. Coming to the great November Show, he thought that the exhibits, which reached the extraordinary number of 504, were of the highest order. He would add that the Society now had upwards of 600 members, and forty affiliated Societies, but the subscription was very low, and without some extraneous aid they would not be able to prepare such a schedule as they had arranged. In the course of his speech, which was much applauded, the Chairman referred to a humorous report of the dinner of last year that appeared in the *Journal of Horticulture*, and hoped the "chiel who was among them taking notes" on that occasion was present on this to give them another "gem."

Mr. Ironsides proposed "The Patrons, Fellows, and Guests," remarking that these gentlemen gave very substantial help, and that their numbers ought to be largely increased. He coupled with the toast the names of Sir Lewis Pelly, Bart., M.P., and the Rev. W. Wilks. Both responded in humorous terms, the former reminding his hearers that the Chrysanthemum had been chosen by the Emperor of China as his crest before all other flowers. Mr. Wilks, responding for the Fellows, said

he did not see many present. They had been described as the mainstay of the Society, but he should like to see that mainstay bigger. The reverend gentleman, ingeniously misunderstanding the proposer of the toast, then went on to say that they had also been described as ornamental. He thought he had at times been useful, perhaps when others had not appreciated it, but he had never considered himself ornamental (Laughter). Tastes, however, differed, some preferred the incurred bloom, some the ragged Japanese. (Much laughter).

A presentation of medals having taken place—Messrs. Bradbury, Cannell, Davis & Jones, Fincham, Ironsides, Sullivan, Veitch, &c., being among the recipients—Mr. Holmes read over a list of those to whom prize money had been or would shortly be paid, the total sum being stated to approach £250. He was followed by Mr. Jukes, who proposed the toast of the "President, Vice-President, and Treasurer" in eloquent terms. Mr. Sanderson, the speaker thought, was essentially the right man in the right place. As an exhibitor of incurred blooms the President was very hard to beat, and few indeed could compare with him. Mr. Ballantine, the Vice-President, too, did a considerable amount of work for the Society in a very quiet way, and was of great help to the Secretary in the fulfilment of his onerous duties. As for the Treasurer (Mr. Starling), he had taken the reserve fund under his special care. It was his pet child, and though not large he was assiduous in pressing its claims. The Society, remarked Mr. Jukes in conclusion, was most ably served by its officers.

The President, in responding, deprecated the contribution of such important services to the Society as those attributed to him, but if he had not done much good he had at all events done his best to encourage the young. Messrs. Ballantine and Starling also responded in suitable terms, the latter remarking that although the financial position of the Society was all that could be desired, he would like to see the reserve fund larger. It now amounted to £80; he would like to leave it with £500 or £1000.

Mr. Herbst proposed the health of the Hon. Secretary, Mr. Holmes, who, he said, had by his administrative talent, energy, and force of character made the Society the most substantial in the kingdom. The interest in the Chrysanthemum had now spread all over the world. Valuable as was the work rendered to any society by its Committee, the Secretary was after all its life and soul. He (Mr. Herbst) would, however, like to make one suggestion. The race of Chrysanthemums had been improved in one direction, but in another there had been no improvement at all. He referred to the plants in cottage and villa gardens. One saw there the same miserable little plants grown years ago. The Society had catered for the rich, let it now do something to improve the Chrysanthemums in poor men's gardens.

Mr. Holmes, on rising to respond, was very warmly received. This was, he said, the eleventh year in which he had responded to the toast of his health as Hon. Secretary. During that period great changes had taken place, and he had watched the progress of the Society year by year with pride, satisfaction, and pleasure. When the books were first handed to him it numbered fifty-five members, and had an income of less than £75 a year. Now, he was proud to say, the members numbered 633, and the income during 1888 would amount to nearly £1000. (Cheers.) Each year new features in the work of the Society had been introduced and new successes achieved, and the present year had been one of the most eventful of all. The great Show at the Aquarium could, in spite of prophecies to the contrary, of the trying season, of the terrible frost early in October which decimated many collections, and of the Chrysanthemum societies which held shows in all parts, be claimed as a grand exhibition, second to none ever held at the Aquarium or anywhere in the kingdom. Then there was the Catalogue, which had already been referred to, and the attempt to hold a provincial show. In reference to the latter, he must be careful of the terms he used, for opinions appeared to vary as to its success. For his part he repeated his opinion that it was a great success save in the want of competition in the open classes. He believed that in this Exhibition they had started a phase of work which must be persevered in year by year. The Conference, moreover, that was held at the same time was, it was the unanimous opinion, a success, and was, he thought, the most practical assembly of Chrysanthemum growers ever held. He hoped that the Exhibition would resolve itself into as important an affair as the November show, and concluded, amidst hearty cheers, by saying that he had no doubt of the future.

Mr. George Gordon, in responding for the Committees, attributed the success of their operations to the great interest which every member took in the work in progress. The Floral Committee had received great credit, but much also was due to the General Committee, by which the former was appointed. They did not, he said, take into consideration if one member could grow a Pumpkin half an ounce heavier than another, nor study his geographical position, but simply considered his suitability for performing the duties that would be assigned to him. He (Mr. Gordon) came into contact with large numbers of Chrysanthemum growers, but he had never heard the judgment of the Committee in the award of certificates called into question. The Catalogue, he thought, would prove of immense benefit to the Chrysanthemum world. Mr. Payne had already sent copies to America, Australia, Belgium, France, and Turkey, and would shortly be despatching a package to Japan. He would like to impress on other societies the great advisability of taking this Catalogue as the basis of their classification of varieties. He believed it would be of great advantage to exhibitors if such were the case. Numbers of varieties were easily separable into their respective classes, but with others it was difficult to decide whether they belonged to the

reflexed or the Japanese. An exhibitor might be disqualified at one exhibition where the National Society's Catalogue was not recognised for including a certain variety in his Japanese blooms, and again at the next for placing it among the reflexed. (Cheers).

The toast of the "Affiliated and Kindred Societies" was proposed by Mr. Blake and responded to by Mr. R. Dean, the latter remarking that he took every opportunity of pointing out the advantages of affiliation with the National Chrysanthemum Society. When he was asked what advantages would be derived from such a proceeding, he replied that they would come in contact with one of the best Presidents in the country. If he was asked who that was he replied, the "Grand Old Mum," and they joined at once. (Loud laughter). With the toast of the "Stewards," proposed by Mr. Payne and responded to by Mr. Long, and that of the "Press," proposed by Mr. Addison and responded to by Mr. W. P. Wright, in the absence of his senior, a most pleasant and enjoyable meeting terminated.

CHRYSANTHEMUM CULTURE AND VARIETIES.

[Read by Mr. Charles E. Pearson of Chilwell, at the Horticultural Club, on December 11th.]

I DO not propose to open my paper in the usual way, with a disquisition on the history of the Chrysanthemum, the exact date of its introduction, its use in and influence on Japanese art, and similar matters, partly because I think these things of very secondary interest to a horticultural association, and partly because I must confess to a blissful ignorance concerning them. I will therefore pass at once to cultural details, but before doing so must ask your kind indulgence if a great part of what I have to say appears stale news to you, the subject having been thrashed out so thoroughly that it is very difficult to extract anything fresh from it, though there is still need to keep reiterating the first principles of culture, as no easily grown plant is, leaving out special districts, more often seen in a miserable half-neglected state than the Chrysanthemum. Because the plant will exist with very little care it is often left until everything else in the garden has received attention, and is then attempted to be rushed with stimulants just at the end of the season. The fact is that to obtain any measure of success in Chrysanthemum growing, the plants should never stand still from the time the cutting is struck until the flower is in perfection; the successive pottings should not be delayed a day after the plants are ready, nor should they ever suffer by want of water through the season.

Leaving the question of seed-raising, the first step in cultivation is of course taking the cuttings. This may be done from November to April and even May, but I think the best time is the beginning of December—that is, if one has all the conveniences for growing the plants properly after being struck. Many amateurs and people whose accommodation is limited strike the cuttings, and then allow them to become drawn and spoilt for want of room to pot them at the proper time. Those in this case would do better to preserve the stumps of their Chrysanthemums in a cold frame until the spring, and then insert the cuttings when there is more chance of their receiving proper attention. In choosing cuttings preference should be given to the stout suckers which push from the roots when these can be obtained; but it is, however, not always possible to get these, especially from the Japanese kinds, many of which rarely throw up a sucker and only produce stem cuttings sparingly. Care should be taken in cutting these last down not to cut too low, but to leave a foot or so of the old stem, for want of which precaution we lost all our stock of Marguerite Marrouch some two or three years ago, not one of the stumps producing a cutting. Thousands of cuttings are spoilt annually by too much heat, becoming thin, spindly, and often mildewed, after which no amount of care can coax them into first-class plants. Putting them into perfectly cold frames is, I think, going to the other extreme, at least in our cold district, though much preferable to too much heat.

After several experiments I have settled upon one of our small houses as the best place for the purpose. It is about 30 feet by 10, has a path down the centre with a bed on each side, in which the cuttings are plunged. One 4-inch pipe runs down each side of the house and returns under the beds, and as these pipes cannot be made really hot the heat is just sufficient to keep the frost out. Though Chrysanthemums will strike in a cold frame, I am convinced that much time is lost during severe frosts, when for a month at a time they just exist under coverings of mats, &c., which of course exclude light as well as frost.

In taking cuttings begin if possible with the late flowering kinds, as Cherub, Mrs. Heale, Meg Merrilies, Princess Teek, &c., which require a long season of growth; insert them, that is all the incurved and Japanese, singly in small thumb pots. The Pompons and singles may be put seven or eight round a 4-inch pot. The reason for this is that some cuttings will strike much before the others put in at the same time, and so become drawn before being taken from the bed. The

singles and Pompons may be kept in order by pinching the points out as soon as they begin to grow, which cannot be done with the others if they are intended for specimen blooms. No glass or other covering need be placed over the bed except for the latest cuttings in spring, which may require a newspaper laid over the beds for shade in the brightest part of the day. As soon as the cuttings are rooted they should be at once removed to a bench nearer the glass to prevent drawing, one covered with ashes or cocoa fibre being preferable to bare wood, as it is easier to keep them in an equable state as regards moisture.

At this stage the grower should make up his mind if not done before what style of plants he intends to grow, whether the object is exhibition, cut blooms, or conservatory decoration.

Some people are utterly blind to the beauty of a flower which will not at least figure creditably on the front row of a showboard, while others never attempt to develop a bloom to the extent of which it is capable. I think myself that perfection as in most things lies between the extremes, and is best attained by endeavouring to bring each variety to perfection on its own lines—i.e., in the way best suited to its natural character. There are many varieties, as for instance Bouquet Fait, W. Robinson, Source d'Or, L'Or du Rhin, Chevalier Damage, Tendresse, &c., which naturally form dense, bushy plants smothered with bloom, forming beautiful objects for the conservatory and providing abundance of flowers for cutting. The only effect of disbudding these is to destroy the natural grace of the plant and throw away nine-tenths of the flowers, as the blooms are very little larger on a disbudded plant than when grown naturally. These remarks of course apply still more forcibly to the Pompons and singles. On the other hand, those who never disbud make almost as great a mistake, as it is only by limiting the bloom that the proper form of the incurved and the splendid size and colour of the Japanese varieties can be properly brought out. The waste is also not so great as it appears at first sight, as I have often noticed that perfect flowers, I suppose from their greater substance of petal, last much longer than ordinary ones.

The varieties which specially require disbudding are the large incurved kinds, as the Queen, Beverley, and Rundle families, and the largest Japanese, a list which may be got from the first prize lot at any good show. There is a further class, which is utterly useless unless well grown and disbudded to the crown bud, and which should be avoided by the ordinary gardener who does not make Chrysanthemums a speciality and study the peculiarities of each variety; of these are Comte de Germiny, Boule d'Or, Grandiflorum, Thunberg, Baronne de Prailly, &c.

An advantage of the mixed system of growing is the possibility of making more artistic groups when the plants are of varying size and habit, which give more light and shade in grouping and avoid the appearance of a gaudy carpet, which is attained when all the flowers are brought into one plane. It follows that to do this each variety must be studied separately and notes made of its habit, size of bloom, &c. It is not a bad plan with a new variety, if the plant be received early enough, to take off the top, strike it and run up without stopping for one or two good blooms, growing the decapitated plant into a bush, thus getting a good idea of its capabilities the first season. Going back to our cuttings, which were just struck, after being taken from the bed and placed in a lighter position for a few days, they should be transferred into small pots, about 2 inches will do, the soil used being decayed turf lightened with sand and leaf soil; this should not be made too firm the first potting, as the young plants recover and begin to grow again much more quickly if rather lightly potted.

Between now and the end of May is a very critical time with Chrysanthemums, during which numbers are wholly or partially ruined, many people having their frames filled with bedding plants, &c. During spring the Chrysanthemums have to put up with a position in the greenhouse, yards from the glass, and probably 10° or 15° too hot. They may remain in the greenhouse if cool and airy until the second move into 5-inch pots, after which they should certainly go into the cold frame, where, as soon as they have recovered from the potting, all the air possible should be given by tilting the lights, and, if possible, removing them altogether on warm days. The object is to secure a slow, sturdy growth as a good foundation for the future specimen. If grown too quickly the plants are ready for the final potting before the cultivator is, as this cannot be done until it is safe to place them outside, at least by anyone with ordinary accommodation.

This brings us to the most important operation of the series, the final potting. The principal points in this are the size of pot used and the character of the soil. The first depends upon the class of plant required. I use three sizes—7 inches for the plants to be run up with single stems,

except the Queen family, which require more room, and have 9 inches ; 10 inches for those to be stopped and grown as bushes ; and for forming large masses for cutting, 13 inches are employed, putting three plants in each. Our soil is turf from a rather light loam (alluvial drift), so that little or no sand is required ; it is, however, enriched by the addition of manures. We mixed up this year about sixteen cartloads ; this contained three good loads of dung, scattered between the layers of turf when it was stacked, about three months before wanted, to which was added half a load of wood ashes, 5 ewt. of bone dust, and 6 bushels of soot, the whole being turned two or three times to incorporate it thoroughly. In potting the last time the compost is made thoroughly firm, using a wooden rammer for the purpose.

The next item to be referred to is stopping. In the first place those plants which are required to produce exhibition blooms should not be stopped, but grown steadily on to their natural height, varying according to the variety from 4 to 6 and even 8 or 9 feet ; those for cut bloom and decorative work may be stopped when 5 inches high, again after making three or four leaves, and at intervals until the end of May, avoiding performing the operation within a few days before or after potting. If the aim is to get flowers of as nearly full size as possible on dwarf plants, the "cut down" system, as it is called, may be followed ; this consists in letting the young plant grow uninterruptedly until it is established in its 5-inch pot, then cutting it off to within 4 to 6 inches of the soil, after which keep somewhat dry until the stem has broken ; allow from four to eight growths according to the kind to grow without further interference, disbudding each to the crown bud. The time for cutting down varies with the character of the plant operated on. Free growing early varieties as the Rundles may be cut as late as the first week in June, but very late sorts as Princess Teek, Meg Merrilies, &c., should not be left later than May 1st, the Queen family about the second week of May, other kinds between these dates. Some varieties do better under this treatment than others, and are almost as good as if grown to full height ; examples—E. Molyneux, the Queen and Beverly families (especially the latter), Meg Merrilies, Mr. Garner, &c., while others have proved comparative failures under it ; of these may be mentioned Lord Wolseley, Prince Alfred, Jeanne d'Arc, Grandiflorum, Duchess of Albany, Marsa, and all the Anemones.

Now as to disbudding, which always appears somewhat of a mystery to the uninitiated, though very simple when once grasped. A Chrysanthemum when grown naturally produces three kinds of buds—viz., the July, the crown, and the terminal. The July, called so from the general date of its appearance, need scarcely be considered practically, as the shoot grows past it, and it remains a bud, withering up in time ; if the shoot be stopped at this bud when it appears, it will swell and grow into a flower, but nearly always a very coarse and deformed one. The crown bud is the one formed at the end of each of the three branches into which an unstopped plant naturally divides, and appears from the beginning of August (except in abnormally early plants) and onwards. Soon after the formation of this bud at the end of the branch three small shoots may be seen starting from just underneath it, and if the crown bud is intended to be retained for a show flower these must be removed early, or they will rob it and seriously retard its development. The removal of these three shoots to throw all the strength into the crown bud is what is technically called "taking" the bud. Most growers do this with a knife or pointed stick as soon as they can be seen, often injuring the stem, which is very soft at this time, and causing the bloom to come lop-sided. I think a much better way is to wait until the shoots are just long enough to get hold of and break them off with the thumb and finger. N.B.—The shoots are brittle and break easily in the early morning before the dew dries, when the sun is hot they are tougher. If these three shoots above referred to are allowed to grow, each forms a bud at its summit called the "terminal," generally surrounded by a cluster of smaller ones.

The great point in disbudding for exhibition is the proper time to take the buds ; this varies from the beginning of August for the very late kinds to the end of the month for the earlier. As a rule the Japanese may be taken before the incurved, which come coarse and out of character if taken too early, about the 20th being soon enough for them. When the crown bud appears too early, it and two of the shoots springing from its base should be removed, leaving the third shoot to produce a flower from the terminal ; this, in the case of some incurved varieties will, if not quite so large, be much more refined than from the crown. By careful disbudding, plants which would naturally flower from early November to Christmas may be bloomed all at one time.

FEEDING.—Almost every grower has his nostrum which he swears by (or makes a deadly secret, according to his character), but my own

practice is based on the idea that no one mixture contains every necessary ingredient, and that variety of food is most conducive to success. I begin with a little weak liquid, containing soot and cow-dung, as soon as the pots are full of roots after the last move ; this, however, very diluted until the buds begin to form, after which time watering is done somewhat as follows :—first time, clear water ; second, diluted stable drainage ; third, clear ; fourth, chemical manure (Beeson's, guano, Pearson's, &c., in turn) ; fifth, clear ; sixth, the stable drainage again very weak (the tank in which first dose was mixed filled up with clear water) ; seventh, clear.

Other points to be noted with regard to feeding are—always use manure water clear, and do not stir up the tank before drawing from it ; never give a dry plant liquid manure ; too much ammonia (the sheet anchor of many growers) spoils the foliage, making it brittle ; some plants are much more tender at the roots than others, and if watched will give warning when you are "coming it too strong ;" and, lastly, in a sunless season like the past it is easy to over-feed and produce coarse wood which cannot be ripened.

More definite information is still much needed as to the effect of different mixtures on the Chrysanthemum. It might be obtained with comparative ease if half a dozen good growers would each give their recipes, to be placed by the experimenter in as many tubs, each having a row of plants attached to it, to be watered from it. A few experiments of this kind would elicit much useful knowledge.

I should also be very pleased if any of our members could explain the erratic behaviour of some Chrysanthemums as regards time of flowering and colouration ; as examples, I may say that last year Martha Harding flowered after our show was quite over ; this year, grown in two or three different ways, it was in each way among the very earliest. L'He des Plaisirs two or three years since was nearly vermilion, and so gorgeous as to puzzle numbers of people as to its identity, since when it has been only noticeable from its dinginess ; Tokio also varies almost to the same extent.

INSECTS AND DISEASES.—The Chrysanthemum is less affected by these than many other of our cultivated plants. The following are, nevertheless, troublesome at times :—Green and black fly, earwigs, and mildew. The larva of the lady-cow will often keep the first two in order through the summer if not disturbed, and the larva of the lace-wing fly or golden-eye is also a splendid aphid destroyer, but is, unfortunately, rather plain and grubby in appearance, and is, therefore, by most gardeners looked upon as a "groob," and squashed accordingly. If the aphid, in spite of these enemies, increase too fast, they should be dusted with tobacco powder on a dewy morning, the best preparation I have tried being that called "Thanatos," sold by Messrs. Wood & Son. This should not be done after the plants are housed, as it gives them a filthy appearance when the rain cannot wash it off ; a better plan being to give a good fumigating the first quiet night after the plants are inside, whether they appear to want it or not ; they will then keep clean until after the show is over. For earwigs the only plan is trapping, and the best traps pieces of dry beanstalks ; these should be looked over every morning and the earwigs blown out into a pan of water. If mildew appears while the plants are outside syringe them with the following—1 lb. softsoap, $\frac{1}{2}$ lb. sulphur, and 10 gallons of soft water ; mix with boiling water, and add the remaining quantity cold, stir constantly while using. This is a perfect cure, and far before any method of dusting sulphur, &c. After the Chrysanthemums are housed, a coat of sulphur and linseed oil on the hot-water pipes is a very good preventive. I have not seen a speck of mildew in all our large show house this season, which I attribute to this precaution.

One useful way of growing the Chrysanthemum has been omitted—viz., as a table or decorative plant, for which, of course, as ordinarily seen it is entirely unfitted. To this end a few old stumps should be saved after the cuttings have been taken, and planted out in a bed as soon as sharp frosts are past, where they will require little attention. The first week in August cut off the tops 3 or 4 inches long, insert as cuttings, six in a pot, in frame behind a north wall, keep close and moist until rooted, then plunge in bed, allowing plenty of room to prevent drawing until time to house. The bloom being almost formed in the shoots before the cuttings are taken, they will not grow more than a few inches before flowering. Any good habited free blooming varieties will do for this purpose.

I am afraid, though I have left many details untouched, my paper has long surpassed the usual limits, so I will conclude with a few remarks on the novelties which have appeared this season. To begin with the summer bloomers.

Mrs. Burrell, sport from G. Wermig, has proved an acquisition, being a

beautiful delicate creamy yellow in colour, habit identical with Madame Desgrange. Another sport, deeper yellow, has also appeared; the colour, however, is not greatly wanted. Piercy's Seedling, orange yellow, very free and good habit, will do without staking. Alice Butcher, bronze sport from Lyon, very free, the best of its colour. Grace Attiek, white Japanese, opening in July. M. Van Hulle, bronze, fimbriated petal, very free.

Mr. Piercy of Forest Hill, though only possessing a garden of very modest proportions, has been doing good work in seedling raising. He finds that if old plants are put out early enough to bloom in July, with a few semi-doubles, as Hartland's Marguerite among them to supply pollen, the bees and flies will cross enough flowers to secure plenty of fertile seed. I saw three extremely promising varieties, at present only under numbers, which will be sent out next year if stock permits.

Of new incurved I have seen nothing worthy remark except the fine bronze sport from Mr. Bunn, H. Shoesmith, which will be a useful addition. The purple sport from Princess of Wales will be acceptable to the exhibitors, but is rather dingy in colour.

There are two or three fine additions to the Anemone class—Madame Robert Owen, grand white; Sabine, pretty primrose yellow; and Nelson, purple, the last being least desirable, being rather coarse.

After the rush of new Japanese the last few years bringing some fine novelties, if much that was inferior, it is disappointing to have very little beside rubbish to chronicle this year. It appears that the Frenchmen having made a market are proceeding, as they did with Roses, to deluge it with utter trash. Of ten of Délaux novelties, which I purchased as the cream of the set, nine are now on the rubbish heap, the exception being Madame Louise Leroy. Of new kinds which have been exhibited the following appear valuable:—

M. Bergman (Délaux).—Style of Mr. Garnar, but richer and deeper in colour.

Magicienne.—Fawn, shaded bronze and yellow.

Etoile de Lyon.—Blush white, shade rosy pink, but rather coarse. An immense flower, but rather coarse.

Viell Or.—Old Gold, grand flower, after Golden Dragon, but narrower in petal and much fuller flower. Then the finest novelty of the year, Sunflower, bright golden yellow, grand flower, with very long outer petals, which droop gracefully all round in the same manner as in Belle Paule.

In addition to these a number of very promising seedlings, which it would, perhaps, be unwise to particularise until seen in better order, have been imported via America. These, though suffering from the effect of the early frost which did so much mischief, appeared to me so promising as to give hopes that we may shortly be independent of the continental raisers, and enabled to give them what they so much need—viz., a year or two's complete leisure from selling to enable them to prove their seedlings instead of delegating that work to us.

WINTER CUCUMBERS.

THOSE whose task it is to keep up a continuous supply of Cucumbers through the winter months are well aware of the careful treatment the plants require to keep them in a healthy bearing state, and any hints that can be obtained are sure to claim attention and criticism. The cultural notes by Mr. W. H. Ward on page 513, useful as they no doubt are to many, are open to some comment.

In the first instance does Mr. Ward seriously believe that front and top ventilation in December absolutely necessary to insure success? If such is the case I should imagine the climate in his immediate neighbourhood is of exceptional mildness. I think I can lay claim to having been and still being fairly successful in their cultivation, and we never find it necessary to open the ventilators either top or bottom after the first week in November. Our only weakness for a fixed temperature is shown in the endeavour to maintain the temperature as near 60° as possible both day and night through November and from December onwards, raising it 5° or 10° according to circumstances. Should we be favoured with a glimpse of sunshine through these generally dull months growth is stimulated by the rise of temperature, and also consolidated by the additional light. What I consider so prejudicial to healthy fruitful growth is the practice of forcing hard through the dull dark days. Weak attenuated growth is the result of that, and generally the total collapse of the plants before the end of the year. From experience I have come to the conclusion that what I term the "sun bath" is an important item in obtaining fruitful growth, which nothing but the rays of the sun can produce. The practice of giving air is, I consider, open to several objections. We

let the previous sun-heated air escape that gives life and energy to the plant and admit in its place a body of cold air. For what purpose? merely to keep the temperature at the precise point prescribed by horticultural faddists. We also promote evaporation and favour the escape of moisture, and consequently induce the attack of red spider, mildew, and other pests.

Why do we ventilate? is a question I have sometimes asked brother craftsmen, and if the answer is more amusing than instructive it is, I suspect, because this simple operation is practised more by rote than by circumstantial requirements. I hold the minimum temperature should be the only fixed one, and this should be ruled by the number of degrees rise that the sun will produce at that particular time of year. For instance, through November, when the maximum temperature desired is 80° or thereabouts, the power of the sun's rays, owing to the obliquity of the earth, can seldom raise the temperature of a plant house more than 20°, so that the minimum of 60° will be found about right. Towards the end of the month and through December the minimum can be raised to meet the still less heating power of the sun, and continue to do so until the turn of the year, even if the temperature should rise to 85° or even 90°, as it will sometimes do in bright frosty weather. When the fires have been kept going sharp to keep up the increased minimum there is no occasion for alarm, much less for opening the ventilators, as owing to the low point of the sun's meridian at this time of the year its influence is of short duration.

After the turn of the year, contrary to what would seem the proper theory—viz., to reduce the minimum according as the sun's power increased, we find that the plants will finish their career creditably towards the end of March under very strong heat, a plentiful supply of moisture, and absolutely no ventilation whatever, and this, with a freedom from mildew and red spider, that advocates of free ventilation appear to suffer from.

One word as to mildew. Mr. Ward appears to believe that its appearance is caused by the excess of atmospheric moisture. How he arrives at this conclusion would, I think be interesting to many who are troubled with this dire pest, though I believe this is a theory that is very popular. I am totally opposed to the idea of a hot moist atmosphere being favourable to its growth, and why this opinion has gained ground I am at a loss to say, unless that the mould engendered by damp organic matter is believed to be in some way connected by a fancied similarity of organism.—M. COOMBE.

ANOTHER ROSE BOOK.

Cultural Directions for the Rose, with Descriptions of the Newest and Best Roses in Cultivation adapted to various circumstances and situations, &c. By JOHN CRANSTON, King's Acre Nurseries, near Hereford. Seventh Edition, revised.

IF "in the multitude of counsellors there is wisdom" then ought Rose-growers to be amongst the wisest of the earth; books of all sorts are written for them, and instructions are weekly provided in the various horticultural publications, of which there is certainly no lack. Amongst those who have given to the world the result of their experience is the author of "Cultural Directions for the Rose," which was published thirty years ago, and has now reached its seventh edition. Those who have seen Mr. Cranston's flowers at Rose shows, and, above all, those who have ever visited his nurseries at Hereford, will be fain to acknowledge that no one is better qualified to tell us about the Rose than the popular author of this book, and in this edition he has certainly striven to make more secure his claim to be one of the best instructors we have on the subject of which he writes.

On the subject of stocks there is still a good deal of difference of opinion. The tendency is unquestionably towards the substitution of the Briar for the Manetti. Mr. Cranston is a strong advocate for the latter; he has strong reason to praise it, for it has stood him in good stead in times past; but on such a soil as his we should have supposed that plants on the Briar seedling or Briar cutting would have succeeded best; indeed, the last time that we visited his grounds we noticed large quantities of the seedling Briar were being worked, and it is somewhat remarkable that although other stocks have been from time to time praised up, still the two which Rose-growers mostly know are the Briar in some of its forms and the Manetti.

On the subject of pruning there are some excellent directions given. Although perhaps a little too much stress is laid upon the obtaining of symmetry in the plants, it is easy to give directions, and with the comparatively young plants of a nursery it is more practicable than in private gardens, where plants of four or five years of age will not conform themselves so readily to the operator. Like most Rose-growers

Mr. Cranston advocates pruning in the early spring months, but even on this point he will find people to differ. We met the other day an extensive Rose-grower who advocated the plan with all newly planted Roses of pruning them at the time of planting; this is wise in spring planting, but not in autumn.

There is no subject in connection with the cultivation of the Rose which Mr. Cranston has left untouched in the first part of his book. Names, labels, insects, in fact everything that could by possibility be considered needful for the grower to know has been provided for him by one who knows what he is writing about, and can bring the test of experience to verify his advice.

In the second part of his book Mr. Cranston has given most valuable aid to Rose-growers of all kinds by the selections which he has given of the best Roses, nor has he in this confined himself to such as are suited for exhibition. He has considered the wants of those who dwell in smoky towns and of those who live in cold localities. He has given lists to suit even the smallest growers, of the best six Roses of different colours, the most highly scented Roses, the most brilliant Roses for beds, and, in fact, selections for all kinds of uses to which the Rose can be put, a very copious calendar of operations, for which no one is better qualified. The book concludes with what will be of very great value to rosarians of all kinds, a complete catalogue of Roses. Hitherto this has been only accessible in the carefully compiled catalogue of Ketten frères of Luxembourg, or in the more elaborate "Dictionnaire des Roses," and this list, while not so fully descriptive as either of those mentioned, will, nevertheless, be sufficiently so for most English growers. Mr. Cranston does not profess that it is perfect, and, indeed, it is very difficult to make a list which shall be free of mistakes. This difficulty was experienced when the Committee of the National Rose Society compiled their catalogue of a selected number, and is still greater when all the Roses ever sent out are to be included; but there is one series of mistakes which we think Mr. Cranston might have avoided—not giving the names of Roses which have been pronounced so much alike that they are not to be scheduled together; thus there is nothing to show to us that Marguerite Brassac is only another name for Charles Lefebvre, or Alba Rosea for Madame Bravy, yet they have long since been so bracketed; but, notwithstanding, we must hail this list as a very great boon for Rose-growers. Mr. Cranston's description of Roses in his second part is very full, and those who wish to find out the character of any Rose has only to refer to this list to find his wants met.

We have, we hope, said enough to assure the Rose-grower, but especially the beginner, that he may find in Mr. Cranston a wise instructor and safe guide, and that although he may, perhaps, differ from him in some minor points, yet these are inseparable to Rose growing as to most other things. There is no general consensus of opinion in most things, and what is most wanted is the opinion of a sensible and practical man, and that, as we have said, they will find in Mr. Cranston.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 11TH.

SCIENTIFIC COMMITTEE.—Present—Mr. G. Wilson, in the chair; Hon. and Rev. J. T. Boscawen, Professor Church, Dr. Hogg, Dr. Scott, Mr. D. Morris, Mr. J. O'Brien, and Rev. G. Henslow, Hon. Sec.

Oak Wood, Defective.—Specimens of Oak wood, forwarded by Mr. Burbridge, which had been used for spokes of wheels, but found to be remarkably brittle and consequently useless, were submitted to Professor H. Marshall Ward for examination and report. The following communication was received from him:—"I have cut numerous sections of the pieces of Oak, and have made a very thorough examination of the wood, but must say I can find no traces of fungi or pronounced decomposition. Nevertheless, the tracheides of the wood seem to be abnormally short, and have occasionally granular 'deposits' in them—also in the medullary ray cells—which I should like to know more about. I cannot explain the matter, but should be glad of further specimens for examination."

Ivy, Staminody of the Pistil.—Mr. Henslow submitted some specimens of abnormal Ivy blossoms to a microscopical examination, which were exhibited at the last meeting by Dr. Masters, together with drawings by Mr. G. W. Smith. The dried condition of the flowers precluded a very exact determination of the abnormality; but there appeared to him to be little doubt but that stamens replaced the carpels. The sepals, petals, and stamens were normal, but above the superior disc—which is normally formed by the upper and exposed part of the carpels—were a crown of supernumerary anthers. The vascular cords which normally represent the dorsal ribs of the carpels bore the anthers. In the centre was a depression in lieu of the ovary cells, and apparently some minute and rudimentary anthers occupying their place. These seemed to be due to staminody of the placental cords, which normally occupy the centre of the inferior ovary.

Stachys tuberosa: Analysis of the Tubers.—Professor Church gave an account of an analysis of the tubers of this new vegetable which he had himself made, and by which he confirmed those of Dr. A. V. Planta, recorded in *Landwirtschaftliche Versuchstationen*, Nos. 5 and 6, 1888. It appears that they contain 78 per cent. of water, 1.5 per cent. of albuminoids, 1.7 per cent. of non-albuminoids or amides, 16.6 per cent. of sugars, 0.7 per cent. of fibre, 0.1 per cent. of ash, 0.2 per cent. of fat, and a trace only of starch. Comparing this analysis with that of Potatoes, it appears that the water is in larger quantity, it being 75 per cent. in them—the flesh-forming albuminoids are rather more than in Potatoes,

while the sugars replace the starch, of which there is some 15 per cent. in the average analysis of the Potato.

Satyrium sp. with "Supertuberation."—Mr. O'Brien exhibited palmate tubers of some South African species, with showed two years' growth, having been plunged in moss only; the tubers, instead of developing a leafy axis, had formed fresh tubers only, the stem and leaves being produced in miniature, being about half an inch in height. Mr. Wilson mentioned the fact that Lilies sometimes behave in the same way, and that the process was identical with "supertuberation" in Potatoes, in which case the "eyes" gave rise to fresh tubers instead of stems, when situated too deep and with too much heat, according to the experience of Mr. Boscawen. Mr. O'Brien remarked that the importance of the knowledge of the above phenomena lay in the fact that it was often supposed that tubers and bulbs were lost or decayed, from the non-appearance of the flowering stems, while they might still be present in the soil, but were for two or three years simply reproducing bulbs at the expense of the old one, without flowering at all.

Lime with Contorted Boughs.—Mr. G. Swailes forwarded a young live tree grown from a layer, the only one of 500 which exhibited the peculiar growth. A graft taken from it in the spring exhibits the same peculiarity. Dr. Hogg remarked that it appeared to resemble the "contorted" variety of the Hawthorn. The curving and twisting was apparent even in many of the minutest twigs. It was thought by some to be due to mischief or injury by insects; but the above facts seem to point to other causes. It was referred to Chiswick to be grown to prove the constancy of the feature or otherwise.

Christia.—This is a new production for antiseptic bandages, invented and patented by Mr. T. Christy, of 25, Lime Street. It is constructed of thin whitey-brown paper, expressly made of Manila Hemp (*Musa textilis*), which consists purely of remarkably long liber-fibres, which doubtless tend to give it greater tenacity. It is then subjected to a process with glycerine, olive oil, and other substances, which render it translucent, with the appearance of oiled silk. It subsequently is treated with salicylic acid, carbolic acid, or other disinfectant, and rendered antiseptic. Its advantages are—great tenacity, extreme lightness, being not more than one-third of the weight of oiled silk or gutta-percha sheeting, antiseptic and perfectly impervious to moisture. It was thought that it would prove so exceedingly useful in horticulture—e.g., for binding up in budding, sending specimens by post when the exclusion of air is essential, while strips would be serviceable for tying plants to stakes, &c.

Korsambi Nuts.—Mr. Henslow showed specimens, received from Mr. Christy, of the seeds of *Schleichera trijuga*, of the order Sapindaceae. It was supposed to be the source of Macassar oil, but this was strongly doubted. Mr. Morris observed that it is called the "India Oak tree," and is abundant in India and Ceylon, and is valuable for its timber.

Juniperus occidentalis (Hook).—A specimen, collected in Eastern Oregon, U.S.A., by Mr. William Stewart, was forwarded by him from Greenock, N.B. It was first found by Douglass in the Story Islands in the Columbia River. It was also found in the Klamet Mountains, in the Oregon territory, at 5000 feet. It grows from 40 to 80 feet high, and, like other species, varies in foliage in passing from the young to the older stages. The specimen sent was spring-leaved, or in the characteristic condition of the young stage. It is remarkable for the strong and disagreeable odour when bruised—"Gordon's Pinetum," page 163).

Centenary of the Dahlia.—Mr. Henslow called attention to the fact that the year 1889, besides being the centenary of the Chrysanthemum in Europe, was that of the Dahlia in England. It was introduced by the Marchioness of Bute in 1789, and figured with single and double forms in "Bot. Mag.," vol. xlv., t. 1835, and "Bot. Reg.," vol. i., t. 53.

RANUNCULUS CULTURE.

UNQUESTIONABLY one of the most beautiful flowers of spring yet absent from many, if not the majority, of gardens. Formerly collections of named varieties were grown with much care by a few old florists, but these fanciers are now more scarce than growers of florists' Tulips are; indeed the Ranunculus is scarcely grown as a florists' flower, but for decorative purposes, and for market, the cultivation of varieties in mixture is extending. The old florists used to be very particular in choosing suitable positions for their Ranunculus beds, also in the preparation of the soil and planting. Here are the instructions of one of them:—

"SITUATION.—It is only a waste of time and money to attempt to grow the plan's within the influence of a smoky atmosphere near large towns, or upon a high hill in a dry soil, or in a swamp. The florist must choose a place for the Ranunculus bed neither too high nor too low; let it be a level surface, and if it be sheltered from the northern blasts so much the better.

"SOIL.—The soil should be retentive of moisture. The best kind is the virgin mould of some alluvial soil on the banks of a river, or some lowland pasture. It should be of a rather close texture, without any small stones or sand amongst it. Lay it up for a year, turn it over until it is well incorporated, wheel out the old soil to the depth of a foot or more, place a thin layer of very rotten cowdung at the bottom, and upon that the fresh soil. If the situation is low, with a wet subsoil, it must be well drained; but if the subsoil is dry there is no necessity for drainage. If

the soil should be thought too poor, a small addition of decayed cowdung will be advisable; but it must be so decomposed as to appear like a black powder. Let it be thoroughly mixed with the

become tolerably dry. Some time about the end of February or the first week in March, rake the surface of the bed in the morning of the day previous to that fixed upon for planting. Some recommend

FIG. 63.—RANUNCULUSES.

soil whilst making the bed, in dry weather, about the month of September.

"PLANTING.—The season for planting is in the early spring, as soon as the most severe frosts have passed and the ground has

steeping the roots for twelve hours in water before planting, but we think this not necessary, except the planting season has been from some cause or other put off till the middle of April; then it may be useful. Supposing, then, that the weather is propitious,

and all things prepared, commence by drawing with a hoe a drill across the end of the bed, $1\frac{1}{2}$ inch deep; if deeper the roots will be weakened the succeeding year, by forming a kind of stem nearer the surface; and if shallower, the plants are more liable to be struck with drought. Plant the tubers, if large, 4 inches apart in the row; if small, $3\frac{1}{2}$ inches will be a sufficient distance, and cover them with fine sand. This will cause the tubers, when they are taken up in July, to come out of the ground quite clean for keeping."

Very precise instructions were also followed in other details of culture; but it is not as a florist's flower that the *Ranunculus* is alluded to now, but as an ordinary garden flower that may be grown to give satisfaction by simpler methods of culture than those above described, though the instructions are good. We have found it is not a waste of time and money attempting to grow *Ranunculuses* near towns, as we have seen brilliant masses of them within two miles of Charing Cross; and, as to soil, they will grow in such as will grow good Cauliflowers. In respect to the time of planting, some of the most extensive growers of these flowers for market have probably about finished planting their tubers now. They plant in November, onwards, as the ground may be in suitable condition, not deferring the work till spring; but when severe weather follows, and the tubers have started, being in what is known as the "milky" state, the surface of the ground is covered with litter, as in the condition indicated they are liable to injury by frost; but when the growth pushes through the ground they are regarded as safe, being quite hardy. When grown on a limited scale in gardens cocoa-nut fibre refuse would answer for protection if litter were considered unsightly. The advantages of late autumn planting consists in the roots taking good and deep hold of the soil, hence the plants better endure dry weather in late spring, which often causes them to wither prematurely when grown from tubers inserted in March. The flowers figured represent ordinary decorative forms, and were grown in a London garden from mixed tubers, which are the reverse of costly. A small leaf-mining insect often injures the plants, the larvæ of a small fly similar to that attacking Celery. Sprinkling with a solution of softsoap with half a wineglassful of petroleum well mixed in each gallon, applying in the evening, not in the morning, is a safe and good deterrent of the attacks.

ROYAL HORTICULTURAL SOCIETY.—We understand that with a view to retrenchment of office expenditure, and with the hope of being able to devote more money to Chiswick, the Council of the Royal Horticultural Society have decided to leave the position of Assistant Secretary vacant for the present. Mr. Chas. J. Grahame, who has so well filled that office during the past year, fully concurs in the propriety of this step, and having the Society's welfare at heart is in entire accord with the Council's decision. The Hon. Sec., the Rev. W. Wilks, has most kindly undertaken to be responsible for all official correspondence, and considering the main objects he has in view—viz., the habilitation of Chiswick and the resuscitation of the Society's Journal, we are sure that he will meet with every indulgence at the hands of Fellows and others, if sometimes he find it impossible to keep the correspondence quite up to date.

— THE usual monthly dinner and conversazione of the HORTICULTURAL CLUB took place at the Club Rooms, Hotel Windsor, Victoria Street, Westminster. The chair was taken by the Hon. and Rev. J. T. Boseawen, in the absence of Mr. John Lee from illness—an illness from which he is happily making a rapid recovery. There were present—Dr. Hogg, Messrs. Pearson, Lindsell, Denny, Turner, Pearson, &c. The subject for discussion was the Chrysanthemum, being opened by Mr. Charles E. Pearson in an excellent practical paper, which touched upon the various points of culture. An interesting discussion took place, in which the Chairman, Dr. Hogg, and others joined. A vote of thanks was accorded to Mr. Pearson. The paper referred to appears in the present issue of this Journal.

— THE HORTICULTURAL DIRECTORY AND YEAR BOOK FOR 1889 (published at this office) is now issued in an enlarged and greatly improved form. It comprises some 368 pages, and includes full list of gardens, garden owners, and gardeners in England, Scotland, Ireland,

and Wales, nurserymen, and horticultural builders, a much extended list of horticultural societies, and the principal continental and American nurserymen. A useful feature is added in the twelve pages devoted to descriptions of plants certificated by the Royal Horticultural Society from November, 1887, to the corresponding month this year. A series of tables of special service to horticulturists is another addition, and with ordinary [calendrical] information renders the book a substantial shilling's worth.

— THE following are the principal arrangements of the ROYAL BOTANIC SOCIETY FOR 1889, but as that year will be the fiftieth anniversary of the Society, a special fête is under consideration and will be duly announced:—Spring Exhibitions, Wednesdays, March 20th, April 10th; gates open at 2 o'clock. Summer Exhibitions, Wednesdays, May 15th, June 19th; gates open at 2 o'clock. Evening Fête (probable date), Wednesday, July 3rd; 8 to 12 P.M. Promenades, Wednesdays in May, June, July, commencing May 8th; exhibition and fête days excepted. Lectures, Fridays at 4 P.M., May 10th, 17th, 24th, 31st, June 7th, 14th. General Meetings, for election of new Fellows, scientific discussions, &c., Saturdays, at 3.45 P.M., January 12th and 26th, February 9th and 23rd, March 9th and 23rd, April 13th and 27th, May 11th and 25th, June 15th and 29th, July 13th and 27th, November 9th and 23rd, and December 7th. Anniversary, Saturday, August 10th, at 1 P.M.

— A CAUTION TO NURSERYMEN.—I feel it my duty to ask you to note, for the benefit of nurserymen and seedsmen, to caution them about executing orders from unknown individuals in the neighbourhood of Bristol. A nurseryman saved himself from executing a very large order by paying a personal visit to the place where the goods were to be sent. The address looks well upon paper, and therefore might entrap anyone. I need not say the large order will not be executed, so look out, those in the trade.—ALFRED OUTRAM.

— IN "A Kitchen Gardener's" paper on "PEAS IN 1888" in the *Journal of Horticulture*, page 536, he speaks of "Lynn's" Black-eyed Marrow Pea (Dicksons) as though it was a variety introduced by one of the firms of Dicksons. It is a very old variety, for I have known it quite thirty years, and is of the type of Knight's Marrow, also old varieties, and it is "Lyne's," not "Lynn's," but I do not know who he was. Dr. Hogg could no doubt tell us, or some of our older London wholesale seedsmen. Like many other old varieties, it has passed almost into oblivion, and I think it is probably grown more in America and the colonies than in England, as I was some years ago connected with a London seed house who used to report it, but we never had it in large quantities.—W. D. S.

[Lynn's (not Lyne's) Wrinkled Marrow Pea was raised forty years or more ago by Mr. Lynn, the fishmonger in Fleet Street, whose shop is still in existence. Having accidentally discovered a few wrinkled Peas with a black eye (hilum) among a sowing of Knight's Dwarf Marrow, he selected them and grew them apart. He brought them to the notice of Messrs. W. & J. Noble, who were at that time seedsmen at 152, Fleet Street, and by them the Black-eyed Marrow was brought into notice. It is a very hardy variety, and used to be grown in the north; but not being of desirable quality it nearly dropped out of cultivation.]

— WE are informed that the Committee of the HULL AND EAST RIDING CHRYSANTHEMUM SOCIETY have decided to hold the Show in 1889 on Thursday and Friday, Nov. 14th and 15th.

— GARDENING APPOINTMENT.—We understand that Mr. G. Merritt, gardener to Lord Daere, Kimpton Hoo, Welwyn, Herts, will shortly go into business at Harpenden as a florist and market grower, and he will be succeeded by Mr. Charles Martin, foreman at Holker Gardens, Lancashire.

— CONSIDERABLE quantities of AMERICAN APPLES are now reaching the British markets, and it is said that the Apple crop in Canada and the United States is the largest ever known; 536,000 barrels have already been shipped to Europe, against about 290,000 during the corresponding months of last year.

— THE "GARDEN ORACLE" for 1889 prepared by Mr. Shirley Hibberd, and published by Messrs. W. H. & L. Collingridge, is before us, and will be handy for reference during the year by persons engaged in gardening. It contains a concise and excellent monthly calendar of operations, also a good calendar on bees, lists of new plants, fruits, and vegetables, with selections for cultivation, a full chapter on the cultivation of Chrysanthemums, and an extensive catalogue of large flowering varieties.

— MR. FRANC GIBB DOUGALL, 167, Canning Street, Glasgow, writes respecting the GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY:—"I beg to inform you that the flower shows of this Society for 1889 will be held, spring, Wednesday, 27th March, 1889; autumn, Wednesday, 4th September, 1889. Both to be held in the City Hall, Candleriggs, Glasgow."

— A GARDEXERS' SOCIETY FOR EALING.—A Society of this character has recently been started at Ealing with every promise of being most successful. The President is E. M. Wilson, Esq., J.P., and the Hon. Secretary is Mr. E. Chadwick, of Hough Hill House Gardens, Ealing. Already three addresses have been delivered, the opening one by Mr. Richard Dean; one on Ferns, by Mr. A. Wright, The Gardens, Devonhurst, Chiswick, illustrated by microscopes; and a third by Mr. S. Coulter, on Pruning Fruit Trees. The meetings take place on Thursday evenings, in the Girls' School Room, Ealing Green.

— IN a provincial paper professing to deal with horticultural subjects an extraordinary description is given of the NATIONAL CHRYSANTHEMUM SOCIETY'S EXHIBITION at Sheffield recently, in which amongst other strange statements, it is remarked that in the open class for groups of Chrysanthemums arranged for effect there was only one entry, which gained "the first prize of £100." This will be good news for the exhibitor, but he will find it rather difficult to prove his claim. Mr. Parker's address is given as "Droitwich." The paper mentioned is also interesting in other departments, for in an article on the Cactus we find special reference to "Epiphillum Tumicatum," and "Speciosissimus Jenkensoni or the Rainbow Cactus."

— THE BIG TREES of AUSTRALIA.—"Is it possible," says a writer in the *Melbourne Leader*, "that the big trees on which we have been priding ourselves have no more foundation in fact than the Australian natives' legends of the bunyip? It has been for years an article of Australian faith that we licked all creation in the way of tall timber, but when a gentleman tries to put it to the test and offers a reward of £20 to anyone who will show him a tree of 400 feet in height, with £3 extra for every 5 feet over, no backwoodsman comes forward to earn the reward. A tree of 500 feet in height would be rather difficult to hide. We either have them in the colony or we have not. And the conclusion that everyone will draw if there is no claimant comes forward to demand such a very easily earned reward is that our Gums are not the McKays they were reported to be."

— AN article in the *Nineteenth Century* for December contains an article on the FRUIT-GROWING REVIVAL by a horticultural editor, and in the introductory remarks the following passage occurs. "In 1886 a panacea for the agricultural distress was announced in the shape of Tobacco growing. 'Raise Tobacco instead of corn,' was the burden of the advice tendered to the bewildered agriculturist struggling in the throes of a bad season; and poor Agricola, whom his detractors assert is so opposed to innovation, straightway set to work to test whether *Nicotiana affinis* would yield him a better return than corn." It will apparently be news to the writer in question and the editor of the high-class publication in which the above is allowed to appear, to learn that *Nicotiana affinis* does not afford the Tobacco of commerce, and has never been recommended for culture by agriculturists unless by some wild writer utterly ignorant of the subject with which he attempts to deal.

— "A FEW HINTS ON WATERING PLANTS" was the title of a most interesting, valuable, and practical essay read before the members of the Paxton Society at the Saw Hotel recently by Mr. L. Twigge, of the firm of Messrs. Twigge & Son, Bradford Road Nursery, St. John's. The President of the Society (Councillor Milnes) occupied the chair, and Mr. Herbert Chapman acted as Vice-Chairman. There was a moderate attendance of the members. Mr. Twigge dealt with the subject in a manner which at once convinced his hearers that he had devoted considerable attention to this important and absolutely necessary process in connection with gardening. He pointed out that many ladies and amateur gardeners frequently kill plants by kindness or over-watering, whilst on the other hand large numbers of plants are lost from neglect or carelessness in respect of want of watering. After an interesting discussion, a hearty vote of thanks was accorded to Mr. Twigge, on the motion of Mr. E. Fenner of Sandal, seconded by Mr. G. Gill of Eastmoor.

— AT a recent meeting of the Manchester Horticultural Society Mr. Gleeson of Clumber Gardens, read a paper on THE PINE APPLE, and in the course of a discussion which followed, Mr. Bruce Findlay is

reported to have made these observations—"They were all aware that Pines have been for the past twenty years imported into this country from the Island of St. Michael. In the year 1868, 471 of these Pines were imported into London, eight years later the number had increased to 35,000, and he would not be far wide of the mark in saying that the number had now reached 100,000 annually imported into this country. The cost of producing and delivering them in London is about 5s. each, and they could now get good Pine Apples at less than 7s. 6d., which a few years ago would have cost two or three guineas each." We should think that the number imported exceeds the total given above, as they are frequently sold in consignments of over 5000 in Covent Garden Market, and we have seen a large portion of the spacious Floral Hall filled with these fruits. Good Pines can also be purchased at a lower rate than that named.

— AT the last meeting of the NATIONAL CHRYSANTHEMUM SOCIETY'S FLORAL COMMITTEE for the present year, held in the Royal Aquarium, Westminster, recently, there were present E. J. Sanderson, Esq., in the chair, with Messrs. Ballantine, R. Dean, L. Castle, G. Gordon, H. Cannell, G. Addison, Kendall, C. Gibson, Swift, G. Stevens, R. Owen, and Mardlin. Several novelties were exhibited, and first class certificates were awarded for the following varieties. *Etoile de Lyon*, from Messrs. Cannell & Sons, Swanley, a Japanese variety with large blooms and broad straight florets of a rich crimson colour. It was also shown by Messrs. Laing & Sons, of rather lighter tint. Mrs. W. A. Harris from Mr. Beckett of Elstree, another fine Japanese variety, with full blooms white tinted pink; *Cæsar*, from Mr. Elliott of Jersey, a large or Japanese Anemone, ray florets dull red, centre yellow, but it was not in good condition though promising; *Primula sinensis* Cannell's Pink, of a very soft clear pink, the flowers well formed and the habit good. Mr. Beckett also showed fine blooms of *Pelican*, and Mr. Mursell of Streatham had extremely handsome examples of *Gloriosum*, and numerous other varieties were shown of differing merits.

— A DANGEROUS COMPOUND.—Mr. Iggulden writes:—"I have often recommended the use of Smith's weed killer for destroying weeds, and have induced others to give it a trial. In one instance unfortunately the introduction of this poisonous mixture has resulted in the death of a Frome child. It appears that about eighteen months ago what was left in a barrel was run out into bottles, and the receptacle returned to the vendor of the weed killer. During the following summer the bottles were supposed to be emptied, and they were then set in an outhouse. In the course of alterations recently commenced a workman brought his child on the place, and he shortly after was taken ill and died. Death was attributed to poison ("arsenate of soda in solution"), and it was ultimately discovered that the poor boy had drank out of one of the supposed empty bottles. According to the evidence of the county analyst, a teaspoonful of the fluid found in the bottles was said to be capable of killing a child that swallowed it. Gardeners who use the weed killer are distinctly informed that it is a poison, but it is doubtful if many of us were aware how really dangerous it is. The fact of its being so need not deter anyone from using it freely, for these weed killers are great economisers of labour, but it ought not to be left about in a careless manner, and certainly not stored in bottles. Neither the gardener nor the manufacturer was blamed for the unfortunate mishap, and I certainly do not impute any blame to anyone. It is what any of us might have done, and I am giving this warning in order to deter others from acting in a careless manner where poisons are concerned."

— THE monthly meeting of the NOTTS HORTICULTURAL AND BOTANICAL SOCIETY was held at the Arboretum, Nottingham, on Wednesday evening last, December 12th, for the purpose of hearing a number of essays read on "The Duty of the Employer to his Gardener," for which three money prizes had been offered by Mr. Richard Sankey of Bulwell Potteries, Nottingham. Mr. Sankey presided, and amongst a large attendance were Mr. Samuel Thacker, Minever House, Nottingham; Mr. C. J. Mee, Wollaton Hall Gardens; Mr. J. S. Belliss, Newstead Abbey Gardens; Mr. N. H. Pownall, Lenton Hall Gardens; Mr. R. Waters, Welbeck Gardens; Mr. J. H. Walker, Hardwick House Gardens; Mr. J. R. Meadows, Rock House Gardens; Mr. Geo. Wilson, Aspley Hall Gardens; and Mr. N. Gorman; Mr. Edward Steward, Secretary. Seven papers were read by Mr. Steward, who consented to undertake the task, and each of these was highly interesting and replete with information and suggestions of a practical character. The whole of the papers had been written with much care, and in most cases with conspicuous ability. The essays were read under their respective *noms de plume*, and the prizes were awarded by ballot, the

result being:—First prize, £1, with the first class certificate of the Society, Mr. J. H. Walker, gardener to John Wesley Lewis, Esq., Hardwick House, Nottingham. Second, 15s., with the second class certificate, Mr. Geo. Wilson, gardener to E. W. Field, Esq., Aspley Hall, Nottingham. Third, 10s., with third class certificate, Mr. G. Camp, Wollaton Hall, Nottingham. The Chairman, in presenting the prizes to the successful competitors, congratulated them upon the excellent manner in which they had dealt with such an important subject, and hoped the various opinions expressed in the essays would be productive of much good. Mr. S. Thacker offered a few encouraging remarks to the unsuccessful competitors, and on the motion of Mr. Walker, seconded by Mr. Wilson, a vote of thanks was passed to the donor of the prizes.

— THE annual dinner of the YORK FLORISTS' SOCIETY took place last Saturday night in the "Old George." The City Sheriff (Councillor Matthews) presided, and had with him at the cross-table the ex-Mayor (Alderman Rymer), the Rev. F. Umpleby, Sir Joseph Terry, the ex-Sheriff (Mr. S. Border), Mr. Cowper, Vice-President of the Society, &c. The Secretary (Mr. Lazenby) occupied the vice-chair. The usual patriotic toasts having been honoured, the Chairman proposed the toast of the evening, which was "Success to the Ancient Society of York Florists, and all Lovers of a Garden." He believed the Society was first established in 1720, and he need not tell them that it had had a somewhat chequered career. If it had not been for a few enthusiastic lovers of flowers it would not have been in existence. The establishment of the Chrysanthemum Show nine years ago had contributed greatly to its strength. Its minor shows, by the kindness of successive Lord Mayors held in the Guildhall, had been of such excellence that they had been thoroughly enjoyed and looked forward to with pleasure by the citizens generally. Mr. Key proposed "The Treasurer," and Mr. Fielding, the gentleman toasted, responded. He was happy to say that the Society was in a good financial position. At the termination of the last year they had a balance of £150; they had been able to maintain their numerical strength. He was not aware, indeed, that they had ever been so strong as they were that day. The annual income by donations, &c., had been £120. The money from the Chrysanthemum Show had not been so large as last season, but they had no great cause of complaint. The amount received was £140, and they would be able to pay their way, with possibly a £10 or £20 to add to their balance. Alderman Sir Joseph Terry next proposed "The Secretary," who understood from his daily avocations what ought to be done, and he was fully equal to the demands made upon him. Mr. Lazenby, in acknowledging the toast, said as they were aware he had from the time of his connection with the Society sought its extension and welfare. Since he joined it had very much increased in strength and usefulness, and was, in his opinion, second to none of its kind. He trusted it would keep on the fair way of prosperity, and that the members would co-operate to that end.

LONDON'S LESSER OPEN SPACES—THEIR TREES AND PLANTS.

(Concluded from page 402.)

A SOMEWHAT bustling, decidedly not rural, road, from Oxford Street northward, is the Tottenham Court Road. We can hardly picture it to ourselves as it was less than a century ago, when it led to the old manor of Tottenham Court. This name, however, has no connection with the village farther off, but seems to have been originally "Tuthill" or "Tottenhill." The mansion, by turns the property of the Graftons and Southamptons, was on the east side of the road, the fields lying behind it being called the Tottenham Fields. On the west side of the road were the Bedford Fields; both are now the site of streets and squares. In the seventeenth century the manor-house became a tavern and its private grounds a tea-garden. As a reminiscence, when the latter was cut up for building during the reign of George III. the new street there was called Eden Street. This locality is interesting to us, because Abercrombie, the worthy gardener, dates one of his books from Tottenham Court. Having taken a plot upon the estate near the main road, he carried on a nursery for several years bearing this title, until his infirmities obliged him to retire and become the occasional adviser of others. One of his fancies was to compose short pieces of poetry, which he put up here and there in arbours and upon walls, a line of things in which he has not had many successors.

The district of St. Paneras, with Camden and Somers Towns adjacent thereto, is not only bare of venerable trees, but of any memorials of such, and the historian of London suburbs describes it as a bare, unpromising region, chiefly grass land, only here and

there a market garden, but the side of one hill was set with fruit trees and trellised Vine. Railways and depôts, also an increase of houses, have so far polluted the air that gardening has become unprofitable, and I recently witnessed the clearing of one of the last plots at Camden Town upon which vegetables had been raised laboriously. As to the railway openings or cuttings, I may remark that some of these might be advantageously planted with trees or shrubs. This has, in a few instances, been done on the south side of London; probably evergreens are preferable to deciduous species. But of lesser open spaces accessible to the public this district is remarkably scant; the only two of consequence are the ground of St. James's Church, Hampstead Road, and the connected grounds of St. Paneras and St. Giles, a little further north. Situate in a populous district, formerly the churchyard of St. James's, is much resorted to, though its extent is but three acres. It presents a peculiarity I have noticed in no other suburban garden, that its asphalted walks are each distinguished by names and geometrically planned. The method is also followed, which is observable elsewhere, of placing in the centre of most of the flower beds some evergreens and herbaceous plants, and outside these a circle of bedding plants during the summer. When these are removed in autumn, as the centre is not touched the beds do not present that bare appearance which in some of these gardens is unpleasantly noticeable at the winter season. Though the dark December days were setting in, here, as in a few more of our London gardens, the Chrysanthemums along the borders still had some of their blooms unwithered, though tinged with the smoke, and flaccid from heavy rain. The trees, not numerous, in this open space, are comparatively young, and the kind most conspicuous is the Lombardy Poplar, lines of which have been planted in various directions. It is a tree which looks well up to a certain age in the London air, but after a time does not thrive as does the Black Poplar.

The larger ground of St. Paneras church comprises seven acres, and it is sufficient to furnish employment to four gardeners and a foreman. But the picturesqueness of this garden is marred by the circumstance, that as many of the old tombstones have been left, it still retains much of the churchyard look. Curiously suggestive of the link between this district and the iron regions of England are the rockeries placed here and there made up partly of fragments of brickwork and partly of slag. Upon these have been placed a variety of plants, but only such as do not need a constant moisture, for they are dry rockeries. A very abundant plant was the common Moneywort, and the familiar Saxifraga umbrosa (London Pride), suitable, because green all the year round in London. Some of the Heaths are specially suitable for such banks, though they will not always flower. In this ground the trees are not numerous. We find the Weeping Ash and the Willow, some Limes and Elms of moderate growth, and a few twisted Hawthorns. There are many evergreens, scattered, and in clumps. A pretty effect is produced in one part by a circle of Privet formed into a dense hedge, with inter-radiating lines of Thuias, Laurels, and other species. Some Yuccas showed signs of good progress made since they were put in, but, as is not unusual about London, Ferns refuse to grow satisfactorily.

On the slopes north of Oxford Street, formerly Bedford Fields, to which we have already referred, once resorted to by duellists and foot-pads, also visited, it is said, by the City damsels, for the purpose of gathering herbs to be used as cosmetics, there are now squares, occurring frequently, and giving a semi-rural character to the locality. In one instance we have several open spaces in approximation, by the joining of Brunswick and Mecklenburg Squares to the garden of the Foundling Hospital and an old burial ground. Largest of all is Russell Square, with its ten acres, deemed by some the finest square in London. Euston Square contains seven. This is interesting as having been an old nursery garden in the reign of George III. At present these squares are jealously "preserved," but they may some day become popular resorts. Having been formed in comparatively recent times they exhibit few trees of any age. Bloomsbury Square has a tradition of a remarkably graceful and tall Robinia which was cut down in 1800, and was supposed to have been planted by Lord Southampton soon after the Restoration. And the last of some old Pear trees, which had once been in the gardens of Bedford House succumbed to time about thirty years ago. In most respects these squares resemble each other. Elms, Limes, Ashes, and Planes predominate, a few Chestnuts and Birches mingling with these, and the familiar Lilacs and Laburnums, which one expects to see in every London garden of the old style. Such antique favourites amongst the plants as the Iris germanica, the common Golden-rod, and Dianthus barbatus are, however, yielding ground to the newer species. But I should like to see more freely planted about London the Coronillas, Hepaticas, Helichrysums, Enocheras, and other species I might enumerate, which will grow with proper management, even in poorish soil, and such as Ailantus glandulosa, Catalpa speciosa,

Sophora japonica, *Cerasus sinensis*, *Halesia tetraptera*, and many more of exotic parentage which might adorn our London open spaces.—J. R. S. C.

A NEW VEGETABLE.

IN 1887 attention was called in France to a new vegetable, which had been introduced from Japan under the name of Chiro-Gi.

It was shown at a meeting of the National Horticultural Society of France by M. Chappelier, and several writers in French periodicals described it as of a very promising character. The botanical name under which it first appeared in publications was *Stachys affinis*, but the authorities have since decided that it is distinct from the species named, and the appropriate title of *Stachys tuberifera* is now adopted. In France the popular name of "Crosnes" has become current; in England the name "Spirals" has been suggested as suitable, and now it is catalogued as "the Chinese Artichoke," though Japanese would perhaps have been more suitable.

Specimens were exhibited in December, 1887, before the Fruit Committee of the Royal Horticultural Society, by Mr. A. G. Hookings, gardener to Sir H. Thompson, Moulsey, who has grown it successfully, but it was regarded as little more than a curiosity. Since then it has been tried in the Chiswick Garden, where it has grown and increased with surprising rapidity, and though the tubers are small they afford ample compensation for this in their numbers. The plant is of bushy habit, a foot or more in height, with spreading fibrous roots, bearing the peculiar little tubers, somewhat spiral-like at first glance, but really formed of a series of fleshy rings, largest in the centre, and gradually decreasing to the extremities. They differ much in size, ranging from 1 to 3 inches in length, and averaging about half an inch in diameter, of a consistency resembling Jerusalem Artichokes, and it is said they are principally composed of inulin, the starch substitute found in the latter vegetable, though some have stated that in analysis they give 20 per cent. of starch.

Messrs. J. Carter & Co., High Holborn, exhibited tubers at a meeting of the Royal Horticultural Society's Fruit Committee, on November 13th this year, when the specimens were cooked and tried by the Committee, with the result that they were considered very satisfactory, and a first class certificate was awarded. Consequently the enlarged and handsome catalogue or Vade Mecum of the firm named for the year 1889, which is just issued, announces the plant for distribution as "a new vegetable," and gives an illustration, which we have been kindly permitted to reproduce in fig. 64. With this as with other vegetables much depends upon the way it is cooked and prepared for

FIG. 64.—CHIRO-GI.

table. Boiling, steaming, and roasting are recommended, and serving with melted butter; no doubt, however, several modes of preparation will be devised by skillful cooks.

This *Stachys* is of easy cultivation and ready increase, having proved hardy both in France and this country. A rather finely

pulverised fairly rich soil is desirable, in which the roots should be planted a foot apart in rows about double that distance asunder. One important point must be borne in mind—namely, that the tubers do not keep well after they are lifted, so that if removed from the ground they should be stored in some slightly moist material.

An analysis of the tubers of this plant is given at page 562 of this issue.

NOTES FROM A HERTS GARDEN.

ORCHIDS.—We do not attempt the culture of these plants beyond a few in an ordinary stove, in which respect we are in the same category with many others, who admire Orchids yet cannot devote a house or houses solely to them; and though we may not obtain such a wealth of flowers as some, yet there is satisfaction in being able to grow and enjoy the quaint beauty of these most interesting plants in ordinary structures. Although houses specially fitted up for Orchid culture may be desirable, yet the fact remains that many of the most beautiful, free growing, and floriferous, and most generally useful varieties do equally well, and in some instances better, in an ordinary stove, intermediate house, and greenhouse. Indeed, Orchids are as easy to grow as hardwooded plants; all that is wanted is a knowledge of their requirements applied with care and attention. Houses of *Odontoglossums*, of *Cattleyas*, *Vandas*, or *Dendrobiums* and *Cypripediums* are certainly attractive, but they lose more than half their charms by lack of suitable association. Have by all means houses to grow the plants in, but to display them place them where they will best enhance the interest and enjoyment of the spectator.

In December we have *Cypripedium insigne* and *C. venustum* in flower, which tell well amongst *Adiantums*, small *Palms*, and small *Dracenas*, of the highly coloured varieties, raised plants of *Calanthe vestita* are graceful, also some *Asparagus tenuissimus* and *A. plumosus nanus*, against which is *Calanthe Veitchii*, with its bright rose flowers and tall gracefully arching spike; a plant of *Oncidium flexuosum majus*, with a panicle 4 feet high, bearing hundreds of flowers, yellow spotted with brown, whilst the air is filled with the "sweetness" of *Zygopetalum Mackayi*. All these are common, and are consequently within the reach of everybody.

HELLEBORES.—The Christmas Roses have been with us since November. *Helleborus niger maximus* was the first to appear, its large white buds tinged with pink being very pretty; *H. altifolius* is similar if not identical; *H. niger angustifolius* has numerous flowers, large, and pure white; *H. niger* is also coming very strongly, and has abundant buds that will be expanded before the festive season; *H. atrorubens* is also in flower; its rich reddish purple flowers borne abundantly, contrast finely with the dwarfier form and white flowers of *H. niger*.

HABROTHAMNUS ELEGANS.—Every greenhouse and conservatory should have a plant of this, which is good either as a pillar or roof plant, and is good also for walls, but it is necessary that it have plenty of light. Grown in a pot it is fine for decorative purposes, flowering in late summer and autumn when flowers are not too plentiful. It is readily increased by cuttings of the half-ripened shoots in July or August, in a close frame either with or without heat, but they root sooner with gentle bottom heat. Repot the plants as the roots extend, not giving large shifts, but keep the plants near the glass to insure sturdy thoroughly solidified growth. Pinch back the growth to a few joints of its base by early February so as to induce a bushy growth, and give the largest pots when the plants have made a few inches of growth, affording liquid manure after the pots are filled with roots. After flowering let them rest awhile, cut the shoots back to two or three joints from the old wood in January, turn them out and remove about a third of the ball when the plants have made an inch or two of fresh growth, and return to the same size of pot, in which they may flower, feeding after the fresh roots have possession of the soil, or they may be shifted into larger pots. Fine plants may be grown in 9 and 10-inch pots. Good loam, with a little leaf soil or well-decayed manure suits these plants, good drainage being essential. The plants must not be watered until it is necessary, but when needed a thorough supply should be afforded.

Planted out in a border of good loam enriched with leaf soil or well-decayed manure and efficiently drained, it grows freely and makes a fine specimen for a wall not shaded, a pillar, or a short roof, planting firmly, as upon the sturdiness of its growth depends the density of its cymes and substance of the flowers. In a loose and siliceous soil it grows freely enough, but the cymes are small and the flowers poor as compared with those of plants grown in a rather strong and firm soil. It may be mulched with short manure or be given surface dressings of

artificial, and in August onward—ours is now (December) in full beauty—its numerous dense terminal heads of bright purple-red flowers make a display that cannot be readily surpassed. When fully grown it merely requires spurring in in early spring, young plants being shortened to firm wood so as to insure the needful growths for furnishing the space.

APONOGETON DISTACHYON.—During the mild weather of November and early December this very ornamental and free flowering aquatic was in fine flower in tanks outdoors, the flowers being remarkably strong and eight expanded ones on a plant, with a quantity of buds showing, but it cannot stand frost, a few degrees irreparably damaging the flowers. It is, however, perfectly hardy in 18 inches depth of water, seeding and increasing freely by that means and offsets. Indoors it flowers through the winter, and does not require a large area nor a great deal of soil; in fact, a vessel 2 feet across and a foot to 18 inches deep with 3 or 4 inches depth of soil, loam, and leaf soil or cow manure will accommodate a strong specimen, and it is the strong plants that give the large flowers from September through the winter. It requires plenty of light and air. Its white bracts and delicious Hawthorn-like perfume render it very desirable as a winter flowering plant for the greenhouse. Though it flowers under favourable conditions nearly all the year round, yet in warm situations it flowers most freely in autumn, whilst in the more breezy and colder situations the flowering is in early summer.

AQUATICS FOR TABLE DECORATION.—What is so charming as an oval glass bowl 2 feet in length, 18 inches in width, and 3 or 4 inches deep, filled with clear water and *Nymphaea alba* foliage and flowers as a centre? Intersperse with these the rosy-pink variety *N. alba rosea*, and raise outside all round to the level of the dish or a little higher with green or fresh sphagnum in which are plants of Sundew (*Drosera rotundifolia*), or failing those any small bog plants foliage and flowers in green moss. Lesser bowls may be used for *N. odorata* and its charming variety rosea, pale pink. Smaller dishes may be used for the corners, and for a long table up the centre. If plants are used let them be such as *Cyperus* and *Isolepis*. *Aponogeton distachyon* in small dishes with its own foliage, floating leaves, is about the only available winter plant, but in summer there are more to choose from. *Villarsia nymphaeoides* leaves and its flowering sprays are pretty.

ROSE MADAME FALCOT.—Mentioning table decorations reminds me of this Rose so charming in buds which are now produced freely by a specimen planted out in a conservatory and trained at the end of a stove which adjoins. It is freely exposed to light, as there are no climbers overhead in that part; in fact, the Rose reaches to the roof, and is suffered to grow rather informally, which adds to its appearance and to the freer production of its lovely buds.—**UTILITARIAN.**

REVIEW OF BOOK.

The Practice of Forestry. By CHRISTOPHER Y. MICHIE. William Blackwood & Sons, Edinburgh and London.

MR. MICHIE, the forester of Cullen, the seat of the Earl of Seafield in Bantishire, has had great experience on the subject on which he writes, and this handy book will be serviceable to many who are interested in tree planting and management. The author, with the object of adding to the usefulness of the work, does not exclude from its pages the experience of others, duly crediting them with their productions. We are going to follow his example, for a citation will answer some questions that have reached us, and the information will be acceptable to many.

After showing that land estimated at 15s. per acre as poor pasture when planted with trees will over a term of years yield a net annual income of £4 10s. an acre Mr. Robert E. Brown says:—

"Five years ago I received the management of about 400 acres of plantations on the estate of Wass in the north of England. The estate was owned by a thoroughly enlightened gentleman, who was anxious to have the woods put into good condition. During the last five years we have endeavoured to improve the woods properly, and the result is the improvement of the plantations to an amount fully twice the value they were at first, after taking from them a regular income, in the shape of thinnings, every year. These plantations have been giving an average yearly income since 1861 of £2 10s. per acre net, and similar land on the estate is let with difficulty at 10s. per acre.

"One instance, in particular, will show the increase of value of woods when under a regular course of thinning. A wood, consisting of a crop of Oak and Ash, extending to 100 acres, was valued in 1864 by several foresters and timber merchants at £4000; since then thinnings have been taken from it to the amount of nearly £2000, and in the present year (1866) I am offered £5000 for the standing crop.

"I consider thinnings of very little value before the plantation reaches the age of fifteen years—all that is required up to this time is a careful going over, cutting out any dead wood, and relieving any healthy

tree that requires it. I believe that most of our woods at the present day are ruined by overthinning—the result, first of the want of trained men; or second, where experienced men are employed on an estate, the term of their management is so uncertain that they aim more at having a good balance in their favour at the end of the year than securing the ultimate success of the plantation. I strongly recommend that no healthy tree be cut until it has attained a marketable value. The great aim of forestry should be to secure the highest possible return from the ground, and nothing adds more to this than length of scantling. Length is the principal object, and can only be attained by preserving a closeness of trees on the acre. When I say a closeness of trees, I do not mean that one tree should interfere with another, knowing that the two things most essential to the growth of trees are root and branches. Quality, nowadays, is subordinate to quantity, and there is a danger of placing too high an estimate on the value of thinnings and too little on the crop remaining for the final cutting. The final cutting should never be less than eighty trees per acre if Larch, and nearly two-thirds more if Scots Fir."

"Supposing that 2500 Larches and 1500 Scots Firs have been planted per acre, the thinnings might realise as follows:—

First thinning, at fifteen years—

Larches, 600, at 2d.	£5	0	0
Scots, 300, at 1d.	1	5	3
900				£6	5	0
Cost of cutting, 3s. 6d. per 100		1	11	6
				£4	13	6

Second thinning, at eighteen years—

Larches, 300, at 3d.	£3	15	0
Scots, 200, at 2d.	1	13	4
500				£5	8	4
Cost of cutting, 4s. per 100		1	0	0
				£4	8	4

Third thinning at twenty-two years—

Larches, 500, at 6d.	£12	10	0
Scots, 300, at 3d.	3	15	0
800				£16	5	0
Cost of cutting, 6s. 6d. per 100		2	12	0
				£13	13	0

Fourth thinning, at twenty-six years—

Larches, 500, at 1s.	£25	0	0
Scots, 200, at 6d.	5	0	0
700				£30	0	0
Cost of cutting, 8s. per 100..		2	16	0
				£27	4	0

Which gives for the four thinnings an expenditure of £7 19s. 6d., and an income of £57 18s. 4d. There will remain 600 Larches and 500 Scots Firs, or 1100 trees; but allowing for 300 failures and removals during the first fifteen years, there are still 800 per acre. This is the number of trees I begin with as the real crop to operate upon, which I consider very near the right quantity."

Our experience in the cultivation of Larch is corroborative; some plantations proved so satisfactory that much sandy land devoted to farming was planted a few years ago, and from the present time onwards the annual sales will realise sums fully justifying the change of culture. What was known as "bad" land on the estate has proved more profitable occupied with Larch over a term of thirty years than has the best land under tillage let at rents varying from 30s. to £2 an acre. There can be scarcely any doubt that there are thousands of acres of almost worthless, because neglected, plantations in this country which might be rendered profitable by judicious planting and management. This is an important subject, and not the less so since purchasers of English timber tell us it is almost certain to become dearer in the future than it has been in the past.

Intending planters may consult Mr. Michie's works with advantage, as he gives information founded on long practice on almost every point connected with the subject.

PRUNING EVERGREENS.

A FEW notes on the subject of cutting-in evergreens of various kinds may be useful to those about to operate on these ornamental features of a garden or landscape, and especially on large full-grown specimens which have not previously been subjected to much cutting-in. As this is the class most difficult to manage well it will be necessary to consider the condition and nature of the plant before we commence too rashly to use the knife, axe, and saw.

Very little consideration will convince us that an evergreen of

large size cannot be entirely cut down without inflicting on it great injury, and possibly the operation may kill it; but although a total deprivation of foliage may be fatal, the removal of one-half or even more of it may not be so: consequently, when a large Laurel or other shrub has so far outgrown itself as to be no longer ornamental, becoming naked at the bottom, or otherwise unsightly, partial cutting-down is essential to appearance, and when it can be so managed as to leave some of the lower branches well clothed with foliage the energies of the plant soon repair the disaster. Perhaps of the shrubs which show most conspicuously the utility—nay, almost necessity of this plan—the Arbutus is as good an example as any. The part that was left may also be cut away in about two years afterwards. Phillyrea, Laurustinus, and some other shrubs generally succeed well under this treatment, the common Laurel especially so, and the Portugal Laurel does as well when thus treated as in any other way, but it is a plant rather impatient of cutting-in, although in every other respect amongst the hardiest we have.

Perhaps the best time for cutting-in such evergreens may not be that adopted by us, but as it answers very well, and is attended with some advantages, there seems to be no objection to it. The beginning of April is the season at which we usually do such work. However well the cutting may be accomplished there cannot be any difference of opinion about the plant operated on looking badly for a time; and, as it is advisable to reduce that period to the shortest possible space by not cutting the plants until shortly before they will continue to grow again, they are not long in a naked condition. I do not, however, affirm that they are any better when left till April. For the reason already given, observe in all cases where possible to retain some branches with leaves on, even if such branches have to be bent to the ground to hide their unsightliness. After the rest of the plant has grown for a year or so these old branches may be cut off if necessary.

Laurel and other hedges of a formal and regular character ought to be cut with the knife, especially shrubs with large leaves, like the Laurel; but when this cannot be done the shears may be employed. In the latter case it is best to cut the common Laurel, and I believe most other shrubs of a similar description, early in June, just before the growth is completed, so that a second crop of short shoots may be formed. This takes off the appearance of close raw cutting and hides the deformity caused by cut leaves. For many years we have been in the habit of adopting this plan, and it is rarely indeed that the second shoot does not ripen itself, and it is seldom more than 3 or 4 inches long. Any longer or unsightly shoots may be cut out with the knife before winter, so as to allow of the hedge, bank, or whatever is cut looking uniform during the winter. Judiciously done, taking off sprays for Christmas decoration does no harm to the shrubs.

Choice evergreens against walls may be treated differently, as their flowering is of consequence as well as their appearance. The common Ivy when growing luxuriantly requires trimming; excepting in special cases we have found a severe cutting-in about the end of July, so as not to show a single leaf, resulted in the production in a month or six weeks of new foliage, which remained good all winter. When the Ivy is not so robust it is better, perhaps, to cut it in at the end of March. There is then a greater certainty of its doing well afterwards; but if it grow vigorously it will have projected a long way from the wall by the end of summer, and some cutting-in with the knife may be necessary in autumn. For this reason I prefer summer cutting as furnishing a more lengthened period of trimness.—C. E.

FRUIT CULTURE IN CALIFORNIA.

It is now generally recognised that California is one of the most favoured countries for extensive fruit culture, and much has been published bearing on the subject. The quarterly report of the San Jose Board of Trade, however, just to hand contains so many particulars of an interesting character that we venture to reproduce some extracts. The report specially deals with Santa Clara County, which is thus described:—

"The county of Santa Clara has an area of rather less than one million acres. Of this about 250,000 acres is valley—the ancient lake bed, or the alluvial deposits of existing streams; 300,000 acres is rolling hills and mountain slopes, well adapted to fruit; the residue, valuable principally for pasturage. While the general contour presented by the valley is that of a level plain, it is in fact a series of gentle undulations, with marked variations in the quality of the soil. In what is now, or has recently been, the lower portions of this plain, the soil is a black, tenacious clay, known as "adobe." It is very fertile and productive, but requires much care as to the time and manner of cultivating it, and is well adapted to hay and grain. The higher lands of the valley are a light loamy, and sometimes gravelly soil. This is easily cultivated, and is well adapted to all the cereals and to most varieties of fruit. In the vicinity of the Bay there are many thousand acres of salt marsh. No effort worthy the name has been made to reclaim them, though the task

would seem a not difficult one. It is safe to predict that at no distant day these lands will be reclaimed, and among the most productive and valuable in the county. The warm belt is a tract upon the slopes of the hills that environ the valley. It has an altitude of from 2 to 800 feet. It is generally—and in some localities wholly—free from frost. In this belt, to the east of Milpitas, Potatoes, Peas, &c., are grown through the whole winter for the San Francisco market. Upon the Los Gatos and Guadalupe rivers are some hundreds of acres, formerly dense Willow thickets, but now in the highest stage of cultivation. These lands are regarded as the most desirable in the valley. The soil is a sedimentary deposit, easily cultivated, requiring but little irrigation, and producing every variety of fruit and vegetable. Thirty miles south of San Jose is the town of Gilroy. The soil of the valley is here fertile and productive. Over a considerable portion the subterranean moisture maintains the growing pastures throughout the year, and some of the most successful dairies in the State are here established. The more elevated parts of the valley and the slopes of the hills are well adapted to fruits and Vines. The summers of Gilroy are warmer and drier than in San Jose. The cool winds from the Bay are materially softened as they sweep down the valley, and the differences of temperature between the day and night are not so marked. The air is mild and balmy, and the nights agreeably cool and pleasant.

"The watercourses within the county greatly diminish, when they do not wholly disappear, in the summer. Sinking as they approach the valley, they augment the subterranean resources which supply the artesian wells. These are found all over the valley. They are usually from 60 to 100 feet in depth, though some find a larger and more permanent supply at a much greater depth. The water is raised by windmills into tanks, and is ample for household and gardening purposes. About Alviso, and near the Bay, hundreds of acres of Strawberries and of vegetable gardens are irrigated from these wells, and the water rises to the surface with such force that the most massive appliances are required to restrain the flow."

Very elaborate tables of temperature are given, from which it appears that the mean for the year is 57°, the highest temperature registered having been 93° in September and the lowest in April, 28°, the average rainfall being about 9 inches in the year.

Turning the chapter on fruit culture we have the following particulars:—

"The basis of the past, present, and future prosperity of Santa Clara County is its agricultural resources. These resources depend on the fertility of the soil and congeniality of the climate. The experience of years demonstrates that the soil contains all the elements essential to plant growth, while the climate is of a character that insures the perfect maturity and ripening of its products. Before the American occupation stock raising was the principal business of the valley, and immense herds were fed on the nutritious grasses that grew spontaneously everywhere, in the valleys, foot hills, and mountains. With the American came the grain-growing industry, and the rich soil, the deposit of centuries, yielded crops almost beyond belief. Many instances are on record where immense fields have produced a hundred sacks of Wheat to the acre, each sack containing from 110 to 135 lbs., equal to an average of about 200 bushels to the acre. These crops were grown year after year with a superficial cultivation that reached scarcely 4 inches under the surface, while all below that was undisturbed and its fertilising elements untouched. The roots of the plants lay near the surface, and the yield of grain was not unfrequently diminished and sometimes totally destroyed by drought; but so great was the fertility of the soil that if a fair crop could be obtained once in three years it was a fortune to the farmer. Even now, with fair cultivation the Wheat fields yield from 30 to 50 bushels per acre, while the cost of planting and harvesting is only about 60 per cent. of what it is in the Eastern States. But the era of growing grain for profit in this county has passed, and the great Santa Clara Valley and the foot hills and mountains surrounding it has met its destiny in the fruit and Vine industry.

"An acre of ground that formerly produced from twenty to thirty dollars now brings a net profit of from 150 to 500 dollars. The history of horticulture in Santa Clara County is some excuse for this misunderstanding. The first considerable rush of immigration to California was caused by the discovery of gold. The people came to mine and not to plant. They were consumers of agricultural products, not producers. Everything that could be eaten sold at enormous prices. A few Apples that were imported sold from one to three dollars each. Some people of horticultural instincts saw in this circumstance a road to wealth. They planted orchards, and made money. Others caught on to the idea and planted more orchards. These trees came into bearing before there were people enough in the State to consume the fruit. There was no way to get it to market, and consequently no sale. It was a clear case of over-production. Many orchards were neglected and allowed to perish, others were dug up; but a few were maintained. The effect of this speculation was to impress the minds of many that fruit-growing in California was a dangerous experiment, and this impression still lingers in the minds of some of the old timers, who cannot understand the changed conditions which this country has experienced in the last thirty years. Then we were isolated from the world; we grew but few varieties of fruit—principally Apples and Pears—and our market consisted of the handful of people who lived within our limits. Now we have rapid transportation to all parts of the world; we grow all the desirable fruits known to horticulture; we have learned to grow them to a perfection attained nowhere else on the globe, and to cure them so that while retaining all their flavour they are practically imperishable.

(To be continued.)

FRUIT FORCING.

PEACHES AND NECTARINES.—*Early-forced House.*—The buds of these trees are swelling freely; 45° should be the minimum temperature on cold nights, between that and 50° being ample even on mild nights, with a rise of 10° to 15° by day from sun heat. Nothing is gained by undue haste until we have increased light and length of days. Peach blossoms allowed to unfold in a low temperature, particularly at night, with free ventilation, always set and the fruit stone well. Good crops will in a higher temperature, by which means time lost at the commencement is redeemed, the trees make strong short-jointed wood, and with due attention to thinning long remain profitable. Large crops of Peaches are only the forerunners of disaster, as Peach trees, like other fruit trees, are only capable of maturing a given quantity or weight of fruit, and if overcropped they do not exceed that weight in the aggregate, consequently the extra quantity is obtained at the expense of size and quality. Cease syringing as soon as the flowers open, but maintain a genial condition of the atmosphere by damping in the morning and afternoon of fine days. Raise the temperature early in the day to 50°, and not exceeding 55° from fire heat, and admit a little air, yet not to lower the temperature below 50°, and increase the ventilation with sun heat, having it full at 65°, and gradually reduce it with the declining heat, closing for the day at 55°. A little ventilation should be provided constantly at the top of the house.

Successional Crops.—Where there are three or more Peach houses annually forced the second should be started not later than January 1st; or where the early varieties such as Alexander obtain, and Hales' Early are grown, with Royal George for succession, this may be the earliest forced house in which fruit can with certainty be had in May of Alexander, followed by the others named in June without having recourse to hard forcing. If the house has been open to receive the autumnal rains the borders may be in good condition—that is, thoroughly moist to the drainage; but if there is any doubt about this an examination should be made, and if necessary repeated soakings given, so as to thoroughly moisten the soil in every part, and if the trees are weakly liquid manure may be given. It has been a prevailing practice to allow the inside borders to become dry through the autumn and early winter months, but it is a mistake that is often followed by the buds falling, and the disaster is frequently attributed to every cause but the right one. With the borders of suitable material resting on ample drainage there is little danger of their receiving too much water either by exposure to the autumn rains or by giving liberal supplies from the tanks. Fire heat will not be necessary for the first fortnight except for excluding frost, and the house should be freely ventilated when the temperature reaches 50°.

Later Houses.—The cleansing of the houses and trees should be proceeded with as opportunity offer. Where the trees have been infested with insects, such as red spider, scale, and brown aphid, it is desirable to syringe them before untying with a solution of soft soap, 2 ozs. to the gallon of water and 1 oz. of soda to 4 gallons, adding a wineglassful of petroleum; the solution to be kept mixed whilst it is being applied to the trees and house, which should be done thoroughly, wetting every part. When dry the whole may be syringed with water at a temperature of 140° to 150°. The trees will then be very bright, and the cleansing of the woodwork with soap and water and the glass with clear water facilitated. The walls should be lime-washed, and the loose surface soil removed, adding rather lumpy loam with some steamed bone-meal or other approved fertiliser. This will stimulate the surface roots and encourage active feeders by the time the blossoms are expanding. Prior to this the trees will have been pruned and re-arranged and tied to the trellis. If the roof lights are fixed, ventilation should be given fully, the trees being afforded rest as complete as possible, care being taken not to allow them to become dry at the roots. If the roof lights are moveable, and have been removed, they may remain off until the time arrives for starting the trees or until the buds commence swelling, when the sashes must of necessity be replaced to insure the safety of the buds and blossoms.

UNHEATED HOUSES.—We have hitherto been in the habit of withdrawing the roof lights as soon as the leaves had fallen; but this year, owing to the cold season, the wood is not so ripe nor the bloom buds so plentiful or so well developed as to render it advisable in our opinion to remove them. Therefore we shall keep the lights over the trees, and moderate the ventilation by day when the sun is bright, so as to induce the hardening of the wood, and ventilate freely at night and in mild weather to promote evaporation and increase the firmness of the wood. By maintaining a dry atmosphere it is anticipated the wood will not be injured by frost, as might be the case were the trees fully exposed. Trees in this state rarely have the bloom buds sufficiently advanced as to cause anxiety of their falling when the trees are kept somewhat drier at the roots than under ordinary circumstances would be inexpedient. Besides dread of the wood and buds not being sufficiently ripened to set and develop the fruit satisfactorily, there is cause to apprehend mildew, which attends immature wood—i.e., the growths that proceed from it

and is the chief cause of blistered leaves. To still further assist the tree-ripening the wood we have had them dug round and the strongest roots detached at one-third the distance from the stem the trees cover of trellis, so that by reducing the supply of sap the wood will not be so gorged on a sunny day as to be liable to injury from frost in severe weather.

THE FLOWER GARDEN.

Keeping Bedding Plants.—A long spell of mild damp weather often causes the loss of more bedding plants than is the case frequently in frosty weather. Especially difficult to keep are the Zonal Pelargoniums in boxes, pans, and large pots, stored in cold or but little heated pits and houses. Damp is the worst evil to contend with, and in order to counteract it all should be kept as dry as possible, given good room as well as plenty of ventilation, and have all decaying leaves removed from them. Fire heat accompanied by night and day ventilation dries and hardens the growth, prevents damp, and renders the plants less liable to be injured by frosts. Lobelias, young Ageratums, Heliotropes, and Verbenas ought not to be kept very dry at the roots, and these keep well on the shelves of a greenhouse or near the glass in other slightly heated structures. Alternantheras, Coleuses, and Iresines ought to be stored on shelves in the plant, stove or forcing houses, and not kept dry at the roots. The greenhouse shelves or stages are most suitable positions for choice succulents, and these must be kept dry. Give Calceolarias, Violas, Gazanias and other bedding plants in frames all the air possible, the aim being to check weakly growth. Plenty of dry litter and mats ought to be in readiness for covering the frames and pits whenever severe frosts are imminent.

Early Chrysanthemums.—Only the earliest or summer flowering varieties gave a good display this season, the successional and late-flowering being much crippled by frosts in October. Most of the latter are usually also flowered in pots, and in this case sufficient stock plants are kept to afford cuttings both for pot and open air culture. The summer and early autumn flowering varieties, which include La Petite Marie, St. Mary, Mrs. Cullingford, Fiberta, Frederick Pélé, Madame Piccol, Mdlle. Jolivart, Précocité, Yellow Petite Marie, Alexandre Dufour, and La Vierge, are not so generally grown in pots as they deserve to be; unless, therefore, a few strong plants of each are lifted and either potted or stored in frames surrounded by common soil, and lightly protected from severe frosts, the stock may be lost. All are fairly hardy, but in cold wet soils especially they are liable to perish, and in any case the slugs are apt to eat every young shoot that appears. Lifting and storing as advised, either in pits, frames, or cool houses, is the surest method of preserving them, but if this is not practicable the least that can be done is to well mound up each plant with coal ashes, this protecting from frosts and slugs. It is advisable to strike cuttings every spring, young plants giving better results than old stools.

Roses.—In open weather the work of planting these may continue. Those that have long been in one position are much benefited either by a change of site or by being replanted in fresh soil. Many of those well established on their own roots may frequently be divided with advantage, this being the readiest method of increasing the stock of Souvenir de la Malmaison and such serviceable varieties. Plant rather firmly, stake if needed, and mulch with strawy manure. Standard Roses are the first to succumb to frost, and strange to say the Briar stems are the most vital part of the plants. In very unfavourable districts, or where extra severe frosts are experienced, it is frequently necessary to bandage the stems with hay, straw, or bracken, and the large or principal stems of Maréchal Niel and other choice climbing Roses need similar protection even in districts where Roses are considered quite hardy. Owing to the exceptional mild weather that has long prevailed Roses are still active, and are therefore more liable to injury than usual. Snow is a capital protection to dwarf bushes, but this is not always present when most wanted, and those who value their bells or single bushes ought to have plenty of strawy litter or bracken in readiness for protecting them. Sufficient of this should, when a severe frost is threatened, be loosely distributed among the plants so as to cover them to the point where the young shoots will be pruned next spring.

Work in the Pleasure Ground.—The late autumn months have been most favourable to the work of levelling and re-turfing lawns, as well as thinning old or forming new shrubberies. When this has to be delayed till the spring cold drying winds are apt to injure the roots, and also cause the foliage of evergreens to flag badly, and if transplanting Hollies is excepted, it is better for various reasons to push on the alterations and tree moving now than have to do it in the spring, when so much other work requires attention. Collect a large heap of leaves and store either above ground or in pits, and when duly converted into leaf soil this will prove of the greatest service for mixing with either planting or potting soil. It is also advisable to turn over the heap of sweepings, road trimmings, lawn grass, and other rubbish that has accumulated, and if the sticks are thrown out and burnt, and the ashes returned to the heap, a valuable compost will be the result.

KITCHEN GARDEN.

The weather throughout the autumn and until recently has been much in favour of vegetable crops. Cauliflowers have been very plentiful, and just before the frost came we stored ten dozen heads, which will tide us over the next two or three weeks. Broccoli would perhaps be the usual term to apply to these, as the variety which has been doing such good service is Veitch's Autumn Self-protecting Broccoli, but it is so

like a Cauliflower in its beautiful white heads that this name is appropriate.

SOWING PEAS IN AUTUMN.—Some growers sow a few rows of Peas in autumn, but these are by no means the majority or so numerous as they ought to be, as autumn-sown Peas if properly treated will furnish pods before any sown in spring. If sown at this time they invariably grow robustly and remain strong and healthy during the spring months. We have tried them in all the weeks from the 1st of November until the last of December, and always sow some in the week including the shortest day. Only the earliest round-seeded sorts should be sown now. The position must be sunny and sheltered, but not too much confined. Cold strong winds are more injurious to them than severe frost. We prefer sowing on a south or south-east border, the rows not being closer than 10 feet apart, as it is important that the sun in the early summer should reach all parts of the rows. We rarely manure a whole border or quarter for Peas, but dig a quantity of manure in where each row is to be sown, and after digging the drills are opened for the seed with a drag hoe. These are not made so wide as in summer, as the young plants do better when close together than when thin and far apart. Make the drill 4 inches deep; and after sowing the seed put 3 inches of soil on the top, and finish with 2 inches of finely sifted ashes. These make an excellent surfacing, as they do not retain the moisture about the young plants like soil, and they also guard them very well from snails. Should the soil be moist at sowing time do not tread it, but as soon as it is dry tread it down each side of the row, as Peas grow much better in firm than in loose soil.

BROAD BEANS.—These should also be sown now, large-podded varieties being avoided at present. They will succeed in a colder and heavier soil than the Peas, but shelter and sun are highly beneficial to them. Sow the seeds at the same depth as the Peas, and not more than 2 inches apart. Mice are very fond of Broad Beans, and care must be taken from the first that they do not injure the seed.

HOTBEDS.—In a week or two hence the forcing of Carrots, Radishes, Potatoes, &c., will demand attention, and hotbeds afford excellent means of growing them. These early crops are invaluable. Material, therefore, must be collected at once, and may consist of tree leaves and littery manure from stable or cowshed. Vegetable refuse, if fresh, may also be employed, but reject half-decayed matter, as it will not retain the heat for long. Throw the whole into a large heap to ferment, and to allow the excessive heat and moisture to escape, turning the material every alternate day for a fortnight, when it will be in good condition to make into beds that will retain warmth for three or four months.

HORSERADISH.—This is not a leading crop, and yet it is almost indispensable, but a small plantation is generally sufficient for an ordinary supply, and this may be secured without much expense. We are never very anxious to have Horseradish of extraordinary thickness. Roots an inch or two thick suffice, and are easily produced. The best way of transplanting is to dig the whole of it up, select a number of straight young roots for replanting, and lay all the others under the soil in an odd corner for use as required. In replanting dig the soil to a depth of 15 inches, adding a quantity of manure if necessary, and replant by making holes with a dibble and dropping the thong-like roots in. The crowns should nearly be level with the surface, allowing a space of 2 feet between the rows and 15 inches between the plants.

STORED ROOTS.—These are not keeping well. Onions, which appeared matured, are sprouting, so are Potatoes in sheds, and all should be examined.

PLANT HOUSES.

Chrysanthemums.—Intending growers of large blooms should insert cuttings without delay. They will root freely in sandy soil in a cold frame, or better still in a frame or under handlights in a cool house from which frost is excluded. For this purpose select sturdy cuttings that have sprung from the base. We prefer inserting the cuttings singly in small pots and then standing them in a frame or under handlights. Water liberally after insertion, and if the lights are kept close the cuttings will not be long before they are rooted. Directly they are rooted gradually harden them to a cool temperature.

French and Fancy Pelargoniums.—Be careful not to give these too much water or their foliage will become spotted. On the other hand, do not allow the soil to become dust dry. Keep the atmosphere of the house as dry as possible without the aid of fire heat. This can be accomplished by having a little fire heat on fine days, when the structure can be ventilated liberally. Maintain a temperature of 45° at night, which will be ample to keep the earliest plants advancing slowly, and if they are advanced near to the glass the growth they make will be sturdy. Aphides are very likely to attack the plants at this stage of their growth. If they are observed fumigate the house slightly with tobacco.

Cyclamens.—If these are not coming into flower as quickly as desired place them on a shelf near to the glass in a temperature of 50° to 55°. Under these conditions they will quickly push up their flowers. Ventilate on all favourable occasions to prevent the foliage drawing. Young plants that were pricked into pans and boxes two months ago may now be potted singly into 2-inch pots. Encourage a slow but sturdy growth in a temperature of 50°. When young plants are grown on in brisk heat they become drawn and seldom do well afterwards. Prick out seedlings into pans or boxes. To succeed with Cyclamens never allow the soil to become dry from the time the seed is sown until after the plants have flowered.

Hydrangeas.—Where these were rooted in small pots and have been

kept in them until now they can be placed in 5-inch pots as opportunities offer. Those rooted from plants that failed to flower early in the season will have enjoyed a good rest, and may be started into growth directly they have been potted. A vinery, Peach house, or Rose house just started is a capital place for them. In potting be careful to leave the bud above the surface of the soil. This season we are potting in every case where practicable as low as possible; the pots will be filled up after the flower is visible. This will insure good foliage down to the rim, and will assist the blooms wonderfully when developing. Use for a compost good fibry loam, one-seventh decayed manure, and a little sand.

Lilium candidum.—Where these were potted as early in the season as bulbs could be obtained, and have since been in cold frames, they can now be removed to a light airy structure where the temperature will range about 45°. Undue forcing must be avoided, but under the conditions advised the flower stems will soon be visible. Allow them to come forward steadily; if hurried they will fail to flower. Watch for aphides, and destroy them at once if they appear on the plants. As growth advances supply water liberally.

THE BEE-KEEPER.

NOTES ON BEES.

CANDY FOR BEES.

EVER since this Journal first announced the advantages of feeding bees with barley sugar, volumes have been written upon the subject, and candy, in consequence of its less liability to deliquesce than the former, has been substituted. A reader of this Journal, "W. H. C. D.," sends the following recipe for feeding neglected bees:—"I have made several cakes of candy for the bees, simply by damping granulated sugar with water, putting it in a shallow box, and setting it near the fire to harden into a cake; it answers splendidly, and this is much easier than boiling, and no risk of burning." The above plan seems much better than the common candy, as there is no waste of sugar by the bees, nor through the change brought on by boiling. Then the "shallow boxes with a moveable lid to fall in as the bees take the sugar is ingenious and good. The same writer also states that he has a large surplus of honey from all his hives, made and managed according to instructions given in this Journal, but not an ounce from the ten-framed standard size of the British Bee-keepers' Association, and wisely adds that in a good year honey may be had from any hive; but in a bad season it can only be had from hives such as has been recommended in these pages, and proves conclusively what is the best hive."

RAISES UNDERNEATH HIVES.

At page 549 I incidentally mentioned the uses and the antiquity of these raises, and in a former article showed that the system was being tried in this country as an entirely new one. I have also shown how numerous old ideas have been appropriated by others of the modern class, and how the Americans have of late been only advancing for the first time these old ideas. Singular to say, "Gleanings," that came by the same post as the Journal, contains a description and drawing of a raise as new, exactly the same as has been in use hereabouts from time immemorial; and yet we read in the same "Gleanings" that they, the Americans, were the most advanced bee-keepers in the world. If America is not more fatal to bees than our country is during winter I cannot endorse such statements, for until bee-keepers know how to preserve at least ninety out of every hundred of their hives during winter they are far behind. If all would give the ventilating floor a fair trial, many hives that are allowed to perish during winter or smothered during summer's heat, would be preserved alive.

GLASS SECTIONS.

I have no less than a score of letters asking my opinion of these as well as many others on different subjects, most of which I have, through pressure of work, been unable to answer, but will do so at the first convenience, so trust this explanation will be a sufficient apology.

I can scarcely give a proper estimate of these Hallamshire sections. The fact is that many having attempted the making of these and failed, myself amongst the number, and all the more credit is due to "A Hallamshire Bee-keeper" for his plan and success in being the first to produce a filled glass section. I bought a bottle of cement with the intention of making glass sections. It was warranted to hold and bind everything together; but alas! "vain are the hopes." My first trial with the cement was with two united pieces of glass in my pocket giving way while in my vest pocket. I have often thought, however, of bending pieces of glass, by heating them at first in a furnace and bending them on a heated square of iron, but never put it to a good trial. Doubtless glass, although it may not be generally used, will, as of yore, continue to be used by many bee-keepers as attractive specimens of honeycomb, and I feel certain that when "A Hallamshire Bee-keeper" announces his intentions of revealing his plan of making glass sections, and many will be grateful to him for the desired information.

Glass both above and below supers has been used for upwards of a century, and Messrs. Neighbour carried it so far as to introduce all glass hives, probably the first to do so with hives not unieomb ones; but although glass has been so used, and for so long, "A Hallamshire Bee-keeper's" idea is the latest one, while those who are now trying to appropriate the idea as being first in the field to use glass as sections or part thereof, are but copyists after all.

HOW TO WORK SUPERS.

It is of far greater importance to know thoroughly how to understand the working of supers or sections than to quibble over this or that material. In my last article some hints were given, but not all. Sections or supers divided into compartments do not yield the same amount of comb as those do of one compartment only—i.e., when any number of supers can be placed on the hive as one, each bee getting access to every part. Sections suspended to a bar gives this advantage, and many others, while they do not obstruct the entrance of the bees. Small supers which I have already spoken of, and which may be had from 4d. to 7d. per dozen for material, ought to have a portion of the underside inside sides of about half an inch removed with a cutting guage (these can be attached after they are filled), this need only be done to those of the bottom tier, which is sufficient for the purpose. These small supers are made to hold from 2 to 5 lbs. each, and are easier managed and cheaper than sections, and require less expense decorating for the market, which, owing to the increase of bee-keepers and honey, is rapidly becoming of less value, which does not justify unnecessary outlay in decorating, as is commonly practised with sections. I am of opinion that it is a mistake to encourage honey producers to be at so much expense in preparing sections for market, such as glazing, decorating with paper, and packing cases for single sections. If such is necessary, it ought to be done by the retailer. Honeycomb when of good quality is its best decoration, and it requires no other. The only thing absolutely necessary is to have the sections or supers as clean as possible, and if this economical way of putting honeycomb on the market does not suit, then it may be safely said that bee-keeping for profit is a failure. "Are bees worth keeping in this country with so changeable a climate?" will be answered in another article by—
A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Stansfield Bros., Southport.—*Illustrated Catalogue of Alpine and Hardy Perennials.*

Sutton & Sons, Reading.—*Amateurs' Guide in Horticulture in 1889 (Illustrated with Coloured Plates).*

Carter & Co., 237 and 238, High Holborn, London.—*Seed Catalogue, 1889 (Illustrated with Coloured Plates).*

H. & G. Sharpe, Wisbech.—*List of Seed Potatoes.*

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (Horace).—If you write to Mr. B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, London, N., we think he will be able to supply what you require. (D. S.).—The sixth edition of "Mushrooms for the Million" is in the press.

White Sport from Chrysanthemum La Nympe (J. M.).—We should think the variety will prove a useful one for decorative purposes, either grown for cutting or as a specimen plant, but the bloom does not appear to possess sufficient substance for exhibition.

Violets in Winter (T. S.).—Plant rooted runners or suckers in April or early in May, in good rich soil a foot apart every way, water well after planting, and in dry weather, keeping clear of runners and weeds; and at the close of September move to frames placed in a dry sheltered situation, and sunny, planting so as to be not more than 9 inches from the glass. The lights to be kept off day and night until frost, and then kept on the frames without air when frost prevails, but whenever the weather is mild air to be given day and night in proportion to the coldness or mildness of the weather. Remove all decaying leaves as they appear, and do not plant closer than 9 inches apart.

Peach Trees for Forcing (Anacrus).—The shoots you send are very weak and the buds advanced, but growth may be retarded till the time you name. A degree or two of frost would do no harm, and no firing should be resorted to except for first excluding frost, ventilating free should the weather be mild. The faulty kernels are either due to defective fertilisation or the lack of calcareous matter in the soil, if not both. If the wood sent is a fair sample, we should not expect the trees to continue bearing satisfactorily much longer unless better root action is encouraged in fresh and good soil. You will find much good information on the management of Peach trees and forcing in the "Work for the Week" columns of the present issue. There is no seal on the shoots sent, and any on the older wood can be destroyed with Gishurst compound or a softsoap solution with a little petroleum added, applying with a brush.

Forcing Asparagus and Potatoes in Frames (C. W. W.).—You will need to make up a bed of well-sweetened dung and leaves about 3 feet high, well beaten down, and putting on the frame in about a week, when the heat will have risen; and when it declines to a temperature of 75° it may have soil put on 6 inches thick, and when this is quite warmed through put in the Asparagus plants quite closely together, with soil carefully placed about the roots, and between each layer of plants, the crowns not covered deeper than 2 inches, and the distance from the glass should be 12 inches. The temperature of the bed should not be allowed to decline below 65°, but be kept up by linings, and protected with mats over the lights, so as to maintain in the frame a temperature of 55° to 65°. In about a fortnight the shoots of the Asparagus will be fit to eat. The mats in mild weather after the shoots are 4 inches long should be removed by day, so as to give colour and flavour. The Potatoes to be planted in the bed in rows 15 inches apart, and 1 foot apart in the rows, and 4 inches deep, employing sets previously sprouted an inch long. It is well if the sets are not planted until the heat at 4 inches deep has declined to 70°, and it should be kept up to 65° by linings, protecting from frost by mats over the lights, giving air after the haulm appears whenever the weather is mild. The main point to be aimed at is a steady growth. Avoid overheating.

Raising Plants from Seed for Rockwork (M. R. S.).—Alyssum saxatile compactum, Antennaria dioica minor, Arabis alpina, Aubrietia græca, A. purpurea grandiflora, Campanula carpatia, C. carpatia alba, Dianthus neglectus, Erinus alpinus, Saxifraga aizoon minor, S. Cymbalaria, S. longifolia, Silene caucasica, S. Schafta, and Veronica saxatilis and V. prostrata are suitable. Seed should be sown in April in pots or pans well drained, and filled with a compost of turfy loam and sandy peat in equal proportions, with a fourth each of leaf soil and silver sand, the compost sifted, and the surface of the pots or pans made very fine and smooth, and well watered, standing for a few hours, then water again, and when the water has soaked in scatter the seed evenly over the

surface and just cover it with very fine soil. The pots or pans should be placed in a sheltered position, and so that the sun does not fall upon them from 8 A.M. to 5 P.M., or shade from the sun for that period, the main point being to keep moist without having to resort to frequent waterings. When the young plants are large enough prick them out about an inch apart in pans prepared as for the seedlings, treating them similarly, and before they become crowded plant in the rockwork, shading until established. Seeds of rock plants are not in given kinds always procurable, hence we advise you to procure a collection of half a dozen or a dozen kinds as you may wish, stipulating for good free-growing hardy kinds.

Shrubs and Plants for Shaded Border (S. S.).—The best of all is the *Aucuba japonica*, then Tree Box, Butcher's Broom, Evergreen Privet, common Laurel, common Holly, and English Yew, with St. John's Wort and Periwinkle as undergrowth, also Ivy. If the ground is not very much occupied with roots, and is dry, *Rhododendron ponticum* succeeds fairly, and in some instances we have found *Laurustinus* do well. Plants for the border may be *Alyssum saxatile compactum*, *Anemone apennina*, *A. japonica*, *A. nemorosa flore-pleno*, *Arabis alba* and var. *variegata*, *Aubrietia deltoidea grandiflora*, *Caltha palustris flore-pleno*, *Campanula aggregata*, *C. rapunculoides*, *Convallaria polygotatum*, *C. majalis* var., *Delphinium Belladonna*, *Funkia undulata variegata*, *Helleborus niger*, *Muscari amethystina*, *Hypericum calycinum*, *Iris germanica*, *Myosotis dissitiflora*, *Nepeta Mussini*, *Paeonia albiflora* var., *P. officinalis* var., *Primula acaulis* var., *Pulmonaria angustifolia*, *P. officinalis*, *Spiraea filipendula plena*, *S. japonica*, *S. palmata*, *Diclytra spectabilis*, *Trollius europaeus*, *T. napellifolius*, *Viola cucullata*, and Violets in variety. The border, we presume, is not overhung, but only shaded by the trees. Ferns that would do are *Osmunda regalis* well supplied with moisture, *Lastrea Filix-mas*, *L. dilatata*, and vars. of both; *cristata*; *Athyrium Filix-femina* in vars., *Onoclea sensibilis*, *Polypodium vulgare*, *Polystichum angulare* vars., *P. aculeatum*, *Struthiopteris germanica*, and *Scolopendrium vulgare* vars.

Calceolarias Failing (E. Evans).—We entirely disagree with you as to the disease being occasioned by inserting the cuttings in cold frames—an opinion that has been expressed before. We remember the time when *Calceolaria* cuttings were invariably inserted in pans, struck, and wintered in an airy greenhouse. There was then the *Calceolaria* disease, and it has only shown itself more of late years from the greater number grown. It is many years since Mr. Fish first propounded the practice of wintering *Calceolarias* in cold frames. It is a practice we have followed with the best results. Our method is very simple. We make ready a place in a sheltered open situation, putting a few inches of lime riddlings on the ground and ram quite hard. Worms do not come through that, and we then set the frames on bricks laid flat. Coarse gravel is then placed all over the bottom to the depth of 3 inches, and next an inch or two of coarse compost, and 3 or 4 inches of finer, which consists of two-thirds loam and one-third leaf mould, and then from 1½ to 2 inches of rather coarse sand. The cuttings are inserted 1½ inch apart every way, a good watering being given. Ashes are placed against the sides of the frame all round, plenty of air is given in mild winter, and protection is afforded from frost. Early in March if the weather is not frosty the points of the cuttings are pinched out, and in the beginning of April we make trenches as for Celery, only 4 feet wide, with 3-feet alleys between them, and put in plenty of well-decayed manure and leaf mould, mixing these materials well with the soil. The plants are planted in rows across the beds, 6 inches apart from row to row, and 8 inches from plant to plant. A good watering is applied, and then water is given sparingly for a time until the plants are growing freely, when abundance is afforded. They are protected from frost by old lights or mats resting on spars placed across the trenches. The first week in May the plants are again stopped, and we have dwarf bushy plants that rarely fail to flourish in deep rich soil.

Hollies (E. Dawson).—The varieties best adapted for different forms are prepared both as pyramids, bushes, standards, and weepers. You will have no difficulty in procuring what you want from a nursery where evergreens are well grown. Still, the following remarks from a practical cultivator may perhaps be suggestive:—Pyramids.—It is the natural habit of most varieties of Holly to form a pyramidal form, in which character they are very pleasing as single specimens; but a little assistance is sometimes requisite in training the leader upright and cutting in the other portions to secure the desired shape. With a very little manipulation of this kind splendid trees may be had from 20 to 25 feet in height of all the robust growing kinds. Perhaps the variety known as *Hodginsi* is one of the best and most rapid growers for this purpose. It has also bold and handsome foliage of deep glossy green 3 to 4 inches in length, deeply but tolerably regularly spined. The Golden, Bronze, and Silver Queens, Gold and Silver Milkmaids, *Angustifolium flavum* (yellow berried), *Doddintonense*, *Handsworthianum*, *laurifolium*, *Madeiriense*, and *ovata* are all suited for making good specimens. Bush specimens will include all varieties that are of a dwarf dense habit. The most notable of all Hollies for this purpose is *Waterer's*; plants of this splendid hardy and compact rich golden Holly generally grow into dwarf dense bushes without any assistance whatever; shrubs not more than 4 to 6 feet in height will often measure 13 and 14 feet in circumference. The leaves are medium-sized, oblong, smooth, and almost spineless, with a marginal band of deep golden yellow—altogether a very distinct variety, and ought to be in the most limited collections. *Ferox* (the Hedgehog Holly), and its varieties

foliis argenteis and *aureis* are also very suitable for bush specimens. Weepers.—These are worked on clear stems of various heights. Some few varieties possess a natural weeping habit, the branches in a few years bending down to the ground and make most elegant specimens. A weeping variety of the common green form is very robust in growth and handsome when worked after this manner. *Perry's Weeping* is beautifully variegated, and is altogether a most attractive variety, as is also the new *Golden Weeping*. Standards.—Compact, round, well-balanced heads on clean straight stems from 3 to 6 feet in height can be easily obtained of nearly every variety in cultivation; but the Golden and Silver Queen varieties, as well as some of the choice green-foliaged varieties, are most generally grown in this form. The heads are regularly and methodically trimmed in, and specimens are produced well adapted for a winter garden of evergreens.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*A Reader*).—1, *Sericographis Ghiesbreghtiana*; 2 and 3, insufficient without flowers; 4, *Justicia flavicomis*; 5, *Cyperus alternifolius*; 6, *Imantophyllum miniatum*. (*J. M.*).—*Maxillaria picta*. (*J. L. R.*).—Specimens too imperfect, except 4, which is *Coccoloba platyclada*. (*M. S. T.*).—A good variety of *Cypripedium insigne*, very little inferior to *Maulei*. (*W. M. M.*).—The flower differs slightly from *Mdile*. *Mélanie Fabre* as ordinarily seen, but we believe it is that variety.

COVENT GARDEN MARKET.—DECEMBER 19TH.

NO alteration. All classes of goods well supplied.

SHEEP MANAGEMENT.

In the preparation of the lambing fold care is taken to select as dry and sheltered a place as can be had. It is not often that farmers are so fortunate as to have a lambing yard enclosed by a wall or boarded fence with due provision of shedding and cribs, but there are many homesteads where a yard might be spared for the purpose, and it is always advisable, for the flock is then more immediately under the master's eye, and a lot of contrivances for shelter can be put up or made better in a yard than elsewhere. Given only an enclosure we can easily contrive snug cribs with hurdles thatched with straw, which answer admirably for the roofs as well as the sides. There must be plenty of single cribs, and three or four little yards, each having its shed or crib large enough to take in six or a dozen ewes with their lambs. Ewes that have suffered from straining or with delicate lambs require keeping apart for a few days in a sort of hospital yard for special attention and nourishment. Last lambing season we mentioned having seen a line of waggons laden with straw across the middle of a lambing yard with thatched hurdles placed along on one side against the waggon wheels, and thus affording shelter for sheep and lambs turned out in the yard. The lambing yard or fold should be near some good pasture for ewes before lambing and for ewes with lambs to go out upon as the lambs become strong enough. But the lambs must never be subjected to exposure to cold cutting wind even by day, and for the first few weeks they should always be taken into the folds by night. We have known dozens of lambs to be lost simply through exposure, which might easily be avoided, and we know no more lamentable sight in farming than that of a lot of starveling ewes with weak lambs turn out upon bare open pasture without shelter of any sort. Such an example of mismanagement may appear strained and far-fetched, but we saw it last season greatly to our regret.

There is nothing more interesting or pleasant to behold in farming than a well arranged lambing fold. On every hand we have evidence of energetic care and thoughtful attention to every want of the sheep. A fine fall of lambs is the crown of a year of careful management, and a little boastfulness or conceit on the part of the shepherd may well be pardoned, for very much depends upon his care of the sheep, not simply during the lambing, but always. As the ewes become heavy with lamb they are kept as quiet as possible, any sudden change or alarm causing abortion, and sometimes the loss of both ewe and lamb. Last lambing season the most valuable flock in our neighbourhood sustained serious harm by being driven out of the fold at night by some poachers' dogs—a sort of mongrel lurcher—of powerful build and great speed, and therefore able to do much harm to the sheep. We mention this to put beginners on the alert, the knowledge gained of such cases of mischief being part of dear bought experience.

During the lambing notice must be taken of all bad cases, and all ewes marked for drafting and fattening later on that prove unfit for breeding. Have at hand some carbolic oil and a syringe for use in cases of severe straining, first washing the vagina with warm water, and one or two applications of the oil slightly warm usually give instant relief and saves the ewe. Ewes suffering much from straining should not be retained for another season, nor should any having protrusion of the uterus. This may be cured temporarily, but the ewe is subsequently unfit for breeding. Far better is it to withdraw and fatten even doubtful animals than to run the risk of loss next season. This is one of the reasons we have for preference to home-bred ewes. We know them from infancy, and save only the robust for the

ewe flock, but purchased ewes may or may not be safe; the buyer has to take his chance of that, and there are generally some losses.

Foot rot in a ewe flock is a thing we much deplore. It invariably becomes worse during the lambing, for it is unsafe to cast the pregnant ewes to trim and dress the feet, and it is sad work when a ewe heavy with lamb becomes very lame. It makes a hurtful tax upon the frame, and the lambs soon become lame too, for the disease is very contagious. There is no real cure for it. We may, and do heal bad feet by paring, washing, and dressing with Gell's ointment, but if once a flock gets the taint of foot rot it is always liable to an outbreak. The feet of any lame ewes have attention in a day or two after the lambing, all over-grown or broken parts of hoof being pared off carefully with a sharp knife, the foot well washed with tepid water, and the ointment well rubbed into the sore part. Very bad cases are poulticed with linseed meal, or bandaged with ointment or rags to keep the sore part from contact with the ground.

WORK ON THE HOME FARM.

Till within the last few days the weather was so mild that grass continued growing freely, and if only snow keeps off we shall have plenty for the ewes for the next month or two. This abundance of grass proves so nourishing that we did not begin using corn so early as usual for the ewes, but they must now have crushed Oats regularly. We have been able to keep the hoggets in Turnip folds with very little change, and they are in thriving condition. Turnips are so abundant this winter that farmers are offering them free to flockmasters if only they will send sheep to consume them on the land. This is not as it ought to be. The season has been most favourable to the development of a full crop of roots, yet farmers of slender means have no sheep, nor can they afford to purchase them to consume a crop for which they pay so dear. Surely this is one more lesson of the folly of farming with insufficient capital. Far better, say we, to farm a little and farm well. The risk would be less, the profit more assured, and farmers again be prosperous. We miss no chance of urging this upon general attention, and mention of it is not out of place even in our farmwork note.

Sales of farm produce still take up much time. We have this week realised £90 for pigs, and find our plan of turning inferior Barley into pork answers very well. We avoid all waste, and by using only home grown food there are no corn bills to meet, and the margin of profit is very satisfactory. We can mark no improvement in the corn trade. Our sales for the week amount to 250 quarters, the highest price for Barley being 28s., and for Wheat 36s. This is a fine sample of white Wheat, very fine, dry, and hard, yet the price falls from below that of the best foreign Wheat, the quotations for which varied as high as 45s. per quarter last Monday. If only we could obtain 40s. we should rest content, but it is only for old home-grown Wheat that such prices are given, and it is only a favoured few who can afford to wait for them. As Wheat is threshed the straw is carefully stacked and thatched, most of it being intended for sale eventually, only enough being kept for thatching hay and corn stacks next season. There is a brisk demand for straw, and we have no difficulty in selling all we have at fair prices.

OUR LETTER BOX.

Cabbage-slicing Implement (C. L. C.).—A Bullock Turnip cutter would answer your purpose best. We have never seen a Cabbage cutting machine, nor do we think such an implement at all necessary, sheep as well as cattle being able to consume the Cabbages perfectly well without any cutting.

REMARKS.

9th.—Fair and generally bright day.
10th.—Very cold dense fog early, gradually cleared, and bright sun from 11.30.
11th.—Dense fog, clearing gradually all day, fine evening and night.
12th.—Slight fog early, fine bright day.
13th.—Fine and generally bright.
14th.—Fog all day.
15th.—Fog all day.
A cold, foggy, and rainless week. Temperature about 11° below that of the preceding week, and nearly 6° below the average.—G. J. SYMONS.

THE CLOSING YEAR.

BEFORE these notes see the light in the pages of the Journal Christmas will have come and gone, and the shadows of the year will be casting their fading forms around us, the Journal itself will have finished another year of its long and successful course, and many will be looking forward hopefully to the future. Christmas is the joy of the young: to the old, perhaps, the saddest period of the year. We recall insensibly the Christmases we have passed, the Christmases of joyous and innocent childhood, and the happy ones of a later period when our home was unbroken. But now each year has brought with it the severing of many ties! Dear ones are scattered over Earth's wide surface, and we ourselves are waiting for the time when our place will be empty. But I do not want to cast a shadow over our retrospect, although I rather think it would be in accordance with the character of the year, so far as we regard it in a horticultural aspect, for rarely, I suppose, have gardeners experienced a more gloomy and disappointing time. Absence of sunlight puts all things out of course. Everything was three weeks or a month behindhand; fruits and vegetables alike lacked flavour, and then when we were looking for a fine autumn there came to us, in many places, on October 3rd, a "chilling frost," which crippled many of our flowers, turned our Dahlias black, crippled our Zinnias, stripped our Fig trees bare, and generally made a wreck of everything. Had it not been for this one night our gardens would have been indeed a joy to us, as my friend Mr. Ewbank's seems to have been to him on the favoured Island, where, as I have been told, it does not matter whether you put in a plant bottom upwards, for it is sure to grow and assert itself. Herbaceous plants stood it best, but even with many of them it was a race for life.

I think the first thoughts of a writer at the present time will be for the medium through which those thoughts have been made known, and I think that we are ready thankfully to greet our revered "Boss" that he has so successfully steered his vessel through another year. He has enlisted new recruits, and with the able assistance that he has, I think we may regard the onward progress of the Journal as well assured.

Turning from this our thoughts recur to the great central heart of horticulture in England, the Royal Horticultural Society; and here again we have cause for much thankfulness. Although it has not been able to shake off that old man of the mountain, "the Charter," yet by a judicious alteration of bye-laws much of its burden has been removed, and much has been done to revive an interest in it and make it what it ought to be, the representative of horticulture in England. It is unfortunate in the place in which it holds its fortnightly meetings, and Chiswick is not and never can be what it was. We all think the Superintendent is the right man in the right place, but it is more and more surrounded by houses, yet as a representative garden it is valuable. We have now a working Council, an admirable Hon. Secretary, and we can look upon its proceedings with hopefulness and not with suspicion, and we sigh and think if such had been its character some five and twenty years ago what a different position it would have been in now. There is no use in crying over spilt milk, and so we must all not only wish it well but work for it.

I do not think that the past year has brought before us anything very remarkable in the floral world. The love (or shall we call it the rage) for Orchids still continues, and especially has it developed itself in the genus *Cypripedium*. This is to my mind (it may be

ignorance) a very strange plant affection. Neither in form nor beauty of colouring can it as a class compare with many others—with the soft and lovely colours of the *Cattleyas* and *Laelias*, with the varied and graceful forms of the *Odontoglossums* or *Dendrobiums*. And yet what remarkable prices have been given for these queer-shaped flowers! They have, I suppose, a special charm for orchidists; but as one of the outside mob I think it is one of the last that I should be enslaved by. Nor have we in the other departments of horticulture seen anything very remarkable. It may be, as we say, there's nothing in the papers, because we are expecting some great and startling news to greet us, so we want in these sensational days something very extra to excite our satiated appetites. In florists' flowers it has been a disappointing season; everything was late, and this affected our exhibitions. Auriculas made but an indifferent figure at the Drill Hall, while Carnations and Picotees were lamentably deficient. Roses everywhere middling, deficient in number and lacking in quality; Dahlias late and not up to the mark; Gladiolus very late, many of them not flowering at all; and even of the hardy *Chrysanthemum* many complaints of damping off and being very late.

As to fruit and vegetables, as I have said, they have lacked flavour, and the absurd desire to get big things is, I think, taking the flavour out of some of our most cherished vegetables. Peas, for instance. I do not care to have Peas as big as a Broad Bean and nearly as mealy. The size is dearly purchased at the expense of quality, and we shall have to hark back to the Peas of twenty years ago if growers are not more careful on this point. Then, again, Brussels Sprouts: we have them now, the delight of gardeners, who, as a rule, adore size, whose Deity is rather Juno than Venus, but strong in comparison with what one used to grow as "imported Sprouts," and to which we shall have, perhaps, to return. What is the use of a Broccoli that will fill a bushel basket, or a Potato as large as a cannon ball? The same thing runs all through. I see the flavour of a Tomato taken little into account, although it is a very essential point when they are used in one of the best forms as a salad. In mentioning vegetables one must say a word about the new "*Crosnes du Japon*," or *Stachys*, of which much has been said. My own experience of it is not very favourable, but tastes differ, and perhaps when we learn a little better how it may be cooked we may like it more.

A great impetus has been given to fruit-growing, and many schemes have been started to favour it. By all means let gentlemen and farmers increase their fruit-growing, but it should be remembered they must wait eight or ten years before they can make much profit. That some better way of disposing of the fruit is needful there can be, I think, no denial. What think you of 1s. 6d. for a half sieve of good Doyenné du Comice and Beurré Clairgeau Pears? Is not that fruit-growing with a profit with a vengeance? and yet that is what I was assured by a friend the other day, was all that he obtained in Covent Garden. There is apparently a "fruit-ring" which requires to be broken. There has been nothing very startling in novelties. Noble is a good addition to our early Strawberries, Emile d'Heyst to our Pears, and Bismarck, Beauty of Bath, and Lady Sadeley to our Apples. In Grapes there is nothing new to record, and Black Hamburgh and Muscat of Alexandria still hold their pre-eminence as the two best Grapes for general cultivation.

We have not to record any great losses amongst the personnel of the horticultural world. Some have, of course, been taken away, but they occupied no very prominent position. We were at one time in great suspense about the *doyen* of horticulture, our amiable friend Mr. John Lee. For some time we were daily expecting to hear of his departure, but his vigorous constitution although at his advanced age (eighty-two), he has recovered and when I saw him a week ago he was the same bright and cheery old gentleman that he was before his illness. May he be long spared to us!

Each season must bring with it its lessons, but the danger is that in our variable climate one season is so unlike another that we must not suppose it is always to be the same as that which we have suffered from. Could anything be more opposite than the seasons of 1887 and 1888—one, the perfection of a summer, the other without any summer worth the name? In fact an English gardener must be armed at all points and be cautious. Already I see that persons are calculating on a late season next year because we have had a late one this year, whereas it may be an early one. We have a dry season, and we get all sorts of warning about the folly of not storing our water; we have a wet one, and then we are told how foolish it is not to devise means of getting rid of our superfluous water. Do not run into extremes; the middle course is the safest.

And now, my brothers and sisters in the craft, a word of encouragement. "I have been young and now am old." I can look on upwards of fifty years of gardening, and can truly say that it has been to me a source of joy and happiness. A large portion of my life was an arduous and weary one, but I can say that, whether in the midst of all the cares and worries of a large town parish, or in the quiet moments of a rural one, I have ever found my love of flowers helpful. I love them for their own sakes, and they have returned my affection. I can say, too, that they have brought to me many friends and but few enemies (I believe that the man who has none is a poor jellyfish sort of a man who has shirked his duties and responsibilities); and now, as the evening of life is closing round me, I can wish my readers no better wish than that they, too, may find in their gardens the solace and the pleasure that I have done; and so, in this, the last issue of a year's Journal, in which I have often spoken to them, I wish them one and all,

A HAPPY NEW YEAR.

—D., Deal.

COVENT GARDEN AT CHRISTMAS TIME.

At all seasons of the year a visitor who is interested in the horticultural products of this country can spend a profitable half hour in Covent Garden Market, especially if he select the early hours of a market morning for his visit. But at particular periods of the year, whenever the British public are preparing for a general festival, and cultivators are making special efforts to meet the demands for abundance of flowers, fruit, and vegetables, Covent Garden Market can be seen at its best and its astonishing resources realised. For general supplies, no time of the year equals Christmas. In the spring months there is, of course, a greater abundance of flowers, and during the Strawberry season there is a corresponding bustle in the fruit market, but at this time of year concentration of work and supplies is more evident in all departments together than at any other time. Salesmen, shopkeepers, and porters are busily employed in disposing of the produce which arrives in such large quantities, the frequent auction sales are attended by crowds of eager purchasers, and the whole aspect of the market is one of earnest hurried business. A brief glance at the respective departments will give some idea of what is provided for metropolitan celebrators of the Christmas festival.

FLOWERS.

The chief demand is apparently for white flowers, at least these constitute a large proportion of the supplies, Chrysanthemums, Lilies of the Valley, Camellias, Eucharis, and Roman Hyacinths, with the stately spathes of Richardias being first favourites amongst these. But in addition there is abundance of white Azaleas, Bouvardias (these also furnishing coloured varieties valuable for wreaths, sprays, and buttonholes), Cyclamens, Lapagerias, Carnations, and French Lilac, Paper White Narciss, Roses, Tuberoses, Gardenias, and Stephanotis. Several of these, besides the Bouvardias of course, also afford coloured flowers, as Cyclamens, Lapagerias, Narciss, and Roses, but the principal rich colours are afforded by the Zonal Pelargoniums, the Poinsettia bracts, and the brilliant wreath-like branches of Euphorbia jacquiniæflora. More delicate shades are supplied by Primroses, Mignonette, and Marguerites, while the indispensable Violets, though numerous, seem to be in unfailing demand. From this list Christmas Roses (Hellebores) must not be omitted, as they are especially appreciated at this season, and they make charming wreaths, one we saw recently consisting of bronzy Ivy leaves and Christmas Roses alone having a

most elegant appearance, far superior to those overloaded with Richardias or even Camellias.

The plants in the market at this time of year consist mainly of small evergreens in pots, with the ordinary foliage plants employed for decorative purposes, such as Palms, Dracaenas, and Ferns, but amongst flowering plants the winter-flowering Heaths are conspicuous, Erica hyemalis and E. gracilis being sent in large numbers. Forced bulbs, like Roman Hyacinths, are plentiful, but Lilies of the Valley in pots are not supplied very largely so early as this. Poinsettias, Marguerites, Pelargoniums, Primulas, Solanums, Cyclamens, Chrysanthemums, and Begonias are sent in by many growers, Cyclamens being perhaps the most numerous.

FRUIT.

During the whole of last week the market has appeared to be simply glutted every day with fruits; huge piles of boxes, barrels, and baskets filled every available portion of space, and it is astonishing where such quantities could be disposed of. Apples and Oranges are the two great features of the Christmas market, and the supply this year seemed to be greater than ever. It has recently been noted that the supply of American Apples is larger than usual, nearly twice as many (half a million barrels) having been already shipped to Europe as in the same months last year. In the Floral Hall at Covent Garden many thousands have been sold by auction within the past week, one salesman alone having disposed of 4000 barrels in a morning's sale. These are mainly Newtown Pippins, which command the highest prices, and the fruits take their places in the best fruiterers' windows, the richly coloured Baldwins, and King of Tompkins County, which some of the shopkeepers abbreviate to "King Tompkins." A few choice consignments of English Apples are seen, but these are very much in the minority.

As an ornamental Apple, the pretty little Api, or Lady Apple, tastefully wrapped in coloured tissue paper and displayed in neat boxes, is very notable, and few, probably, of those who admire it, have any idea of the history attached to it. A full and learned account is given in Dr. Hogg's "Fruit Manual," but the chief points are that it is of great antiquity, and has been said to have been introduced to Rome from Peloponesus by Appius Claudius, though others assert it was first found as a wildling in the forest of Api in Brittany. It was not known in this country until the end of the seventeenth century, and is now extensively grown in the United States.

Pears do not call for special mention. Grapes include both English and foreign produce, the former running up to 4s. 6d. per lb., quite a small price compared with what used to be paid for good Grapes at Christmas. Oranges are supplied in thousands of cases, from the huge Jaffa variety to the miniature and delicately aromatic Tangierine, which, in silver paper and ornamental boxes, makes a companion for the Lady Apples already noted. Pine Apples are seen in all grades and qualities, from those which make their subsequent appearance on costermongers' barrows to handsome fruits of exhibition size, which adorn the windows of such fruiterers as Messrs. Webber & Solomon in the Central Row. Of other tropical fruits the Prickly Pears, Mangoes from Madeira, Custard Apples, and Lychees are the principal, but they are only sold in relatively small quantities as curiosities, or for the tables of those who have been familiar with them in other lands.

Nuts are also an important commodity in Covent Garden at Christmas, bulky bags and capacious baskets being filled to overflowing with small nuts, Brazils, Chestnuts, Almonds, Cocoa Nuts, and Walnuts; while of what may be termed the curiosities there are Sapucaias, something like Brazils, and the Butter-nut (Caryocar nuciferum), not often seen in London markets.

The indispensable Christmas accessories, such as Mistletoe, Holly, and miscellaneous evergreens for decorative purposes, are supplied as usual in large quantities, the crates of Mistletoe arriving by waggonloads. It is evident that, great as is the annual demand for this plant, there is no falling off in the supply.—VISITOR.

STEPHANOTIS FLORIBUNDA.

DURING the past few years we have heard considerably less about shy or non-flowering varieties of this plant. I am of opinion that there have never been substantial reasons for such opinions, and the fault has been with the cultivator and not with the plant. I do not mean to infer that there are not varieties of different merit. It is just possible that improved forms may be in existence by raising seedlings and careful selection. Two examples have come under my own observation, and the only noticeable difference that I could discern was in the shape of the foliage, the difference being so slight that it was not seen by a casual glance

at the two plants. One was considered a free-flowering variety and the other the shy-flowering sort. The latter was raised from a cutting from a plant that was condemned on this account and thrown away, and which was slightly rounder at the extremity of the leaves than the other. As the plants increased in size it became necessary to select one or the other. The choice fell on the largest plant, which was the shy-flowering one, although it had not displayed any disposition to flower freely up to this stage. But we have had no occasion to regret the choice, for during the past two years, although the plant has grown luxuriantly, it has also flowered profusely. Some of the short stubby growths have been regular bouquets of bloom, while the long strong growths (some of them 2 inches in circumference at the base) have yielded large trusses at every joint.

In many gardens this plant is grown under conditions that are not favourable to flowering it even moderately well. The stove proper is no place for the *Stephanotis*, and under ordinary stove treatment I should be surprised if it did flower satisfactorily. The conditions of an ordinary plant stove is too warm and too moist for it, often too shaded, and in addition the plant is deprived under these conditions of a complete season of rest that is of the utmost importance if flowers are to be had in abundance. The heat and moisture of an ordinary stove are certainly favourable to rapid, even luxuriant, growth. Anyone anxious to produce large plants quickly could not do better than push them on in brisk heat and in a moist atmosphere, but when they want flowers the treatment must be altered, or disappointment is certain to follow.

I have said plants that fail to flower satisfactorily are often overshadowed, and this may arise, not only from the application of shading to the roof, but by training the shoots of the plant too thickly together. This course is objectionable by affording too much shade to the young growths, and it prevents the thorough ripening of the wood after flowering by the exclusion of light and air. This method of training provides one of the best harbours for mealy bug that can possibly be had. To flower the plant profusely it should be freely exposed to the sun. This insures the solidity of the young wood sufficient to flower well and thorough ripening afterwards. Training, on the principles indicated, may be followed to prevent the shoots twining together and thus becoming unmanageable. The best of all methods of training large plants grown under the roof is to draw the shoots as they grow from the roof and allow them to hang from the plant in a natural manner. Although the shoots grow several yards in length on this principle, they appear to flower with greater freedom than if trained thinly on strings close under the roof, which is the next best method of training the growths of vigorous plants. If the shoots are drawn downwards they are kept in order with very little trouble, and insects are easily kept down by being able to syringe every portion of the plant. Drawing the shoots down so that they hang naturally is advised after the plant has filled the space allotted to it, or is sufficiently full of wood at any position under the roof. If the object is to fill space, then all the leading growths should be trained under the roof. This method allows of securing double the wood that would be the case if the young shoots had to be trained in that position as well. This means double the flowers, or nearly so. By this mode of culture the earliest shoots that have flowered can be cut close back. They invariably, in a good season, produce others that will flower freely. At any rate the wood can be thinned without much trouble when cleaning and pruning time arrives, and that left is needed for training under the roof. When once the roof is well furnished the whole of the shoots can be pruned close back, leaving two or three pair of leaves only on the current season's wood. The cutting away of large quantities of wood at one time should not be practised; it should be done gradually to avoid a check to the roots, and thus causing quantities of young fibry roots to die.

Sometimes the stove is too warm and too moist for this plant. The conditions generally maintained in such structures encourage soft wood at the expense of flowers. If blooms are required early the plant may with advantage be started in a brisk moist temperature, but as soon as the growths are 9 inches or 1 foot in length gradually lower the temperature by using less fire heat at night and by admitting air during the day. This means a dry atmosphere and firm wood. From the end of May this year we discontinued the use of fire heat. Air was admitted liberally during the day, and the house closed moderately early during the early part of the season. Since then the ventilators only have been closed at night; during the day the structure has been aired the same as a greenhouse. During October and until the plant is started again into growth the night temperature will be 50°; in case of severe weather we shall allow it to fall to 45° by morning. The atmosphere for some time has been dry, and the plant on the dry side at its roots. Under these conditions ripened wood of the best quality and a complete rest is insured.

By following this or similar treatment, and growing the plant in fibry loam and one-seventh of manure, with charcoal and sand added, the supposed shy-flowering varieties would prove themselves profuse enough to satisfy all.—WM. BARDNEY.

CHRISTMAS VEGETABLES.

ABOUT this time last year, when complimented on the quality of our Pine Apples and the excellence of our forced Asparagus, we took it as a good opportunity to remark that our glass structures were neither so modern nor numerous as we would like them. The reply was, "Perhaps not, but we always have plenty." To merit this remark has been our ambition for many years, and it represents an accomplishment which every cultivator in the country should strive to acquire; but more especially at Christmas, when produce is expensive in the market and much appreciated on the table. If ample forcing appliances are provided Asparagus, Seakale, and Rhubarb should be forthcoming in quantity at Christmas, and where no special constructions are supplied for the purpose efforts must be made to work them in by contrivances.

To have superior forced vegetables now, apart altogether from forcing appliances, it is absolutely necessary that the roots be well grown. Weak Asparagus roots, spindly Seakale thongs, and exhausted Rhubarb clumps will never yield strong, juicy, and abundant produce. It is therefore the duty of all who intend forcing these at Christmas to supply themselves with suitable roots, and to do this several years are required; but when forcing is converted into a system and provision is annually made to meet the demands good roots will never be wanting. Asparagus, Seakale, and Rhubarb are the main kitchen garden roots for forcing; each of them gives the highest satisfaction on the table at this time, and the more detailed means of growing them have often been given in these pages. Next to these, as an artificially grown commodity, come Mushrooms. They form a valuable breakfast as well as a dinner or supper dish, and plenty of Mushrooms, especially when open air vegetables are scarce, are most valued. In Mushroom growing, and indeed in all else that has to be in for Christmas, a great deal of forethought is required, and with a due amount of this properly applied there need be little anxiety; failure will be the exception.

But it is not in forcing roots alone that forethought is needed. We all know that herbs are luxuriant in summer and in greater demand at Christmas than any other time; but their abundance four or five months ago will do nothing to supply the demand now unless quantities were cut, dried, and stored in the season of plenty. This may appear a small matter, but we have known many good gardeners considerably worried over this little omission. This is no season for raising and hurrying in any vegetables in the open air. The majority of them must have been planted some months previously. These include Brussels Sprouts, Savoys, Leeks, Broccoli and Spinach. Brussels Sprouts are quite in season at Christmas. At that time they may be regarded as the choicest of all open air greens. Although the past season was not in their favour they have "buttoned" well, but they have hardly gained their usual height. Savoys are much coarser, yet useful. Broccoli are not always plentiful at this time of year, even where plenty of plants are grown, as their "heading" depends very much on the weather. Frost is much against their forming, but it does not kill the plants and only retards them. Spinach should be almost fully grown before now, as it does not make much progress at this season. Parsley is always in great demand. Full grown plants are the most useful. Frost shrivels it considerably, and it may be necessary to protect some with hoops and mats. Parsnips may be left in the ground and dug as required, so long as the ground does not become frost-bound, and previous to this a quantity should be lifted and stored for use during the time the frost lasts. The same remarks apply to Salsafy. Roots, and bulbs, including Carrots, Beet, Onions and Potatoes, should be stored early in winter for Christmas use. Onions are important, and a good supply of them must be forthcoming. Until now these roots have not kept so well as they have often done, and as they will all be required for a long time they must be examined and all defaulting specimens removed. Mustard and Cress are great helps in salads, but they are so easily raised in quantity that little need be said about them.—A KITCHEN GARDENER.

GARDEN WALKS.

THERE is nothing in a garden, nor connected with it, that affords a greater amount of comfort or gratification than a good walk, for in it "beauty and utility" ought to be strictly united, and, in fact, it cannot justly be called a good one unless it possesses both these qualifications; and for such walks as intersect the kitchen garden utility may be regarded as of paramount importance, for it is reasonable to suppose that the walks in a kitchen

garden have a much greater amount of hard work to do than those in the pleasure ground; their structure must be regulated accordingly—a larger amount of stone being used in their formation. But before engaging on this duty let us take a view of walks in general, and see what alterations the last few years have made in the way these have been brought about.

An examination of one of our ancient highways will easily convince us that our ancestors were more liberal in the materials they used in those days than we are now. The same, in fact, as they were in their buildings, furniture, and other things. Indeed, it does not appear that in the good old golden times there was any lack of materials, and there are few objects now remaining that evince any niggardliness in their construction. Old roads, for instance, contain many cartloads of large stones for their foundation, which the disciples of Mr. McAdam regarded as little short of downright waste. Be this, however, as it may, certain it is that some of their old roads had withstood a deal of wear and tear, and it is questionable if our present economical plan, as we call it, is not accomplished at a certain amount of loss in the stability of the road.

However, as the cartage of stones and other things always forms an important item in the expense of the whole, we may set it down as a paramount duty to make these go as far as possible, which may be accomplished in many ways with better effect than tumbling them into a pool or dirty hole; for it often happens that the formation of roads or walks must take place in wet weather and in muddy places.

The first duty is to well drain the roadway, and, as we suppose our present one to be a garden walk, it will be easy to convey the water into the main drains by which the garden is intersected, supposing it to be so drained, or, if it does not want such draining, still to make sure that the walk be tolerably dry.

My plan in making a new walk in stiff, heavy, clayey ground is to scoop out the interior, so that the centre of it may be some 7 or 8 inches deep or more, while the sides are not more than half that depth; then, along the centre, which is the deepest part, I cut a drain and lay in ordinary drain pipes, filling it up with stones and a coating of stones all over the foundation of the walk, and then a finer sort of stone, and finally the gravel; the advantages of the ground being cut into something like a furrow at the bottom enables the water to run off into the drains and so be carried away. Very broad walks will want two or more of such drains; and I once arranged a considerable width of carriage-front roadway on this principle "of ridge and furrow," which acted admirably, the ground being a tenacious clay and the situation a moist one; but in ordinary garden walks the best roadstone need not be used, for common materials will do; useless lumps of stone or brickbats that may have been in a building will be very useful, especially if there be any of the old mortar adhering, as that is distasteful to worms, which are sad enemies to walks. Clinkers or the refuse of factory fires are equally applicable, or stones of any kind are all alike wanted, the object being to form a sort of bottom through which the water might drain; a harder description of stone may be nearer the top, for the walks of a kitchen garden have often to endure the wheels of barrows and other hand-carriages, so that we must not deny these walks the necessary hardness to bear such heavy loads; at the same time it must be borne in mind that they must present a smooth even surface as well.

Supposing the foundation of the walk to be completed, and that a covering of good hard stones broken pretty small has been laid over that, we will then see what surface material can be had; and in the first place stands gravel, which is, no doubt, the widest-spread material that we have, and which exists, in one shape or other, over most parts of the kingdom; but it is not necessary here to describe the best, as local circumstances usually determine what has to be used. One thing, however, may be said, that the kind which is cleanest in winter or wet weather very often gets loose and feels unpleasant in dry weather in autumn; while that which is somewhat sticky in winter or after rain often becomes very hard and firm in dry weather in summer. These points being extremes, it would be as well to avoid both, and select a gravel containing a part of the good properties of both.

Next to gravel are broken stones, or what are called crushed stones, none being larger than a Walnut. These may be used in like manner to gravel, and some that I have seen are preferable to that article; the best being the kind sometimes had in mining districts where lead and other metals are worked; this I have seen formed into a walk superior to that of any gravel that can be had; but as this can only be had in certain localities we must pass on.

Ashes, or the refuse from some iron-works, or other places where extensive furnaces are at work, form pretty good walks, some being of a sort of copper or bronze colour, and certainly distasteful to weeds and worms, as some of them contain poisonous matter, which makes them a long time proof to weeds. When this can be had it may with advantage be used as a covering to walks;

but it is not applicable everywhere, and if not hard it must not be used too plentifully in kitchen-garden walks, as the stones underneath it must do the work for it.

Many other substances might be used as a covering, but local circumstances often determine them. I will add no more at present, but may say that in hilly walks or those having much descent lime may be used to some advantage. I have used some lime in a pounded state mixed with the gravel when dry and laid on in that state, and after a good watering and beating it gets very hard. This is the principle of concreting; but I have never yet been able to do it so effectually as to prevent the evil effects of summer thunderstorms where the descent is of considerable extent, but this concreting is of great service. Where expense is not an object the best of walks are made of asphalt, and these are perhaps cheap in the end.—J. N.

IVY.

THE Ivies are naturally climbers, and as such they are generally planted. The varieties are often the result of sports, and have a strong tendency to return to the normal state, especially some of the variegated kinds. Nearly all the variations in size of leaf and habit of growth may often be seen in woods, where the common wild Ivy, with small leaves of a grey colour, having shining veins of white, may be met with along with others of larger and greener foliage in every gradation up to the robust Irish Ivy, which, I may remark, is the most useful one we have, and that most generally cultivated. I am not positive that it is the best climber, but its rapid growth, and its property of forming fresh leaves when cut-in, render it suitable to most places where it is subjected to some degree of management.

Even this Ivy presents a difference in its foliage, leaves broadly palmate being met with at one time, while others almost lanceolate or ovate are formed higher up the plant, and the climbing shoot becomes a short, dense, bushy-headed one when it can find nothing to cling to, or where the plant is stunted in its growth, as may be seen where an aged tree is covered with Ivy, and the laterals thrown out can find nowhere else to travel. The Ivies form picturesque, I may almost say grotesque objects, where they cover a curious-headed pollard, and the most symmetrically trained pyramidal or conical Azalea has more than its equal in some large Fir trees that I have seen covered with this plant.

With regard to trimming the Ivy, I by no means agree with some as to the proper time for doing so in the south and more favoured parts of England, though the case may be different in the north, where the plant is less robust. The plan we adopt is to cut-in closely the Ivy covering dwelling-houses in the beginning of August, very often scarcely leaving a leaf, and yet the whole plant is again densely covered with foliage five or six weeks afterwards; and the season being then too far gone, the growth is confined to leaves, which, with us, become firm and established before winter, so as to sustain no injury from frosts. Thus the Ivy looks trim and neat up to the following June, when the summer shoots begin to elongate. It will be seen that there is with this plan a period of fully eight or nine months in which the plant looks as uniform as the wall against which it clings, while the remainder of the time may be divided about equally between the period of the shoots growing in early summer and that of the formation of foliage in the latter part of the season.

Let us see what are the effects of cutting Ivy in March. The formation of fresh foliage or shoots will then take about the same time as in the former case, while the period during which the Ivy forms a close carpet is very short indeed. Shoots of some length are formed, and these, remaining unshortened until the following March, are often in the way when a trim and symmetrical appearance ought to prevail. Observe, I by no means advise the trimming of Ivy in August when there is a danger of the leaves not being produced sufficiently early to withstand the autumn and winter frosts; but when the operation can be performed at that time with safety, let it be done.

As to the propriety of covering a dwelling-house with Ivy, there are various opinions, many contending that appearance is the only recommendation it has; but to trees it is very injurious; many an Oak has been strangled in its embraces, and Pinuses suffer still more. Within a very few yards of where I write, a Spruce Fir upwards of 70 feet high has been for some years struggling for an existence, which is gradually drawing to a close. A few small patches of green on the tips of some of its branches are all the signs of life which it exhibits. The tree may survive one more year, while the mantle of Ivy triumphantly takes possession of the whole of the trunk; the Ivy branches, dense as Box, protrude in all directions, forming an elongated cone of greater symmetry than ever the Spruce did in its best days. The Ivy has not taken possession of any of the dead branches, although many of them

are from 4 to 6 inches in diameter at their base; but the creeper apparently disdains to trust them as supports, and confines itself to the trunk. This support, however, will also have an end, for we have lost several trees, which had become quite denuded of branches, and only presented a beautifully tapering Ivy-covered spire.

The trunk of the tree, when deprived of its vitality, can no longer resist decay, and when it becomes too weak to withstand a high wind, its load brings the whole down. Even Spruce and Larch trees containing from 50 to 100 or more cubic feet of timber are not proof against the elements, and the downfall of the structure is only a matter of time. Sometimes such pillars will be blown down by the root, and sometimes broken off in the middle. One which suffered in the latter way was about 18 inches in diameter at the place where broken, and was not far advanced in decay. Such casualties cannot well be prevented except by bracing up the dead stem, like the mast of a ship, but doing so would mar the effect.—A KENTISH GARDENER.

PRUNING AND CLEANING VINES.

MANY Vines where the vineries are limited are not well cleaned and pruned in winter. The reason of this is that the houses are almost invariably crammed in winter with all kinds of plants. There is no room to turn in them, far less clean and prune the Vines as they ought to be done. "Well," it is said, "we must put it off until the spring, when many of the plants will be cleared out," but in the meantime a little fire heat is applied to expel damp and exclude frost, and this goes on until the Vines are induced to grow, then it is seen they cannot be properly cleaned or pruned. As soon as the leaves have fallen this work might receive attention, and many are now ready for the operation. If the vineries are full of plants these will suffer less through being turned out to another house or shed now than they would do in the months of February or March. There is little use in attempting to clean a vinery thoroughly unless everything is cleared out. When the plants have to be moved back and forward, and from one end to the other, it is difficult to do the work satisfactorily, particularly if insects have to be exterminated. Red spider, thrips, green fly, and mealy bug are the most common, and the latter is, perhaps, the worst of all to clear out.

Pruning, however, should be done before cleaning, and if this operation is neglected the Vines will soon degenerate. The general disposition is to allow too much wood to remain. It is much easier keeping Vines clean, healthy, and fruitful where rods and side shoots are thinned than where they are crowded. If the main rods have become too crowded, now is the time to cut some of them out. Let the most fruitful remain in removing superfluous rods should be the first operation, then go on pruning those that remain. If a Vine has two rods, one old, the other young and vigorous, the latter should be left. If young rods have been recently formed that are strong and capable of bearing a number of good bunches, do not cut them down as was done of old, but let it remain from 6 feet to 10 feet in length. All straggling points should be cut off young rods, and only wood of a fruitful character left, and any little side growth should be removed. Old rods full of spurs from which the young side shoots have been emitted are pruned by cutting in these growths to two or three buds from where they started last spring. Two buds, as a rule, are sufficient to leave, as the longer the growths are left the longer do the spurs become, and this is not desirable. If any spur has produced two shoots, one at the extreme and the other nearer the rod, cut all back to the latter, as short spurs are better than long ones. As pruning is finished attend to the cleaning. The bark on the young rods of this year's growth clings so closely to them that it cannot be removed without injury to the rod, and as no insect can harbour under it, there is no occasion to attempt to remove it, but all rods of more than one year have much loose bark, a favourite hiding place for insects. If mealy bug is there every particle of loose bark must be removed, and to do this it is generally necessary to employ a blunt knife around the spurs. If done with care the wood need not be injured in the slightest.

In washing the Vines add two wineglassfuls of petroleum to every gallon of water, and a quantity of soft soap. Scrub the Vines with this and every part of the woodwork. Do not miss any hole or corner, as it is in these enough of insects may be lodging to restock the house immediately the Vines begin growth again. If the woodwork is deficient of paint, give it two coats, and limewash the walls thoroughly. After this some growers paint their Vines with a mixture of clay, soot, and sulphur, but we have ceased to do this, as the paint is apt to shut in some insects if any are left, and they will not fail to appear as the paint goes off, whereas if the Vines are left quite clean it can be easily seen if any pests come out later on.—J. M.

HEUCHERA SANGUINEA.

THE species of Heuchera most generally seen in gardens are more

FIG. 65.—HEUCHERA SANGUINEA.

valued for their foliage than their flowers, and at the base of rockeries they make beautiful clumps of green or bronzy leaves. One, however,

that is not at present so well known, though it is likely to become exceedingly popular, is *H. sanguinea*, illustrated in fig. 65, which for gracefulness and richness of colour far surpasses all the others. It is a hardy perennial, with neat little roundish crenately lobed green or bronzy leaves, from amongst which arise the tall slender graceful flower stems, each bearing a number of small flowers of a brilliant rosy red hue, a peculiarly pleasing and distinct shade of colour. Out of doors it thrives well in an ordinary border provided the soil be not too wet, and Mr. Ware has been very successful with it at the Hale Farm Nursery, Tottenham, while at Kew its characters have also been well displayed. As a border plant its value cannot be over-estimated, but it is also useful for another purpose—namely, in pots for greenhouse or conservatory decoration. The graceful habit of the plant fits it admirably for this work, and the brightly coloured flowers are seen to the best advantage disposed with Ferns or flowers of more delicate tints. At Kew several groups of the plant have been arranged on the shelves of the greenhouse during the past season, and the merits of this *Heuchera* have been demonstrated. It is easily increased by division, and probably also by seed.

SALADING IN WINTER.

LETTUCES.

As far as my experience goes the owners of large gardens are kept well or fairly well supplied with salading all the year round, but the case is very different in smaller places, those in charge of the majority of these failing to provide a good salad from the time Lettuces are over in the open till the earliest are cut the following season; yet it is by no means difficult to provide plenty of winter salading. The English do not profess to be a nation of salad eaters, but in spite of this supposed indifference I venture to assert nine-tenths of those who may take part in a public dinner do full justice to the contents of the salad bowl; and what wretched salads some of these are! Nothing better than quite green Lettuce or very slightly blanched Endive is principally used, and if this disappears so rapidly what would be thought of the crisp and beautifully blanched material such as may be found on many private tables at this time of year? As I shall attempt to prove, it is almost as easy to provide well blanched sweet and crisp salading as it is to have the inferior article, if only a little more pains were taken. At one time I was under the impression that nothing could equal Lettuce for laying the foundation of a good salad, but that was before I had developed a craving for a salad every evening. In reality, Lettuce from the time it ceases to blanch properly is inferior to well grown Endive, and fortunately the latter can be had in large quantities without encroaching upon space required by Lettuce or any other vegetable. Hundreds of plants can be had from a packet of seed, this being sown at fortnightly intervals, dating from near the end of July to the middle of August. According as the borders and open spaces are cleared of early Peas, Kidney Beans, Potatoes, Cauliflowers, and other early crops, for which the ground was well manured, these can be cleared, digging not being necessary, drills being then drawn with heavy hoes, well soaked with water or liquid manure, and planted with Endive. The Moss Curled is the earliest to arrive at maturity, this blanching without much trouble, and is also the first to succumb to frosts. In succession to this can be had any of the good forms of Green Curled, and this again may be beautifully blanched crisp and sweet by the time Lettuces fail, and a supply can be kept up through the winter. It blanches readily if tied up similarly to Lettuces, or it may be enclosed in flower pots covered with hay, boards, slates, and even moulded over, in the latter case being first tied up. For late autumn and winter supplies the Improved Broad-leaved Batavian is invaluable, this mixed with the Green Curled forming the principal ingredients of a perfect salad, no Lettuce being needed. Some of this may be blanched where grown, but the bulk should be reserved for winter use. Where so many fail with Endive is in being either too late in planting or in starvation treatment. If little beside a few outer leaves are formed they are comparatively worthless. A good heart is needed, and not till this is formed ought the blanching process to be commenced, as this stops all further growth, and when fully grown the hearts almost blanch naturally.

ENDIVE.

Where to keep it when grown may present a difficulty, but not an insurmountable one in but few cases. Quite young and only half grown Endive is nearly hardy, but fully grown plants are crippled by moderately severe frosts, and must therefore be protected in some way. We have them now, and at different times have stored the plants in a variety of positions, including the surface of borders in vineries, Peach and Fig houses, frames, open and covered sheds. All are carefully tied up and lifted if possible before the points of the leaves are injured by frost, and transplanted with a moderately large ball of soil and roots. Only those required for

immediate use are packed closely together and not untied, the bulk being so disposed as to admit of the plants being unloosed and opened out. They can be tied up again where placed, or better still, some can be taken to the Mushroom house, where the blanching is quick and perfect. In every instance the roots are firmly bedded among rich and fairly moist soil, this keeping the plants fresh, and does away with the necessity for overhead watering. I have known Endive to keep many weeks, or till midwinter and later, when tied and buried to the tips of leaves in sand.

If Endive is preferred to very early Lettuce, frame culture during the winter is necessary. A portion of the latest raised plants ought to be planted on a raised border and covered with frames and handlights, additional protection being given in severe weather. These will grow slowly, and if removed to the Mushroom house for the blanching period any plants that have survived in the open may be transplanted to the frames. Since the introduction of the very quick growing Paris Market Cabbage Lettuce there has been less need to provide Endive during the spring months. Small plants of the latter may be wintered with little or no protection, or they may be raised in heat early in the year. Being duly pricked out in frames, and set on a gentle hotbed, this Lettuce grows very rapidly and forms excellent hearts.

MISCELLANEOUS.

Other ingredients are frequently considered indispensable in the salad bowl, but unless they are tender and fresh they had far better be dispensed with. Tomatoes are usually served separately, and it is almost needless to add are very popular, but at the same time ought not to be mixed with other salading unless all who partake of the salad have a liking for them. Beet, when of good colour and tender, is an improvement to the appearance and flavour of a good salad, but I doubt the propriety of adding any other kinds of roots. A few young Onions are much liked by some, and these may be had by sowing the seed late in the autumn in boxes of good soil, these being kept in any cool house or pit. Mustard and Cress, either alone or mixed with the other salading mentioned, is usually appreciated. In many establishments it is sent to the breakfast table daily, and evidently finds favour. Though of easy culture it is not generally grown in a satisfactory manner. Instead of sowing seed repeatedly in shallow boxes of soil with only a fresh surfacing, a complete change ought to be made each time, and then there would be no complaint of damping and weakly growth. The boxes ought to be lightly drained and then filled with old Mushroom bed refuse and soil, this being moistened prior to sowing the seed very thickly on the surface. The seed should be pressed in evenly, but not covered with soil. Closely cover with brown paper or mats and set the boxes in gentle heat, the paths of a forcing house or early vinery being suitable position. Keep the shading on till the seedlings are about 2 inches high, when they may be uncovered and shortly afterwards transferred to a cooler house. Thus grown this small salading has long well blanched stems, is very tender, and quite free from grit. What watering is needed should be done very gently, and weekly sowings ought to be made.

Chicory is also largely used in salads, and may be said to improve its appearance, more especially when Endive is badly blanched, while the slightly bitter flavour is much liked by some. If several rows of seed are sown at the same time as Beet or Salsify, and the seedlings duly thinned, abundance of thick roots will be available for forcing, these being stored with other root crops till wanted. The tops ought to be twisted off, and the roots being placed thickly in pots and surrounded by good soil, and duly set in a Mushroom house or warm cellar or very gentle heat, will yield a surprisingly heavy and continuous crop of small hearts and leaves. Unless these are well blanched they are too bitter to use, and if neither a Mushroom house nor cellar are available, the blanching must be effected either with the aid of inverted flower pots with their holes stopped, or somewhat similar contrivance. A dozen 10-inch pots would afford a good succession. Curled Chervil sown on a warm border in September and covered with a frame can be picked from throughout the winter, and Tarragon can be had by lifting the roots and forcing these in any heated house. Corn salad, unless exceptionally well grown, is rough to the palate and tough, and this is never used here. Celery is frequently used in salads, a few Watercress, and which are easily cultivated in pots, pans, and boxes, are always a welcome addition, and a floury Potato may be finely divided with a fork and scattered over the salad with advantage.

PREPARING A SALAD.

Although the foregoing remarks are somewhat lengthy, I shall yet venture to state my ideas upon the subject of preparing the ingredients and dressing of a good salad. Freshness is the greatest desideratum, a flabby and flat salad being most objectionable. What gardener has not had good and frequent cause of complaint against those responsible for preparing the salad? Either it is made three

or four hours before it is wanted, or proper care is not taken of the vegetable portion of the salad, Lettuce, Endive, and other ingredients being left in an exposed and perhaps hot position to flag badly, and this freshness once lost cannot be restored. Nor should they be kept in water for hours together, this frequently destroying crispness. The living portion of a salad ought to be gathered a short time, or not more than four hours at this time of year before it is wanted, and should be kept in a cool place both before and after it is washed and otherwise prepared. A moderate-sized salad might consist of two each of Green Curled and Broad-leaved Endive stripped of the green outside leaves, and not very finely shredded, to these being added about a dozen young Onions, a small handful each of Mustard and Cress, two hard-boiled eggs, and a small Beet duly sliced, one floury Potato, and about six sprigs each of Tarragon and Chervil. There are a variety of dressings for salads, some being very simple, yet good, and others more elaborate. Personally, I am in favour of a simple dressing, and prefer the French style of keeping these in a suitable bottle or other receptacle, individuals at the table taking as much as they like. Nor are some persons content with one kind of dressing, as, for instance, some people have a marked aversion to oil, others being fond of it, and two or more dressings would be more likely to meet all tastes. Much-minced and be-soaked salading would also be avoided. In conclusion, I will add a receipt for a simple dressing suitable for those who do not keep professed salad-makers and for gardeners. Place one teaspoonful of mixed mustard and one teaspoonful of pounded sugar into a bowl, and add two tablespoonfuls of good salad oil, drop by drop, and carefully stir these together. Next gradually add four tablespoonfuls of new milk and two tablespoonfuls of vinegar, with cayenne pepper and salt to taste. All must be carefully stirred together, or the sauce will curdle. This dressing may be either poured direct into the salad bowl, or else kept in a bottle, being available at least two or three days.—W. IGGULDEN.

ORCHIDS IN FLOWER AT KEW.

CONSIDERING that only comparatively small sums have been expended in purchasing Orchids at Kew, and that the greater portion are gifts or have been obtained in exchange, it is surprising what a large and interesting collection has been formed. The houses, open to the public at all times, contain some rare or beautiful plants in flower, and though I am a frequent visitor I have never yet entered this department without finding something of a noteworthy character. Extensive displays of a few species are not attempted, these can be seen in nurseries or private gardens, and the object of a national collection should be to provide as good a general representation of the Orchid family as possible. This is evidently what the authorities have been endeavouring to do for some years, and the result of their efforts is seen in a steady improvement both in numbers and condition.

INDIAN CROCUSES.

It was an excellent idea some time ago to provide a porch to the cooler of the two houses, as they can be utilised for those plants that require only the coolest quarters; and it answers a further purpose, as by means of the outer and inner doors the admission of cold draughts of air on to the more delicate plants is avoided. In ordinary private gardens this is a matter of importance, but in a public establishment visited by so many persons as Kew is, it cannot be over-rated. This porch is principally employed for Sarracenias, Droseras, the Dionæa, and similar plants, but during the past month or so it has been occupied with those charming little Orchids, the "Indian Crocuses," Pleiones, or Cœlogynes as we must now call them according to that great work, Hooker and Bentham's "Genera Plantarum." In shallow pans of moss the pretty little delicately tinted flowers cluster round the small leafless conical pseudo-bulbs in great numbers, almost concealing both plants and moss. Pleione Lageraria, with pale purple sepals and petals, the neat lip fringed, blotched crimson, purple, and yellow in the centre, is one of the earliest and most profuse flowers. P. maculata is a charming contrast, the sepals and petals white, the lip spotted and streaked with purple, very free, and easily managed like the first named. Then there is P. Wallichii, one of the most handsome of all, with larger flowers, sepals and petals of a rich clear purple, the lip fringed white or blush, and a pale yellow centre. Owing to these plants

flowering without their leaves, small Ferns are sometimes planted with the pseudo-bulbs to furnish a foil of green, but if plenty of fresh, green, healthy sphagnum is employed, these are scarcely necessary. After the flowering, when the light green leaves begin to expand, the Pleiones are almost as pleasing as previously, the tint of green being a peculiarly refreshing one in contrast with the darker or duller green shades prevailing in Orchid foliage generally.

MASDEVALLIAS.

The collection of Masdevallias at Kew is becoming very large and interesting, but it necessarily includes a considerable proportion of the small-flowered species which are too often regarded simply as botanical curiosities. It cannot be claimed for them that they furnish much in the way of colour to an Orchid display, but genuine plant lovers require something more than mere brilliancy of colour to interest them. The Masdevallias present a wide range of floral characters both as regards form and size, and it is regrettable that the often suggested illustrated monograph of the genus has never yet been produced. Some time ago it was said that a titled gentleman in the north had undertaken the task at his own expense, and I believe large numbers of accurate drawings were prepared by a lady artist. I also understand that Mrs. Dyer of Kew has for a long time been engaged upon drawings of these curious plants, and her collection now must be almost unique. Those who know the excellent work performed by the lady named in plant-sketching will readily understand that the Masdevallia drawings are both artistic and botanically faithful, and it can only be hoped that at some future time they will be presented to the public.

Amongst the Masdevallias in flower were *M. melanopus*, *M. macroura*, *M. polysticta*, *M. ochthodes*, *M. Reichenbachiana*, *M. pulvinaris*, *M. Chelsoni*, *M. Carderi*, *M. platyglossa*, *M. bella*, and *M. ignea*.

Of other Orchids in flower, to which on another occasion an additional note or two may be devoted, were the following:—*Cypripedium insigne* (quite a large bank of flowers), *Spicerianum*, *Sedeni*, *porphyreum*, *calurum*, *Leeanum*, *Harrisianum*, *conchiferum*, and *Roezli*. *Disa purpurascens*, one of the blue flowered Cape Orchids introduced by Mr. Watson; *Epidendrum* (*Barkeria*), *Lindleyanum*, *Oncidium tigrinum*, *Odontoglossum crispum*, and *O. Rossi* varieties; *Miltonia candida*, *Lælia anceps Barkeriana*, *L. autumnalis atro-rubens*, *Cirropetalum Wallichii*, *Catasetum macrocarpum*, *C. fuliginosum*, *Cymbidium giganteum*, *Calanthe Veitchii*, *C. vestita*, *C. veratrifolia*, *Liparis pendula*, *L. spathulata*, *Trichopilia suavis*, *Cœlogyne fuliginosa*, *C. fimbriata*, and *Maxillaria venusta*.—C.

USEFUL WINTER ORCHIDS.

CALANTHES.

LATE supplies of these plants will be invaluable for the conservatory now that Pelargoniums and other autumn-flowering plants are past their best. Do not place them in this structure before nearly all the flowers are expanded and the soil is perfectly dry in the pots. The flowers will last nearly double the length of time in a temperature of 45° to 50° than would prove the case if kept in the warm moist atmosphere of the stove. Be careful to place the plants where they will be free from drip, and where the atmosphere is moderately dry. In a low temperature and moist atmosphere the flowers are very liable to become spotted. Arrange them so that the pots are hidden by surrounding objects and the spikes of bloom stand well above other plants.

DENDROBIUM NOBILE.

Few plants when well flowered in 6 and 7-inch pots, or even larger, add more to the effective appearance of the conservatory at this period of the year than this old inhabitant of our plant houses. If the soil about the roots is dry before removal to such structures, and it is kept in that condition during the whole of the time they are there, no harm will follow; on the contrary, the plant will be benefited by the change. The flowers are so useful in a cut state that they must not be allowed to remain upon the plant long enough to rob next year's growth of the support which is necessary until they are well rooted and independent of the old flowering pseudo-bulbs. This plant can be used with safety in rooms provided it is not kept in too long or arranged where cold draughts will strike upon it.

ODONTOGLOSSUM ROSSI MAJUS.

Unquestionably one of the best and most profitable Orchids that can be grown where decorative plants are required in quantity, either for the room, conservatory, or for flowers in a cut state. By growing a good number there is no difficulty in having a succession of flowering plants from the middle of October until the middle of February. For single vases, pans of this plant 5 or 6 inches across, carrying six or seven spikes, with an average of three flowers on a spike each, are admirable.

PHAJUS GRANDIFOLIUS.

Very useful plants for the conservatory, and if they are wanted in bloom as quickly as possible place them in brisk heat, and their

flower spikes will advance rapidly. Directly the first flowers are open gradually harden them to cooler treatment before they are taken to the structure in which they are needed to do duty. Be careful to keep the soil dry at their roots. Give no more water than will retain their foliage in fresh and healthy condition. When water is needed apply it tepid. The plants are liable, when in flower, to attacks of brown aphides. Remove them, if they appear, with the sponge.

COELOGYNE CRISTATA.

Plants that were grown in a warm house, and have had a lengthened rest in a temperature of 50°, will be pushing their flower spikes rapidly. In order to provide a succession of these flowers introduce a few of the plants into a temperature 10° higher. The remaining portion of the early supply can remain where they are for the present, while later grown plants may be rested in a temperature of 45° to 50°. Do not overwater those at rest; give only sufficient to keep the pseudo-bulbs plump.

THE ODONTOGLOSSUM HOUSE.

Watch diligently for slugs in this structure, for they are generally a source of great annoyance at this season of the year. Every effort to destroy them should be made, for if left alone they will soon do a large amount of damage now that the flower spikes are appearing freely on *O. Alexandriae* and *O. Pescatorei*. We have found a light syringing of petroleum and water, 1 oz. to 4 gallons of water, syringed on the stage amongst the pots, a capital plan for driving slugs from their hiding places to seek more genial quarters, when they can be captured. After syringing, if plenty of Lettuce leaves are laid about, they will quickly take possession of them, when under ordinary circumstances they would not have touched them. Dry cotton wool placed round the growing spikes proves a good preventive against slugs, but directly it becomes wet it is no hindrance to them. The best way to catch slugs is to examine the plants with a light about an hour after it is dark, after thoroughly damping the stage and pots.—ORCHID GROWER.

THE CHRISTMAS HOLIDAYS.—In consequence of the pages of this issue of the Journal having to be prepared for press nearly a week in advance, the publication of many valuable articles, including notes on new Chrysanthemums, Orcharding, Grapes, Auriculas, and various other subjects, must of necessity be deferred to a future issue. We thank all our correspondents for their co-operation in enabling us to complete two issues of the *Journal of Horticulture* in one week.

— AT the dinner of the CARDIFF CHRYSANTHEMUM SOCIETY recently there was a good attendance of members, representing the chief gardeners in the district. The Secretary, Mr. C. R. Waldron, stated that the balance in the bank after all expenses were paid is £49 3s. 9d., a very satisfactory condition.

— NEW FANCY PANSY, MRS. B. WYNNE.—Mr. John Downie of Edinburgh sent me in the middle of November a bloom of this very fine seedling of his, which is, I think, to be sent out in spring. It is a grand flower in form, size, and substance, rich in colour, with an immense clearly cut blotch.—W. D., *Solihull*.

— MANY of the *Salvias* are useful for culture in pots during the winter months, and one of these, which is not so frequently grown as others, is *SALVIA LEUCANTHA*. It is of bushy habit, bearing long narrow leaves and tall spikes of white flowers, the calyxes of which are woolly and of a soft mauve tint. This *Salvia* is very free in flowering, and in contrast with the bright *S. splendens* or the beautiful blue *S. Pitcheri* it has a capital effect in a conservatory.

— IN such an exceptional season as the present so many plants have been recorded as flowering out of doors that some gardens have presented quite a spring-like appearance. We have had plenty of Primroses, some Violets, and other plants in flower for weeks, but one of our favourites is *STERNBERGIA LUTEA*, which has been bearing its golden flowers for some time past, but is now losing its attractions. A small bed is formed of the bulbs, and, as every one flowers, they produce a good effect if planted rather closely together in rows. They are dwarf,

the leaves narrow and dark green, the flowers peeping up amongst them.—L. W. S.

— IN addition to the letter on seedling Sugar Canes in another page, the "KEW BULLETIN" FOR DECEMBER contains information on the Inhambane Copal (*Copaifera Gorskiana*), several other species of the same genus in Africa also affording copal. The tree produces a hard and valuable timber, but it has not been long known that it yielded copal of commercial value. Specimens, with fruits and seeds, were introduced to Kew by Mr. Heathcote in 1886. Several hundred seedlings were raised and despatched to many of our tropical colonies. The cultivation of Rice in Bengal is the subject of an article. To the Silkworm Thorn (*Cuchania triloba*) a chapter and illustration are devoted. Jamaica Indiarubber (*Fosteronia floribunda*) and Ramie (*Boehmeria nivea*) are also treated upon. This number completes the volume for 1888, comprising 298 pages, and dealing with a variety of subjects of special importance to those interested in colonial resources.

— THE ROYAL METEOROLOGICAL SOCIETY has published its "Meteorological Record" for the first quarter of this year, containing the monthly results of observations made at its stations, with remarks on the weather by Mr. W. Marriott. The Society commenced the organisation of stations on a uniform plan in 1874, and these were supplemented by another class of stations, termed climatological, in 1880. Since 1881 the results have been published in a separate form under the above title. A map of the stations is issued annually, and shows that they are fairly well distributed, except in Wales. In addition to the monthly results, tables of daily rainfall are given for a number of stations, and of the daily temperature and sunshine in London and the suburbs. The monthly values published by the Registrar-General are also appended, and the whole forms a valuable record of the meteorological statistics of England and Wales, issued well up to date.

— AT a meeting of the FRENCH METEOROLOGICAL SOCIETY on November 6th, M. Lemoine presented a summary of the rainfall observations of the basin of the Seine in 1887. He stated that the rainfall was everywhere below the average; in the Department of the Seine-Inférieure the totals for the year were the lowest in a series of twenty-one years. M. Renou stated that the late M. Hervé-Mangon having expressed the wish that his observations made at Ste.-Marie-du-Mont should be published, Madame Mangon had handed them over to him for publication at her expense. M. Renou presented a note on the temperature of October at Paris since 1757. He pointed out that during the last 130 years the month of October presented either a low or a high mean every twenty or twenty-five years. Means as low as that for October, 1887—viz., 44.1°, were very rare. Since 1757 the lowest averages for October had occurred in 1784 (45.3°), and 1817 (45.1°).—(*Nature*.)

— SOME reference was made recently to a note published respecting a collection of BOTANICAL OBJECTS FROM COREA sent to the Kew Museum, and the following further particulars are interesting. "Some of the hand-screens presented by Mr. Watters to the Kew Museum were given to him by the King, and are of much finer workmanship than those that are purchasable. The oil-steeped paper tobacco-pouches and hat-coverings are a close imitation of oilskin; the latter, which when opened is conc or tent-shaped, is used by all classes except the peasantry, even including the soldiers. The Korean boy's kite, which is also made of Broussonetia paper, consists of a piece of paper about a foot square with a circular hole in the middle, kept in form by thin strips of bamboo; a thin string is attached to each corner and brought together and connected to a single string, which is wound upon a wooden windlass. The perfection of splitting bamboo into thread-like strips seems to be divided equally between the Chinese and the Koreans, judging from a remarkably fine example of a blind which forms one of the exhibits. These very fine blinds are said to be used only by high mandarins, and the coarser kinds by the lower classes. Another illustration of very fine work is in the utilisation of split rattans in the manufacture of articles of clothing, an undershirt and cuffs of very open ornamental workmanship being made entirely from this material, which is both soft and pliable. These shirts are said to be used next the skin in hot weather to prevent the outer shirt adhering to the body."

— TOMATOES.—I have been growing about half a dozen sorts of Tomatoes in a good-sized house, and on the centre flat stage we planted in a shallow bed of turfy soil and manure, and many wonder that they do so well on so little soil. The side stages are filled with plants in pots, all in 6-inch and 8-inch, with no manure under them, only occasional manure waterings and plenty of water. I grow Hackwood Park Prolific,

because it is one of our all-round best varieties ; a good size (I have one plant in an 8-inch pot with a dozen fruits, each from 5 to 6 ozs. in weight, besides smaller ones). Sutton's Reading Perfection is a very fine variety, and weighs heavily, more so than Hackwood Park, but does not crop so heavily, but it is a variety to grow. I planted out a number of plants of Laxton's Open Air and Sutton's Earliest of All, but it was a failure, owing to the season. I also potted a good many into the 6 and 8-inch pots, and with the treatment I have named they have done exceedingly well, both being good croppers, a fair size and early. For under glass I shall always grow them, because they are early and do not grow so strong as some other sorts, but it will be Sutton's that I shall prefer of the two for indoors. What the two varieties will do out of doors, the cold wet season prevented me from ascertaining. I had them planted against walls and the open ground, but in each case they failed. I think that too much root-room and feeding is a mistake, also growing the plants so fast. Ours were grown in cold frames as young plants, and no heat used after planting until the weather was so wet and cold. I have out-distanced in crop and health many of my neighbours who have much better accommodation, for such free growth has, in conjunction with the sunless season, led to failure.—W. D., *Solihull, Birmingham.*

— THE annual dinner of the MIDLAND COUNTIES AND BIRMINGHAM CHRYSANTHEMUM SOCIETY was held on Tuesday evening, December 18th, in the Bell Hotel, Birmingham. After ample justice being done to the dinner provided, Mr. Latham, the Chairman, proposed the health of "The Queen," which was most loyally responded to. Mr. A. Outram proposed "The Society," and spoke favourably of the same, stating it was one of the best managed shows in the provinces and a great credit to the City of Birmingham. The toast of "The Exhibitors" was responded to by Messrs. Cooper and Dyer. "The Officers of the Society" was proposed by Mr. Dyer, the same being responded to by Mr. Hughes, the Secretary, and Mr. Jones, the Treasurer, the former stating it was their intention next year to offer liberal prizes to induce the growers from a distance to compete. A subscription list was at once opened, and several guineas subscribed. We wish them every success in this their intention. Mr. Jones read a report of the financial condition of the Society. It was gratifying to hear the balance was on the right side. "The Nursery and Seed Trade" was proposed by Mr. Cooper and responded to by Messrs. Pope and Spinks. "The Promoters of the Society" was responded to by Messrs. Gilbert and Lea, who were amongst the first to start this progressive Society upwards of thirty years ago. The toast of "The Visitors" was responded to by Messrs. Petch of Worcester and Mr. Sydenham. Mr. Crook proposed "The Chairman and Vice-Chairman," both of whom responded. The evening was a most enjoyable one, and some good singing was rendered by some of the company present, of whom there were upwards of fifty, including many from a distance.

— IN the address of the President at the anniversary meeting of the ROYAL SOCIETY, the following reference was made to Sir F. von Mueller:—"A Royal medal has been awarded to Sir Ferdinand von Mueller for his long services in Australian exploration, and for his investigations of the flora of the Australian continent. For more than forty years von Mueller has been working, without intermission, at scientific botany and its practical illustrations. As a botanical traveller and collector he has, to quote the words of Sir Joseph Hooker, 'personally explored more of the Australian continent than any other botanist except Allan Cunningham.' No one has investigated the Australian flora and the geographical distribution of its components with so much perseverance and success, and no one has enriched our herbaria, laboratories, and gardens with materials for study to so great an extent. The eleven volumes of the 'Fragmenta Phytographiæ Australiæ' contain the descriptions of a great series of new plants, and the unrestricted communication of his collections and observations to the late Mr. Bentham rendered possible the preparation of the 'Flora Australiensis,' in seven volumes, the only account of the vegetation of any large continental area which has at present been completed. He has especially devoted himself to the elucidation of the most difficult though most characteristic groups of the Australian flora; and as a result of his labours in this direction his 'Eucalyptographia' may be more particularly mentioned, a work which will always be the standard of nomenclature for the intricate genus *Eucalyptus*. Of a similar character are his descriptions and illustrations of the 'Myoporinæous Plants of Australia,' and his 'Iconography of the Genus *Acacia*.' To him is also due the foundation of the Government Herbarium at Melbourne, the first great botanical collection formed in the southern hemisphere, and the future centre of all scientific work on the Australasian flora."

— THE Earl of Meath, writing in one of the daily papers, calls attention to the proposed VAUXHALL PARK as follows:—"The part of Lambeth in which it is proposed to preserve these eight acres of land is one of the most densely populated localities of the metropolis, and there is not, with the exception of Kennington Park, any open space within two miles. The proposal was initiated some two years ago for securing these lands as an open space, but the pecuniary difficulty which invariably occurs in such cases presented itself with very great force on this occasion owing to the high value which property in this locality commands. Without going into details, it is sufficient to state that the Committee which was formed, after having overcome almost insuperable difficulties, obtained an Act of Parliament last session enabling the Vestry, the Metropolitan Board of Works, and the Charity Commissioners, out of the City of London Parochial Charity funds, to contribute towards the expenses of acquiring the land, and both the Kyrle Society and the Metropolitan Public Gardens Association have associated themselves with the scheme. An agreement has been come to with the owner for the acquisition of the land for £43,500, which, with attendant expenses, raises the sum required to £45,400. After deducting the amount to be obtained from the sources named and the subscriptions already received, a balance will remain of about £7000 still to be provided. I would therefore, as Chairman of the Metropolitan Public Gardens Association, invite the many friends of the open space movement and those who have not long returned from their annual autumn holiday to assist in providing what is after all but a poor substitute for Scotland, Wales, or Switzerland, or the beautiful English country side, for the poor toilers of Lambeth. Donations may be sent to the office of the Association, 83, Lancaster Gate, W."

— STRAWBERRY CULTURE IN THE UNITED STATES.—An American paper relates that a young man named Wilson twenty years ago bought 13½ acres of land west of Centralia, Illinois, and set out Strawberry plants. These then were almost as much a rarity as a four-leaved Clover, and the people thought the man crazy and nicknamed him "Strawberry" Wilson. But this was the beginning of an industry which has since loaded 190 earloads (2,097,600 quarts) in a season of twenty days, and once 25 earloads in one day, bringing to Centralia from 125,000 dollars to 150,000 dollars, and paying out to pickers 55,000 dollars. A earload is 460 crates of 24 quarts each. Growers who have had experience in other places find in the soil about Centralia and the climate peculiar advantages for the Strawberry; the only problem is the market, and improved shipping cars are widening the latter. About 2000 acres are planted; the largest patch is of 30 acres, but the smaller ones pay best. From one-eleventh of an acre 1040 quarts were picked, selling for 104 dollars. A young lady, from 16 square rods, sold 560 quarts, besides supplying the family table. Nearly all the back yards in Centralia thus bring in pocket money. The Crescent, Minor's Profit, and Warfield are leading berries with large growers. Two crops are taken from a planting. Sunday berry picking is on the decline, as growers have found that their fields can be left from Saturday noon to Monday morning without danger. Mr. Townsend, who employs 475 pickers, has done no Sunday picking for five years. Thinking their crates cost too much, the Centralia growers this year formed an association to manufacture them, using a large brick skating rink for the purpose. When the rush came, 57,000 crates with their boxes were ready, costing 12½ cents instead of 18 cents, and as about 120,000 crates are used, the saving was 6000 dollars. Poplar strips from Tennessee are used for the boxes, and an expert will turn off 72,000 daily, tacking by machine.

— A PAPER by Mr. Colchester Wemyss was read at a MEETING OF FRUIT GROWERS IN GLOUCESTER recently, which we reproduced on page 519. In the course of a discussion subsequently Mr. Campbell made some interesting remarks, of which the substance is here given. He said that for many years he farmed in Cheshire, and then travelled on the Continent, living for many years in France. Following the advice of a paper by Mr. Charles Whitehead he determined that if ever he came back to England he would start fruit growing, and his lot in life had led him to be near Ross, in Herefordshire, where he had a place admirably suited for fruit growing, and a good climate, which they found sometimes was a little too dry. One of his first experiments was to plant Plums, in addition to Apples and Pears. He planted an acre of Victoria Plums, having 680 trees to the acre and giving them a space of 8 feet. He planted them about five years ago, and he would now tell what they had done for him up to the present time. They must bear in mind he had everything in his favour. He had a good and competent gardener, and they took the utmost pains in grading their fruit. They

did not send their fruit to market packed higgledy-piggledy, and he had sent fruit to market so carefully packed that the dealer had written saying it was not necessary to take such trouble in packing it, but they might depend upon it it was. The first year he got a crop of 13 cwt., the second year he doubled it, last year he got 4 tons, and this year between 4 and 5 tons. As to the market being glutted, it was not by high class produce but by inferior fruits. If they planted a first-class Plum, Pear, or Apple, and took pains with it, they would never have a glut. This year he had made something like £50 for his acre of trees, which followed on rather more than £40 last year. He hoped he should be able to tell them on some future occasion he got £120 an acre, which Mr. Bunyard said they ought to get. In reply to questions, Mr. Campbell said his Plums were entirely Victorias, and there had been comparatively few deaths of his trees. He made one great mistake through ignorance of his land, by not draining it, and one day he found it waterlogged from the water off the hill above, but now it was drained his trees were going on all right. He fixed on Victorias simply because they were the most marketable. They were eating and preserving Plums, though in some markets he agreed they would not sell. In Evesham they would prefer the prolific sort. He obtained 3s. 9d. for 24 lbs. of his own Plums in Leominster market. He sent the whole of it away, having no refuse. His fruit was pretty much the same quality and size. One learnt a great deal by experience, and it was his intention next year to take all the bad fruit from every tree—he had some 5000 or 6000 trees—and thus throw all the strength of the tree into the remainder of the fruit, and when market time came he should absolutely have not a single fruit to throw away.

— FOLLOWING on the same subject Sir W. Wedderburn said they had two enemies to deal with; one was the foreign competitor, and the other was the home distributor. Therefore they must see what they could do themselves; they must not lie down in a feeble way and allow themselves to be ridden over. Co-operation was the best means of coping with these two enemies, and he therefore proposed, "That it is desirable to form a local association to aid the home grower of orchard and garden produce in competing with the foreign producer both in the home and the foreign markets; and that the co-operation of those interested in horticulture be invited in order that practical and detailed information may be supplied to local producers as to the best and most profitable methods of raising and selling choice varieties of fruit, vegetables, and flowers, and getting them to market." The foreigner chiefly got the better of the home producer by raising early things and very choice varieties. Still we saw quantities of produce brought from the Channel Islands and France which might be produced here, and he believed the English article would fetch a price 20 per cent. higher than that of the foreigners. A good deal had been said against the middleman, but they must remember that if he was given a great deal of ungraded, miscellaneous, and untrustworthy produce, which he had to grade, find a market for, and take the risk of loss, he must be expected to take the profit. If information as to markets were disseminated, they might, by working together, take over all those profits taken by middlemen. The general objects of such an association would be by public meetings and conferences to bring together practical men, and get good opinions and information. Detailed and practical information with regard to special subjects might be disseminated by means of leaflets, and an experienced horticulturist might be engaged to go about from one district to another communicating the methods and practices which had been found most successful to the fruit growers."

SEEDLINGS OF SUGAR CANE AT BARBADOS.

THE Sugar Cane (*Saccharum officinarum*, L.) is one of the most valuable economic plants we possess. It has been cultivated for so long a period that the primitive habitat of the species, according to De Candolle, is unknown—"Origin of Cultivated Plants," 1884, p. 755). Bentham in "Flora of Hong Kong," p. 420, states that "We have no authentic record of any really wild station of the common Sugar Cane." Further than this, in common with many plants that have been for a long time under cultivation and reproduced solely by means of buds and suckers, the Sugar Cane so rarely produces mature fruits that no one, as far as we are aware, has ever seen them. Certainly in the rich Herbarium at Kew there are no seed-bearing specimens. In botanical works the subject is often referred to, but apparently only to restate the fact that botanists like McFadyen in the West Indies and Roxburgh in India "have never seen the seeds of the Sugar Cane."—"Hooker's Botanical Miscellany," 1830, vol. i., p. 95, tab. 26).

Schacht is one of the few persons who has given a good analysis of

the flower of the Sugar Cane including the pistil; he also had not seen the ripe seed.

In discussing the problem how far the saccharine qualities of the Sugar Cane could be improved on the same lines as those so successfully adopted with regard to the Beet, it was lately pointed out in a letter addressed to the Colonial Office that, owing to the power of producing fertile seeds having apparently been lost by the Sugar Cane, it was impracticable to deal with it by means of cross fertilisation, or by the ordinary course of seminal selection. It was further pointed out that new and improved varieties amongst Sugar Cane were to be looked for amongst bud variations, and planters were advised to mark any canes that showed a departure from the type and cultivate them separately for experimental purposes, with a view to test their yield in sugar. Attention having thus been directed to the subject by official notices published in sugar-producing colonies, several communications have been received at Kew from persons who believed that they were able to afford some information on the point whether the Sugar Cane produces seed or not.

First, as regards the actual seeds of the Sugar Cane. A correspondent at Fiji, in forwarding a small packet to Kew in April last, stated, "Some time ago there was published in the Government Gazette of this colony an extract from a letter from you in reference to Sugar Cane seed. I have been eighteen years in sugar-producing countries, and have never observed Sugar Cane seed until within the last month, when one of my sons brought me a head fully ripened from a garden in my neighbourhood. Some time afterwards I went to see the sort of cane from which the seed had been gathered, but the plant was dug up and I could only learn that it was a purplish cane." The seed sent by this correspondent proved not to be the seed of a *Saccharum* at all; it was the seed of a *Sorghum*, and probably of *S. vulgare*, the common Millet or Guinea Corn.

Recently, however, a statement has reached Kew, from a trustworthy source, that seedling Sugar Cane had been found at Barbados, and that plants were in course of being raised at the botanical station in that island, under the care of Professor Harrison and Mr. Bovell. Mr. J. B. Harrison is Island professor of chemistry and agricultural science at Barbados, and in conjunction with Mr. T. R. Bovell, who is superintendent of Dodd's Reformatory, he has been engaged for the last three years in cultural and chemical experiments with various kinds of Sugar Cane. The results of these experiments have been published officially by the Government of Barbados, and afford data of a valuable character as regards the effects of manurial constituents applied to Sugar Cane, as also the relative merits of new and old varieties of canes now under cultivation in the West Indies.

The statement sent by Professor Harrison appears to prove, in a perfectly natural and circumstantial manner, that a few mature seeds may occasionally be produced by the Sugar Cane under certain circumstances. It is stated by Rumphius that the Sugar Cane "never produces flowers or fruit unless it has remained several years in a stony place." He does not, however, say whether he ever saw the fruit, nor does he cite any proof of the fact in the shape of seedlings, self-sown or otherwise. The canes that would be likely to produce fruit would be those varieties nearest to the original wild cane, and probably on that account they would be less rich in sugar than the canes improved by a long course of cultivation. Without expressing a decided opinion on the subject, and in the absence of the specimens themselves, the information supplied by Prof. Harrison is, so far, the most tangible of any yet received to show that the cultivated Sugar Cane may occasionally produce mature fruits.

"On certain of the higher districts of the island from time to time growths of Sugar Cane resembling fine grass have been noticed, but in most cases no attempts have been made to cultivate them. Mr. Parris some years ago succeeded in raising a few canes from the cane arrow or flowering shoot. Mr. Clarke did the same with the arrow of the purple transparent cane, but did not succeed in getting the seedlings to flourish, and my wife's father many years ago succeeded in getting the arrows to produce young canes, but not in cultivating them. Knowing these cases, Mr. Bovell and myself considered that a favourable opportunity of examining into this question offered itself during the cultivation of the varieties of canes which we have here. These canes were planted in rows of four broad by 25 feet deep, and so as to have two sets of each kind, in all 36 plots of 18 varieties, planted side by side. The plots were noticeable this year for the number of arrows sent up by some of the varieties. We gave strict orders to the labourers employed in weeding and watching the adjacent land to report to us any grasses springing up upon them in any way differing from the usual weeds. Towards the end of January they reported to us that a few tufts of grass different to the usual kinds were making their appearance. We found these to be growing in a rather narrow belt of the field on one side of the plots and in a little below it, following the direction of the prevailing wind. They were found not only on the surface of the field, but also on the bottom of a drain which had been dug in the field to a depth of 18 inches. Some eighty or ninety plants sprang up at intervals afterwards. We found a good deal of difficulty in keeping them alive, as the sun quickly shrivelled them up; it was necessary to protect them in many cases from the direct rays of the sun and to keep them constantly watered. In this way we succeeded in saving some sixty-four or sixty-five plants. Of these we carefully examined three or four so as to ascertain as far as we could the absence of any particles of old cane in them. Their mode of growth was quite different to that of canes growing from the eyes of canes. Sixty plants were successfully transplanted, and are being cultivated. At present they are not far enough advanced in their growth to

speaking with certainty, but there appears to be amongst them several different kinds, probably five or six at the least. If you think it worth while, Mr. Bovell and myself will send you a specimen cane of each sort in January or February next, when they will be sufficiently far advanced to show their characteristics. The way in which they first grow is quite sufficient to account for them not being often noticed upon the fields. The weather here during January last was particularly favourable for their growth, and the fact of different varieties being grown side by side is, of course, much more favourable for the production of seed than the

SKIMMIA FOREMANI.

WHAT are popularly known as "Berryed Plants" are always valued for decorative purposes, and this is particularly the case when the berries are of a bright colour, freely produced, and long lasting. At the Royal Horticultural Society's meeting on December 11th last Mr. Foreman, Eskbank Nursery, Midlothian, exhibited a *Skimmia* under the name given above, which was said to have been raised at

FIG. 66.—SKIMMIA FOREMANI.

growth of one variety only. I have never heard of the Bourbon cane producing here fertile arrows; in all the alleged cases of fertility the arrows were either those of the purple or white transparent varieties which, as you are aware, are prone to variation. We shall again attempt this year to obtain the same results. I am anxious to have the benefit of your opinion upon this year's results, as of course, if we can establish the fact of the cane occasionally, and, under certain favourable conditions, producing fertile seed, it will open an important field of investigation.—J. B. HARRISON, Government Laboratory, Barbados, 17th September, 1888.—(*Kew Bulletin*.)

Eskbank from seeds obtained by crossing *S. oblata* with *S. fragrans*, and so attractive was the plant with distinctive characters well marked, that a first class certificate was awarded. The leaves are dark green, of oval form, the bright scarlet berries being produced freely in large bunches, and they are described as remaining on the plant for a considerable time, some being retained for two years. The plant is of sturdy compact habit and very hardy, for Mr. Foreman says it has been exposed to 32° of frost without injury.

REVIEW OF THE PAST SEASON.

HAVING had opportunities of seeing Chrysanthemums in various parts of the country during the last five weeks a few notes on this subject may not be wholly uninteresting now that the exhibitions are over and when intending cultivators for next year are considering how difficulties may be overcome and pleasures afforded by a better knowledge of the many requirements of the Chrysanthemum in our fickle English climate. It cannot be said that this has been a good year for the production of high-class blooms in any section, but there have been plenty in number to provide rich treats for the ever-increasing Chrysanthemum-loving public. The season has been on the whole a bad one for growers, though it did not entail so much work in procuring and applying water to the plants as that of 1887; indeed the excessive supply this year caused great anxiety, and it was not pleasant to anticipate the consequences. I have long thought that to produce Chrysanthemums in the finest condition entails more incessant care and anxiety in the multifarious details of culture than in the case of any other plants, and that the best efforts are sometimes rendered nugatory by the weather.

No sooner are the plants in flower than attention must be directed to the next season in carefully selecting new varieties, determining their merits and looking for faults in every conceivable form, so that space is not uselessly occupied and labour wasted on inferior varieties. Choosing the best is the commencement of the coming year's programme. The next step is the preparation of the plants for obtaining the necessary cuttings, which will eventually be expected to produce winning blooms another year; but I fear I am digressing from the text somewhat.

As before stated this has been on the whole a bad season—a sunless spring, a cold May, a wet June, and a wetter July, accompanied with cold days and nights, the thermometer falling as low as 42° during one night in June. This kind of weather was bad for the plants which had just been transferred to their final pots, causing a serious check to root-action and injuring the foliage, the plants receiving far too much water before the roots had time to take hold of the new soil; and this was not improved by being continually washed. July was even worse than June, rain falling in such abundance that some collections of plants hardly required water artificially for three weeks at a spell, and the temperature fell as low as 39°, while on several occasions it was below 45°.

The incurved blooms generally have lacked that depth and symmetry of form so pleasing to the cultivator. There have been too many loose open blooms and small petals in the centres owing to the non-maturation of the wood, the plants not being equal to finishing the blooms in the important point called “filling up.” There has been a considerable tendency on the part of some varieties, notably Alfred Salter and Golden Queen of England, to unfold the lower half of the flowers satisfactorily, the remaining florets coming reflexed, thus preventing the blooms becoming perfect specimens of their respective varieties. Many blooms, not only among the Queen type but others, showed cross centres, or several centres, consequently quite useless for exhibition. Many varieties showed a want of substance in the petals, causing them to stand erect instead of incurving, hence so much roughness and want of finish. Flat blooms have been common, especially among the Queens, owing to the centre petals in some instances refusing to unfold properly, and removing these bad centres reduces the depth of the blooms.

From about the 6th to the 12th of November the best blooms were generally seen, the weather at that time being drier, consequently few blooms had been lost through the damping of the florets. During this period the National Exhibition was held, which I should think was the best yet held by the Society. The leading stands of incurved were very massive, yet many blooms lacked high finish. This was through no fault of the exhibitors, who had done their best, and done well, to combat the unfavourable weather influences. I do not consider that the best Japanese blooms were equal to those of last year in quality, speaking in a general way. Although some very fine examples were staged many were thin and showed a want of solidity and substance of the petals. But taking the whole exhibit of Japanese blooms I consider they were remarkably good when the unfavourable weather of the past summer is taken into consideration. With one exception I consider the blooms in both sections—the incurved especially—as staged in the northern counties a long way below those staged in the south in point of merit, owing to the fact that the north has not been so favourable as even the south this season for high class blooms. In very few exhibitions in the north could be seen a really good stand of incurved blooms. Roughness was very apparent and hollow centres numerous, and many “big” blooms lost points on close examination. I never saw blooms staged in the reflexed section in such poor condition as they have been this season. I cannot say that I have seen a first rate stand anywhere. There have been a few individual specimens that might be called good,

but the same stands contained faulty examples. This section especially seems to have seriously felt the adverse influences of the season. Especially were the blooms wanting in depth and closeness or firmness, also in colour, even Cullingfordi and King of Crimson being lacking in richness. I fear in the rage for after large fanciful varieties of Japanese the true reflexed section is liable to be somewhat neglected, as the blooms are less showy than the others named. Seldom do we see the plants this section placed in the best position out of doors, therefore cultivators have themselves a little to blame for the great falling off in the quality of the specimens.

Anemone flowers of both races have suffered also, but not to the same extent as the reflexed. I think the Japanese forms have not been favoured quite so much as have their older brethren the large-flowered Anemone so-called, some of the former lacking so much in the centre as to make it difficult to say whether they belonged to the Anemone section or to the ordinary Japanese. In point of colour there has been much falling off in the Anemone Japanese, also many “washy” blooms having been staged.

Pompons have been staged remarkably well at some shows, especially at the Aquarium, Portsmouth, and Brighton, the blooms being full, well coloured, and of large size. In fact, so large were some of them that it almost becomes a difficult matter to say where the Pompons leave off and the reflexed begin, so near do the former approach the latter in size and appearance. In the north this family has not as yet received much attention. At Liverpool they were especially poor both in quality and “setting up,” being placed much too low on the stands, not showing sufficient foliage, which enhances their appearance wonderfully. Anemone Pompons have not been so good in quality as the ordinary Pompon, the centres in many instances being but poorly developed. At only one Exhibition have I seen stands of fimbriated or single varieties—Portsmouth. It is a pity they are not more encouraged, especially the latter type, so light and graceful are they for the decoration of vases either alone or mixed with other flowers. If societies were to offer prizes for them more generally there would quickly be some shown, and the taste for this section would spread, much to the advantage of exhibitions and to those persons who grow only for home decoration. —E. MOLYNEUX.

CHRYSANTHEMUMS IN AMERICA.

WRITING on the cultivation of Chrysanthemums in America, Mr. John Thorpe remarks in the *American Garden*:—It is not saying too much to state that there are more than twice as many Chrysanthemums being grown this year than there were in 1887. Not less than a million of plants were sold by the florists of America last spring, and if there is no mistake in my calculation there will be still more sold another year. To those who, from prejudice or a commercial standpoint, have frequently said the past four years, “Well, this is the last year of the Chrysanthemum craze,” let me say that not until the Hyacinth and Tulip, the Hepatica and Violet are discarded or unwelcomed in the spring, will the Chrysanthemum be unpopular. For supplying the markets with cut flowers, as much attention is given Chrysanthemums by many growers as is given to the cultivation of the Rose.

A DISCUSSION ON THE CHRYSANTHEMUM.

At the December monthly meeting of the Sheffield Floral and Horticultural Society, a most interesting discussion took place upon the Chrysanthemum. Mr. W. K. Woodcock had originally promised to give a paper on “Some New Varieties of Chrysanthemums,” but having left the town he was unable to do so. However, a good substitute for Mr. Woodcock was found in Mr. John Farrow, gardener to F. Mappin, Esq., Birchlands, Ranmoor, to lead off the discussion.

Mr. FARROW hoped that the present arrangement would be both instructive and interesting, for no doubt many different ideas and practices would be exchanged. No one could deny that the Chrysanthemum is a most beautiful and interesting flower and well repays the cultivator for the trouble taken. There is no flower that has risen to such a high state of cultivation during the last ten or fifteen years. The Chrysanthemum supplies us with flowers of beauty and usefulness just at the time of the year when flowers are not very plentiful, in fact he did not know what we should do without them to meet the present demand for flowers. But how many failed to obtain high class blooms by certain small and simple errors. He had heard many individuals say, “Oh, the Chrysanthemum is easy enough to grow.” They were right to a certain extent, but how often do we see the same people when they try to obtain blooms of superior quality completely fail. He had found by experience that the Chrysanthemum required skill, carefulness, and judgment together with a large amount of study to grow it well; and those who wished to excel ought to be thoroughly acquainted with each variety, as some varieties require different treatment from others.

One of the first points of importance is the time of striking the cuttings, as this has a great influence on the bud taking, often causing some varieties to be late or much too early. It also causes the cutting in some cases to form flower buds instead of growth. He found the best time for inserting the cuttings in this locality to be from the last week in November to the first week in January for the production of high-class blooms. He rooted his cuttings in a cool frame with a little bottom heat, afterwards growing them on in cold frames protected from the frost, and when the weather permits placed them outside. The next point of importance is the final potting. He considered all

should be potted by the end of the first week in June, for if it be driven later it interferes with the ripening of the wood. The next important point is the soil for potting. He used three parts good pasture loam and one part leaf mould, with burnt ashes and charcoal. He did not like to pot in too rich a mixture, but to feed the plants as they required it during the season. He claimed that the advantages gained by this system were that he had a full acquaintance with their requirements, and was not so liable to make mistakes by overfeeding. The next consideration was potting the plants firmly. The soil must be rammed well and made firm, leaving it just so that the water will penetrate through. If not potted firm enough the wood will be unripe and unfit to build up the blooms, and imperfect blooms will be the result, as many have experienced this season. The next point of importance is watering. Some people imagine they cannot overwater the Chrysanthemum, but this is a great mistake. The Chrysanthemum requires plenty of water, but it should be given when needed. Great mistakes are made by letting the plants get dry, which causes checks in the growth, and blind flowers and disappointment often follow. With regard to the course to pursue in growing the plants for high-class blooms he believed in letting Nature take her own course with a few exceptions. He recommended striking the cuttings of early and late varieties at different times, believing that where time could be afforded it was a much superior plan to any other. How often did we hear it said, "I am afraid my so-and-so is too late or too early." He believed that, with certain exceptions over which we had no control, the Chrysanthemum could be had in bloom at any reasonable date.

The most important point of all is "taking" the bud. This requires great care, judgment and skill in it can only be gained by experience. If the buds are not retained at the right time for each variety it is useless to expect flowers of first-class quality. It is not the particular date on which the bud should be taken, but the state of each individual plant must be considered and the peculiarities of each variety thoroughly understood before success could be achieved. Japanese late varieties require their buds to be taken early; for instance, *Boule d'Or*, *Meg Merrilies*, *Grandiflorum*, *Golden Dragon*, and others about the middle of August. From his own observation and that of others he considered the best time to be generally from the 18th August to the 1st September, and if all other things were satisfactory he was sure success would follow. It was a mystery perhaps to some that when they took every care of a bud they found it did not swell and develop properly, and perhaps would not open. In his opinion this was caused by too strictly stopping the side growths, and thus, there being no course for the sap, the bud not being large enough to take it, a check to the plant follows, and the bud becomes useless. To remedy this evil he recommends that a growth or growths should be allowed to stay to take up the superfluous sap until the bud requires it.

Ripe wood is of great importance, for without it no high-class blooms can be expected. By the time the Chrysanthemums are in bloom the wood should be quite hard and brown, and the leaves should have a bronzy appearance. He had not seen many plants of this sort this season. The next and last point of importance was feeding the plants. There were many different systems of feeding and many kinds of manure employed. On this part of the subject he would say little, but let everyone follow the particular method he considered best. He believed from his own experience and that of others that the Chrysanthemum required feeding as soon as the roots were round the final pots, commencing with weak liquid and working up by degrees until the flowers are three parts open. He had proved this to be the best method by treating plants differently side by side.

Mr. H. BROOMHEAD thought he had found out a good deal this season. He was strongly against feeding the Chrysanthemum before the buds could be seen. The Chrysanthemum was not such a gormandiser as many people thought it was. He cautioned growers against putting their plants out too soon in May unless they had a very sheltered spot, because of the strong winds we had to contend with during that month. He preferred to put them out the first week in June. He also advocated getting them in early, and recommended all plants, whether early or late, to be housed by the 1st October. We were never safe from severe frosts after the beginning of October. With regard to setting the buds he thought it was not advisable to take every lateral away at first, but to do it by degrees, one or two now and then, and the grower would have better buds. He also recommended that weak varieties should be potted in smaller pots, leaving the soil rather looser; also that a lighter mixture should be used, consisting of half leaf mould and half turf pulled to pieces with the hand, riddled, and a shovelful of soft coke, about the size of peas, obtained from manufactories, and added to the compost. This would effectually prevent the soil becoming waterlogged, and the roots seemed to like these ashes and to cling to them. He also recommended syringing the plants the first week after the final potting instead of watering.

Mr. E. HOLLAND said that a failure generally brings success. He had failed this year in growing the Chrysanthemum, but he had found out where he had failed. His first failure was in the final potting. He had made the soil too solid before putting in his plant, and the result was the water would not pass through, and the roots refused to enter it. He had proved this by turning out a plant, and found that the roots had not worked in the bottom soil at all. He had also made his soil too rich. He had used turf, leaf mould, oyster shells, soot, and Beeson's manure. He found he had used too much soot, for when rain came the plants flagged and turned their tops down. He turned some out and repotted them, and they recovered. Mr. Holland asked the question whether in

taking the bud and stripping off the laterals would it be better to commence at the bottom or the top of the shoot?

Mr. BROOMHEAD replied that the top of the shoots should be first cleared, or you would lose the bud altogether if a crown bud.

Mr. HOLLAND said that with regard to feeding, if potted in fairly rich soil they would carry through with little or no feeding. He thought they required something in the soil to get them to form good buds.

Mr. FARROW bore out what Mr. Holland said in regard to too rich a compost. He knew a grower who made the same mistake, but finding it out he shook out all his plants and repotted them, and finally took prizes.

Mr. BROOMHEAD said one of the most important things is top-dressing. About the beginning of August many roots near the surface of the soil get bare, and the sun injures them. A barrowful of good material should be in readiness, and any time when looking over the plants a little can be sprinkled over the surface, and every watering will carry nourishment down and new roots will form and gradually work to the top, when they can be top-dressed like the others. He advocated for the top-dressings bone dust, leaf mould, and manure all rubbed together, but being careful not to ram it. This top-dressing will carry the plants on until the buds show, and then give them a little light liquid, clear and thin. He also recommended that in very hot weather the pots should be shaded by boards.

Mr. COLLIER considered that many mistakes were made by potting in too rich a compost. It induced a gross growth which at first delighted us, but in the end showed us that the plants could not get properly ripe. He was in favour of frequent top-dressings, as he considered they were the life of the plant. He top-dressed many kinds of plants with advantage. He did not advocate very early striking of the cuttings, but when a start was made it should be followed up and all checks to the plants avoided.

Mr. HOLLAND asked whether the Japanese required larger pots than the incurved?

Mr. BROOMHEAD considered a 9-inch pot was large enough for any plant. He used 8-inch, $8\frac{1}{2}$, and 9-inch pots, and none any larger.

A vote of thanks was given to Mr. Farrow and all who took part in the discussion, and this interesting meeting concluded.—E. D. S.

ON OVER-SUPPLY OF GARDENERS.

[By Mr. J. Barry. Read at a meeting of "The Chiswick Gardeners' Mutual Improvement Association."]

GARDENING has been, and still is, undergoing great changes in this country. What will be its ultimate position? This would seem to be an important question well worthy of consideration. They, the "younger members," form part of that rising generation of gardeners, who in the fulness of time will succeed those who are now so worthily maintaining the supremacy of British horticulture. One word of advice here. They must, to be successful, march with the times. The subject of this paper may, for convenience sake, be grouped under two general headings—viz., Emigration and Selection. The latter term may at present seem somewhat ambiguous, its full purport will be seen later on. I take it that few will dispute the truth of this proposition—viz., that there are too many gardeners. One may also be reminded that while the market seems to be overstocked, really good gardeners are more in demand and more appreciated now than ever in the history of horticulture. The bane of present-day gardeners is their anxiety to be employed under glass—as has been well said, the horticulture, commercially considered, of the future will be gardening in the fields. The present demand is for all-round men, and a man who can grow anything, from Grapes and Tomatoes to Strawberries, Mushrooms, and Orchids, not forgetting Potatoes and Cabbages, hardy flowers, and trees and shrubs, is as sure as fate to succeed if he is sober and industrious. It is not my object to decry cultivation under glass—by this method we are enabled to enjoy at home the luxuriant and beautiful vegetation of the tropics—but often all the beauty of English gardening is not in the indoor but in the outdoor arrangements.

I think we must go back to some twenty or twenty-five years ago, a time of prosperity by leaps and bounds, when gardeners were manufactured, to understand aright the present times. In those days there was plenty of money spent, and consequently there were foremen and journeymen in quantity in various gardens. As times began to get bad foremen were dispensed with, then fewer journeymen were kept. Then, perhaps, a cheaper head gardener was wanted, and many a foreman has taken a head place at considerably less wages than the head gardener who was leaving had been receiving. I know of good head gardeners who have been out of place for three or more years, and yet they have testimonials which should carry them anywhere. The struggle for bread and cheese induces some men to take situations at any wages, and the desire to save a few pounds a year induces employers to offer low wages, and they find they can get a man, calling himself a gardener, on their own terms. Whether he really is a gardener or not it takes time to find out, and meanwhile the saving a little on his wages is the consolation to the employer. The wage question is, I know, a very sore one, and I will only allude to it briefly. Underpaying head gardeners is a bad policy. The feeling entertained by a good man ill paid is a desire to leave the service, and an intention to do so the first opportunity that offers. Compare the wages of a groom or a butler with the wages of some gardeners, and you have the best possible comment that could be offered on the question, but so long as the supply is

beyond the demand, so long will wages be low. This is the grand secret, if secret it be, why gardeners in many instances are not better paid than the "powdered" gentlemen to be found "standing at ease," or awfully busy doing nothing, in so many of the establishments in this country.

It has been well indicated by Mr. Ruskin, and other eminent writers, that there is probably no nobler task for human enterprise in the present day than that which is to be found in the great pioneer work of colonisation—the leading forth of the surplus thousands of the Old World to people the vast solitudes of the New, and the removal, as far as possible, of the rude natural obstacles which lie in their path to the establishment of happy homes and civilised conditions, such as their more favoured or more fortunate fellow-countrymen enjoy at home. It is being more and more recognised that this is not a work in which only Colonial Governments can render effective service, but one in which the strong incentives to individual genius, energy, and enterprise which may be afforded to the private capitalist, and the best organising and pioneering abilities that can be induced to engage in it should not be wanting. One remedy for the congested state of affairs in the gardening labour market would appear to be emigration. I know it will be urged that gardening as a profession is not overstocked with really good men, and that England will never have a surplus of masters of gardening, or with men who are capable of system and economy in the management of land, such as Gilbert, Douglas, Wildsmith, Roberts, Bedford, Coleman, Simpson, the Thompsons, and many others. But to my question. I have lately had a conversation with a gentleman well known in the horticultural world, who has spent a good many years in our colonies. It is twenty years since he left the colonies. At that time he states there were a good many wealthy gentlemen who had extensive gardens that required special attention. With the rapid growth of wealth in them this number must have largely increased, and the demand for gardeners must have grown in proportion. As to wages, these are invariably high compared to the sums paid in England. As to the suitability of the English gardener for the Colonies, it depends so much on the man and his special knowledge, together with his willingness to work—the latter a most essential condition to success. Gardeners and their abilities vary. The landscape or pleasure gardener, the fruit grower, and the market gardener are each of a different class, but there is invariably room for the two latter while the demand for the former is limited. In this gentleman's colonial days a gardener who was a good all-round man did not mind looking after a horse, while his wife would handle the family cow, turn out a decent bit of butter, and tend the fowls—wages £100 a year, with house and rations; and if they had two or three children that did not matter much. These were not looked upon, as at home, as encumbrances! They were all found in plenty of food—this has reference to Australia. Sir Charles Dilke, in his able work "Greater Britain," says with time and care Australia ought to be the vineyard of the world, and our neighbour, Mr. D. Morris, the assistant-director of the Royal Gardens, Kew, has written: "From these sunny lands, where our sons and daughters have made their homes, we shall draw our future supply of fruit, in quality and quantity probably exceeding that of any fruit industry the world has seen."

Having so far disposed of one remedy, I proceed briefly to consider the second. The great want of the present day seems to be a national and comprehensive School of Horticulture, in which we could train really competent men; men who, in the fulness of time, will adorn and not disgrace the profession. This is indeed a large subject. I can only within the limits of such a paper as this touch the question. Such a school should issue certificates of competency, granted by well-known thoroughly qualified and practical men to the candidates, and if employers really had at heart the best interests of horticulture they would only engage for their service such men as have passed successfully through the trying ordeal. The certificate from the National School of Horticulture should be the hall mark of merit; the "badge of honour" by which every gardener should be recognised and respected. This would indeed be carrying out the Darwinian maxim of the survival of the fittest. Perhaps a great—the great evil—of one of our present courses of procedure is the apprentice system (at best a bad system), particularly as it affects those serving short terms. At the end of the brief period of their apprenticeship, by the influence of their master, they obtain a situation in some garden, where, thoroughly ignorant of the very rudiments of their trade, they are a disgrace to themselves and often an annoyance to others, besides occupying the room of somebody who has obtained a good knowledge of his business, and through the avarice of some individual is supplanted by an ignoramus who can dig, rake, and hoe, and there his abilities stop.

Perhaps I have drawn a somewhat gloomy picture of the gardener's position in this country. There is, however, one bright speck in the horticultural sky; may it grow larger and larger, and illumine by its welcome radiance the heart of many a struggling blue apron. Fruit culture, gardening in the fields in this country, is coming to the front. With a reform in our land laws there is indeed a bright ray of hope for the gardener here. No doubt in the good time coming there will be a considerable extension of both fruit growing and market gardening in many parts of the country, which will create much employment for the cultivators of the soil. To sum up—there is evolution in horticulture as in all other things, and the gardener must change with the times, or give up his gardening and try something else. He must fit himself and do his best to meet the wishes of his employer, even to the sacrifice of a few of his own ideas and notions. Success in life, so far as a gentleman's gardener is concerned, is as much due to his ability in a social

sense as to his skill in land culture, or in plant or fruit-growing. There is nowadays a growing desire to make land—gardens included—more profitable; and a new race of gardeners who will devote themselves to the solving of this problem will be bound to succeed. Some people say fruit culture will do it, but the same result will be gained in different ways in different places, and to find out some way of making land profitable is well within the gardener's province. His capital and skill may either be focussed under glass, or it may be more widely spread over a garden farm, but it is the gardener's business to do his best towards making his native land fruitful and profitable.

ASTER COMET.

DURING the present year we have seen several remarkably fine examples of this distinct and beautiful Aster, and we were much impressed with a stand of blooms at one of the autumn exhibitions. It has been

FIG. 67.—ASTER COMET.

aptly compared to a Japanese Chrysanthemum with long flat florets slightly curling at the tips, but in colouring it is quite unique, white striped with bright pink, the latter colour being principally confined to the margins of the florets, somewhat in the style of Belle Paule Japanese Chrysanthemum. The illustration (fig. 67), for which we are indebted to Messrs. Sutton & Sons of Reading, appears in the issue of the above firm's "Amateurs' Guide in Horticulture" for 1889, an elegant and useful production, showing this year a still further improvement on previous efforts. The Aster as represented is tall but compact in habit, with large blooms terminating nearly every shoot.

CIDER.

A CORRESPONDENT writing from Suffolk asks whether cider is an old drink or not, and if we can tell him how long it has been in regular consumption, adding that it is not made and seldom seen in the eastern counties. In searching for information on the subject we came across the following notes on "Cider and Cider Orchards in the Olden Time," which may, perhaps, interest others besides our East Anglian inquirer:—

Cider is now grown, to use a common expression, in great quantities in what is known as the cider country or cider counties. There the great part of the population drink nothing else. Devonshire,

parts of Somersetshire, Worcestershire, and Herefordshire are pre-eminently cider counties.

The early use of a drink called cider, and the production of such immense quantities of that beverage, such as that of 10,000 hogsheads in one parish—viz., Martock in Somersetshire—are two distinct matters.

Cider, without doubt, is of early origin, and is supposed to have been first known in Africa, as it is mentioned by Tertullian and Augustine, the two fathers. St. Jerome speaks of an inebriating liquor made of the juice of Apples.

Biscay, long famed for its cider, received it, as is believed, from the Carthaginians. A full description of this beverage is given by Navagerus, in the journal of his embassy to the Emperor Charles V.

The ancient Britons, like other northern nations, may have made an intoxicating liquor from the Sorbus, or Service Tree; and though hardly from the indigenous Crab Apple, yet some perhaps from the better kind of Apples introduced by the Romans. The Anglo-Saxons distinguished their "Eppelwin" from wine and mead.

The Normans probably obtained their cider Apple trees from Biscay; the climate and soil there both favoured their growth. To the abbeys of that country we must look for the improvement of Apples and cider-making.

Near Valognes, in the Department of La Manche, stood the famous abbey of Montebourg. The possessions of this abbey extended to Dorset and Devon. Besides lands in Axmouth parish in south-east Devon, the manor and church given in the reign of Henry II., there were also other lands, and a priory in Loders, near Bridport, Dorsetshire.

Cider was made on the Montebourg lands before the year 1286. The monks, who possessed nearly all the knowledge that prevailed at that era, had introduced upon their estates on this side the Channel Apple trees, for the growth of Apples for cider-making. They had also taught their tenants how to make cider according to the approved plan of Normandy, which is still preserved in that part of France, in the Norman islands of Guernsey and Jersey, and in Herefordshire.

W. Villata, of Loders and Bothenhampton, near Bridport, held land of the Abbot of Montebourg upon payment of 6s. a-year, and upon his finding a horse (*ad molendum poma*, &c.), to grind the Apples in what is now called a horse-mill.

The skilful monks may have done much towards the improvement of their estates by the introduction of better fruit trees. Probably others were not disposed to adopt novelties any more than their descendants in the present day.

The Quarantine Apple is supposed to be a corruption of Carentan Apple. Many other names are old names corrupted in the course of years. A periwinkle shell-fish is termed a *gobbet*. It is the Norman *gobet*, a mouthful, as the famous Cherries of the valley of Montmorency are now called *les bons gobets*.

That cider was made, as before related, in the twelfth century cannot be denied; but not to any great extent, if we institute a comparison with the great doings nowadays of cider-making Devon and Somerset.

The Vicar of Dawlish, in the South Hams (now a watering place), received, in 1280, one-half the crop of Apples, doubtless grown for making cider.

The word Orchard, or, as it is now pronounced, Orchat, perhaps a name given by the monks from *Orchatos*, has been a fruitful source of error. It was not in any sense the orchard of modern times. The latter is a space planted with Apple trees of greater or less extent, unlike the practice of Normandy and Brittany, where pasture and arable land are crossed by rows of Apple trees, and where the English practice of planting the trees in one spot with grass under them does not obtain.

The orchard of early reigns was a place laid out with trees, as a pleasure garden for walking, recreation, and sports, having arbours, and similar appropriate places. Such a spot, if Apple trees prevailed, was called an Apple garden or Apple orchard.

An Apple garden is spoken of in "Domesday Book" as existing at Nottingham. Horti and Hortuli are frequent in the same record.

The monks of Lewes Priory, Sussex, had in their enclosure of thirty-two acres and a half within walls a paradise (park), a garden, and an Apple orchard, which felt the effects of a gale, A.D. 1267.

There were ardent lovers of horticulture among the clergy. Upon the extension of a part of Wells Cathedral about the year 1326, there was a special provision made for the careful preservation of a certain Medlar tree. Quinces sold in 1292 at 4s. the 100.

Wycliffe knew of the strength of cider, for he translated the passage, Luke i. 15, "He shal be gret biforn the Lord, and he schal not drynke wyne ne sider."

One Cottingham, of Seaford, gave a bond, 26th Elizabeth, that

while he should continue a tippler he and his household should be orderly, and keep no unlawful games or evil rule within his house, garden, or orchards during the said time of his tippling—i.e., dealing in liquor. In the orchard was doubtless the skittle-alley for summer days.

Butler, in his "Hudibras," gives among other acquirements of Sidrophel that he knew—

"And in what sign b.s.' sider's made."

So that in the reign of Charles II., not only was attention paid to the growth of the Apple, but to the making of this fruit into cider—an operation of importance enough to be referred to an astrologer, then a common practice.

Apple trees and Pear trees also began to be much cultivated about the middle of the seventeenth century. In a pamphlet addressed to the well-known Samuel Hartlib, Esq., A.D. 1657, entitled "Herefordshire Orchards, a Pattern for all England," it is asserted that Gennet-moyles bear every other year, and make the best cider. Mordicant, or sharp cider, pleased the peasant or working man, as was the case in France.

In Herefordshire few cottagers, and even few of the wealthiest yeomen, taste any other drink in the family but cider, except at some special festivals twice or thrice in a year, and that for variety rather than for choice.

The credit of cider had of late years much advanced in the estimation of the best gentry, who had sought out the right method of ripening and hoarding the choicest fruits, and some also of bottling it.

"But I am confident," the writer adds, "that much more may be added to the perfection of it, when they shall also apply to it the due subtleties of the mysterious art of fermentation."

Each cultivator bestowed greater attention, having proved that—

"Else false hopes
He cherishes, nor will his fruit expect
Th' autumnal season but in summer's pride,
When other orchards smile abortive fail."

PHILIPS, *Cider*, Book i.

Wassailing the orchards on New Year's Eve is called in Sussex and those parts "Apple Howling" from the words used:—

"Stand fast, root; bear well, top;
Pray the God send us a good howling crop," &c.

Hence the entries in former centuries of money given to the "howling boys" may be understood.

Hooker, in his MS. survey, records that the Apple was cultivated in Devonshire so early as 1520. He must mean begun to be grown for the purposes of cider. He continues, "but in the beginning of the following century it received more attention."

So long as the narrow lanes served to keep up the communication between the principal towns, and pack-horses did all the work, there being no carts, how could cider in hogsheads have been sent about the country? It could not have been sent to any great distance.

The absence of the mention of cider up to a certain period in borough archives is very remarkable. In accounts, where every halfpenny is carefully set down; in dinners of the most homely kind, and feasts, such as the Cobb Ale at Lyme, and the feast at Ford House; in a dinner to Charles I., altogether (for the country) very sumptuous up to this period referred to, and which required to be specified, there is no mention of cider; then cider takes its place with ale and beer, and furnishes an item in every account for refreshment or festive enjoyment at table of the inhabitants of boroughs.

In the detailed presentments of the Hustings' Book for Lyme for the year 1597, of the stealers of wood and pollers of trees for fuel, appears this entry:—

Item, they present George Browne's son, Hoode's son, and Thomas Sampford's boy to break into men's orchards and steal Apples.

Whether these were Apples for the table or for cider matters little after what has been written above, as no cider is mentioned in the archives for 110 years.

In 1629, Apples were cultivated in Massachusetts from seed imported from England by order of the Governor and Company of the colony. Governor's Island, in Boston harbour, was given to Governor Winthrop in 1632 on condition that he should plant an orchard upon it.

A hogshead of Somersetshire cider was brought to Mr. Richards, near Dorchester, A.D. 1699, upon the occasion of England and Scotland being united into one kingdom; a hogshead of cider was given by the Corporation of Lyme to the soldiers at a cost of 25s.

Wine, beer, and cider were given away at Minchinhampton upon the accession of King George in 1714.

In 1745-6 the accout of Robert Henley, Esq., Mayor of Lyme, exhibits:—

April 28. Two hogsheads of cider supplied to the populace on the association (to support his Majesty George II.), and on the victory obtained over the rebels, £2.

The Mayor purchased this cider at Pinney Farm, of Walter Oke, a country gentleman who farmed his own land, and had planted some of the now far-famed Clevecland, late Pinney-under-Cliff, with Apple trees.

The farmers of the Somersetshire parishes near Sedgemoor, so soon as they heard that the king's forces had won the battle and defeated the Monmouth men, sent hogsheads of cider to the victors. The price of a hogshead of cider given away at Axminster in 1689 was 17s. 6d.

The excellence of the cider made throughout the breadth of the cider-growing west is very great; the quantity is enormous. Some localities which have a good name for their cider send out much more cider than is produced therein, like in wine countries, so much does man resemble man in all countries and ages. The growers in the localities in question buy Norman Apples at a cheap rate and mix them with their own fruit.

Some gentlemen, travelling from Strasbourg to Freyburg, stopped at the village of Altenheim, in Baden, at an inn kept by a respectable man who farmed his own estate of 100 acres. Perceiving how loaded the trees of this orchard were, the English gentlemen spoke of the great crop of Apples and of cider. The German informed them that no cider was made in that country; the juice was mixed with the juice of Grapes and made into wine!—(*Roberts's Social History of the Southern Counties.*)

FRUIT CULTURE IN CALIFORNIA.

(Continued from page 569.)

WHILE Europe, Asia, and some of the United States can grow one or two of their fruits, there is no spot on the globe where they can all be grown to such perfection as in California. It has been demonstrated both by theory and practice that the demand for our fruit products can never be fully met; that the market will never be so fully supplied as to render the prices unremunerative to the producer. With the large acreage of fruit trees now in bearing the entire product is consumed by a very small fraction of the population of the United States. Practically the supply is exhausted before it gets further east than the Mississippi. Last winter more than 2000 eastern people visited the rooms of the Board of Trade in San Jose. They represented every State in the Union, and of the entire number not one had ever seen a dried Apricot, one of the most luscious and healthful fruits that the earth produces. The Apricot crop for 1887 was probably double that of any previous year. Hundreds of acres of new orchard came into bearing, and the trees were loaded. Notwithstanding the enormous yield, prices were firm and exceedingly remunerative, netting the producer from 200 to 450 dollars per acre, while hundreds of eastern orders could not be filled. It has been estimated that all the Apricots raised in California would not furnish a saucerful each to the inhabitants of New York City. The variety of fruit that can be grown in Santa Cruz is infinite. Every plant that has been put into the soil and given reasonable care has thrived wonderfully and yielded abundantly. We have space but for a partial list.

ORANGES AND LEMONS.—From the time the Catholic Fathers established their Mission at Santa Clara (more than a hundred years ago) it was demonstrated that Citrus fruits could be grown to advantage in this section. Orange trees were planted then, and have been planted since in almost every part of the county. The trees were grown more for ornament and family use than to supply a market, and no considerable groves were planted until about six years ago. The success attending these later plantings show that, if desirable, Santa Clara County could achieve as great a reputation for her Oranges as is enjoyed by Florida, Los Angeles, or the countries of the Mediterranean. At the Citrus fair, held in San Jose last winter, magnificent specimens of Oranges, Lemons, Limes, &c., were exhibited from 183 different localities in the county, and all were grown without irrigation. But while the yield of these fruits is large, it is not considered so safe or so profitable an industry as the growing of other varieties. Oranges must be marketed in a fresh state, and must come in competition with similar fruit from Florida and foreign countries. Freight rates on such articles are necessarily high, the risk of loss great, and the market temporary. Other fruits can be cured, and thus rendered as imperishable as Wheat or flour. They can be transported at leisure and can be put on the market at any time that the price suits the producer. The labour and expense of production is much less, while the profit is considerably greater than in Orange culture. It is for these reasons the fruit-growers of Santa Clara County have not gone extensively into the cultivation of Oranges, and not because we cannot grow them to perfection. To put it in a short form: There is not so much money in Oranges as in other fruits.

FRENCH PRUNES.—All varieties of Prunes yield immense crops here. Of the eighty varieties grown for market experience has taught us that the French Prune is the most profitable. It is planted 108 trees to the

acre, and yields a good crop in four years. Trees from six years old upwards give about 10 tons, or twenty thousand pounds, to the acre. The price ranges from a cent. and a half to two cents and a half per pound for the green fruit, making an average yield of from 300 to 500 dollars per acre. Twenty to twenty-five dollars per acre per year will pay all the expenses of the crop. If the fruit is cured before being marketed the profits are much larger. There is less labour and expense in growing the French Prune than any other fruit. While the cultivation of the soil is about the same the labour of pruning is considerably less, and of harvesting and curing not more than 10 per cent. that of other varieties. It has been estimated that the French Prune can be cured ready for market with as little labour as it can be hauled a distance of two miles. The Prunes grown in Santa Clara County are large, heavy in sugar, of exquisite flavour, and make a healthful food. Their merits have become known in the fruit markets of the east, and the demand is far ahead of the supply.

APRICOTS.—This delicious fruit finds its congenial home in Santa Clara County. It is a fruit that was comparatively little known until California horticulturists introduced it to this coast. Here the fruit of our best varieties measures from 6 to 9 inches in circumference, and is of such a delicate flavour that once tasted it is never forgotten. It is largely grown in this county and with great profit. The trees are planted 20 feet apart, giving about 108 to the acre. It yields a considerable crop the third year, which increases indefinitely as the trees become older. Some thirty-year-old trees in this county have borne 1800 lbs. of fruit to the tree. Five-year-old trees this year have given 200 lbs. of merchantable fruit, and have netted to the owner 3 dollars and upward per tree. Where the fruit has been cured the income has been much larger, reaching in many instances as high as 550 dollars per acre. In this fruit we have no competitors. No other country can grow Apricots in quantities sufficient to make any impression on the market.

CHERRIES.—This favourite fruit yields its best returns in this county, and our claim to the market is based on the fact that we can grow it to greater perfection than elsewhere, and get it to the eastern markets in advance of all other fruits. While it takes longer for a Cherry tree to come into full bearing than it does for Prunes or Apricots, the returns will amply compensate for the delay. The range in prices is from six to eight cents per pound, and the returns at these figures almost surpass belief. In a good season many of the older trees yield from 400 to 600 lbs. each, giving a return of from 1200 to 2000 dollars per acre. These, of course, are exceptional figures, but a safe average estimate would give us from 400 to 600 dollars per acre. That these are not fancy estimates is shown by the following incident:—When the San Jose and Almaden railroad was projected the route was surveyed through an orchard, and it was found necessary to remove a Cherry tree. After an impartial trial on the question of damages it was estimated that this tree was worth 600 dollars, and that amount was paid by the railroad company to the owner for the privilege of removing it. The decision was made on the ground that the tree had for a number of years yielded an annual net income equal to 10 per cent. of 600 dollars.

PEACHES.—Of this standard fruit Santa Clara County produces all the favourite varieties grown in the East, together with many new kinds which have been originated here. Unlike its relatives in the Eastern States, which, owing to cold winters and other causes, are short lived, having to be renewed, on an average, every four or five years, the Peach tree here attains an old age full of vigour. There are many trees in the county over thirty years old which have grown full crops nearly every season since they were three years old, and which last year made a growth of wood 11 feet in length. The trees come into bearing in three years from planting, while considerable crops at two years old is not an unusual occurrence. The capacity of a Peach tree for bearing is only limited by its strength to hold up the weight. Each year many trees which have been carelessly pruned break down under their loads of fruit, while props have to be used in almost every orchard. The largest and best California Peaches found in Eastern markets, were grown in Santa Clara County. The profits from a Peach orchard are about the same as from Apricots. We have known of over 700 dollars to the acre being realised, but the average return is less. A good orchard of approved varieties will average about 300 dollars net per acre. The present season (1887), although there was an enormous crop, the fruit is in great demand at from three to three and a half cents per lb., being about 6 dollars per tree for six-year-old trees, or something more than 600 dollars per acre, and buyers are, at this writing, scouring the country for the fruit at these prices.

PEARS.—This was the first California fruit to make its way across the continent and astonish Eastern people by its size, beauty and flavour. All of the choice varieties of the world have been transplanted to the orchards of the Santa Clara Valley, while our enterprising horticulturists have originated as many more. Many of the best Pears now in the market were first grown here, and several of them have been taken East and transplanted into orchards there. The fruit as grown here is particularly adapted to shipment. Being grown on vigorous trees, in a fertile soil, and in a climate free from moisture, they will keep in good condition and retain their flavour for several months. Pears from Santa Clara County stood on the table at the New Orleans Exposition during the entire Exhibition, without having to be renewed. Trees begin to bear at from three to four years from planting, but do not bear large crops until six or seven years old. The profit from them is about the same as from other fruits.

OLIVES.—This wonderful fruit, which is both bread and meat to the

people of certain countries, and which is yearly becoming more prized by the people of the whole world, deserves more than a passing mention. The more so, since the oldest and largest Olive orchard, outside of those planted by the Mission Fathers, is located in Santa Clara County.

(To be continued.)

ECONOMIC ENTOMOLOGY.

[Presidential address to the Highbury Microscopical Society, by Mr. James A. Forster.]

(Concluded from page 525.)

THE aphid is one of the main causes of Apples falling immature from the trees, and also largely affects the quality of the cider in certain seasons. This species is found all over the world. The Americans, however, claim that the pest was introduced in their orchards by trees brought from Europe. Another species very injurious to orchards is known as the woolly aphid, or American blight (*Schizonema lanigera*). Everyone who has closely noticed Apple trees will have frequently remarked knots or bunches of a downy or woolly substance on parts of the stems and in interstices of the bark. This is very frequently supposed to be a form of mildew, but if closely examined it will be found that this woolly substance covers little groups of aphides, all actively engaged in extracting the sap. This form is specially liable to attack newly pruned trees if the cutting has been done carelessly. Old and neglected orchards, of which there are too many, are the special home of this pest, the lichenous and moss-covered stems exactly sniting it and enabling it to remain unsuspected, while the trees attacked become after a time covered with swellings, checking leaf and blossom, and ultimately causing both stem and twigs to decay. This state is frequently called canker, and is attributed to any cause but the right one—the exhaustion brought about by the persistent suckings of myriads of larvæ.

I have dwelt much longer than I intended on the aphid; but before I pass on to other of our insect troubles, I must say a word or two about the phylloxera (*P. vastatrix*), which, although not occurring in this country, has produced such wholesale destruction in the French vineyards, that its name has become known throughout the claret-drinking world. The phylloxera is a species of aphid of very small size, and somewhat different in form from the species known in this country. It first appeared in France about the year 1863 or 1864, and is supposed to have been brought from America. It attacked first the Gard district; then rapidly spread to the south and west. Its minute size renders it almost indistinguishable without a glass, and its appearance is like a little powder adhering to the stem of the Vine. It is oval in form, is furnished with two vigorous antennæ, and has an articulated beak more than half the length of its body. This, when not in use, is folded against the lower side of the thorax, where it lies between the six little legs. Its body tapers somewhat towards the extremity. Their changes and metamorphoses are very similar to those already described. Towards the twentieth day of their life, on their attaining the adult stage, the abdomen enlarges on the sides, and four mamelons appear, and immediately after the insect lays a batch of eggs. Each female lays about thirty eggs in each batch, and as there are eight generations each year, the six months between April and November suffice to produce such a horde of the voracious creatures that more than half the vineyards of France have been destroyed by them. And even supposing means be found to extirpate them, it will require ten years for the mischief to be made good and the vineyards restored.

The evil caused to the Vine by the phylloxera is a complete draining of the sap from the stems. They attack only the main stems, which furnish them most abundantly with the nourishment they require. In spite of the attack of these countless living pumps, which work incessantly, the Vine stems continue a most rapid growth, more so than if in their normal and healthy state; but they become yellow instead of white, then gradually pass to brown, the shrivelled bark serving as a lair for the phylloxera. As the evil continues, the bark becomes more and more folded and shrivelled, until at last it assumes a blackish tint and falls in a state of decay. The insects then abandon it to make fresh attacks on fresh Vines. Failing fresh plants, they attack the principal roots, destroying their outer coverings after penetrating well below the bark. When one root is annihilated, they work underground to another, occasionally coming on to the surface of the ground to hunt for healthy Vines.

If not easy of detection in the commencement, the phylloxera cannot be overlooked after a time. After a vineyard has been infested for two or three years, the stems attacked underground produce only a leaf here and there. These are small and malformed, and after languishing for a time turn yellow and roll up. The whole plant dwindles, the Grapes, arrested in their development, hardly form, the pips split up, all fructification disappears, the leaves get thinner and smaller than ever, and soon the vineyard presents the aspect of complete ruin. And ruin it is, for the only cure is the thorough burning of the old Vines.

Many remedies have been suggested, but I do not think any have been attended with much success. M. Dumas proposed the employment of a concentrated alkaline solution of sulphate of potassium, or soda, and the ammoniacal sulphate produced in gas works. It is believed that this, if carefully used, would be efficacious, as the phylloxera would be poisoned and the Vines probably much benefited and strengthened by this chemical manure, but one important difficulty arose—viz., the question of expense, which is prohibitory.

Monsieur Bazille of Montpellier is stated to have employed with success a dressing composed of cow's urine, an alkaline sulphate, and one tenth of oil or tar. I, however, think the true and practicable preventive for the attacks of the phylloxera has yet to be discovered, and considering the immense interests at stake, such a discovery would be well worth making, and the discoverer would deserve well of France and the world.

The chief natural enemies of the aphid family are found among the beetles (Coleoptera), one family of which, the lady birds (Coccinellidæ), are the great destroyers of aphides, on which these beetles, both in their larval and perfect states, feed with the utmost voracity, and no better precaution can be taken against the attacks of "blight" than the colonisation of lady birds in our gardens. Another most valuable insect ally for this purpose is the common gauze-wing fly, sometimes called the "stink fly" (*Chrysopa perla*). It is well known in gardens, is delicate green in colour, has a long, thin body, four very delicate wings, and two exceedingly bright golden eyes. When handled it imparts to the fingers a most disgusting scent; hence its name of Stink fly. This fly in the perfect state preys on the aphid, hovering over the infested plants, alighting from time to time to snatch up some of its living food; but it is in the larval state that it does the most execution.

Among beetles we have many enemies, notably among whom may be mentioned the skipjacks (Elateridæ), known in their larval condition as wireworms; the May bugs and their allies (Melolonthidæ); the weevils (Curculionidæ), attacking corn, &c., in store; the corn beetle (*Trogosita Mauritanica*); the mealworm, another of the same family; the pea beetles (Bruchidæ); the pea weevils (Sitonidæ); the wood-boring Hylesinidæ, of which the *Scolytus destructor*, too well known in our parks, is a good example; the family of Longicornes, deadly enemies of forest trees; and the Chrysomelidæ or golden apple beetles. It is evident the limits of this paper would not permit me to give a life history of each of these destroyers. They are, with a host of others I have not enumerated, formidable destroyers, largely and directly affecting the profits of the farmer, though very frequently he has no idea of the cause of the failure of his crop, perhaps does not even know of the existence of the tiny ravager who has robbed him of the fruit of his toil. Take, for instance, the wireworm. This (*Agriotes lineatus*), in its perfect state, is a narrow brown beetle about two-fifths of an inch long, with long wing cases or elytra covered with parallel lines. They present somewhat a flattened appearance, and the thorax is produced into spines at the hinder angles, and underneath the breast plate is produced into a long point. They are remarkable for their great power, when placed on their back, of jumping or throwing themselves into the air by means of a sudden jerk of the thorax, in effecting which the thoracic prolongations come into their places with a sharp sound like the shutting of a spring. Hence their popular name of click beetles or skipjacks. In the perfect state it is probable the beetle does little or no harm to the crops, but in the larval stage it is most formidable. The larva is something like the mealworm, but more slender and elongated; it is yellow and exceedingly tough, like wire, whence its familiar name of wireworm. They have, I believe, no eyes, but possess a short, four-jointed antennæ, and are furnished with short robust legs set close together. The apical segment, possessing an anal prolongation, is especially hard and frequently toothed; they are found everywhere at the roots of plants.

The attacks of wireworms are most serious to Sainfoin and Clover crops, also to pasture lands, the finer grasses being invariably chosen, and the frequent failure of the grass seeds results probably more often from the work of the wireworm than from any other cause. It is throughout the United Kingdom a continual source of harm and loss to every description of corn crops. The wireworms fix their heads into the soft part of the stems, and with their hard, strong jaws gnaw away the tissues so as to entirely arrest the circulation of the sap. The insect remains in the larval state for several years (the limit generally accorded is five years), but it is difficult to ascertain the exact period. It is this long larval stage that causes them to be specially dangerous to those crops, such as Sainfoin, that remain on the land two or three years. When full grown the larva descends deep into the earth to undergo its transformation. It remains for a fortnight in the pupa condition, when the perfect insect emerges and comes to the surface of the ground. Fortunately this pest may be got rid of. A field that is infested with it should be thoroughly and deeply ploughed and scarified, and all growth in the soil rigidly destroyed. It should then lie fallow for a winter, and in the spring again carefully gone over to stop all weed growth, then be sown with tares. After this a crop of Mustard should be put in, and the wireworm will be effectually starved out, for numerous experiments have proved that it cannot eat either of these plants.

Other classes of insect enemies are the Cecidomyidæ or midges, of which the little Wheat midge may be seen at most seasons flying in swarms on the edge of Wheat fields. These later on deposit their eggs within the Wheat ears. The eggs soon hatch out little white maggots, which then bury themselves into the stigmata of the flowers of the Wheat plant, thus hindering the development of the grain, and frequently reducing the crop by a fifth or more. In some years the amount of destruction occasioned by it is very great.

Another most mischievous insect and very troublesome to get rid of is the well-known daisy-longlegs (*Tipula oleracea*). The female fly is stated by Curtis to contain some 300 eggs, forming a mass which fills nearly the whole of the abdomen. These she deposits in the autumn on

the grass, they hatch out in the early spring, and burying themselves into the ground soon grow into dirty-looking grubs an inch long, having very tough skins. They are destitute of legs, but still have the power of burrowing rapidly in the ground. They make their burrows a little below the surface of the ground and among the roots of the grass on which they feed. So actively do they work and feed that they quickly kill off a patch of grass, and their presence underground is then made known by an ugly brown dead patch on lawn or field. The best remedies we can avail ourselves of against these pests are the birds, especially rooks and starlings, and also the much-slandered moles, which, as devourers of grubs of all sorts, wireworms, &c., are simply invaluable, and should be cherished instead of being killed and trapped as noxious vermin.

The injury we suffer from the caterpillars of moths and butterflies is probably much better known than that caused by other classes of insects; still, the ignorance of gardeners and cultivators regarding these creatures, which are comparatively so easy of observation, is astounding. Among the lesser known, but not the less dangerous on that account, are the caterpillars feeding in the interior of the stems of various plants and shrubs; one of these, the clearwing moth larva, will serve as an example. The moth is small, having more the appearance of a fly than a moth, its wings being almost destitute of scales; it lays its eggs on the bark of Currant bushes. The larva on emerging from the egg immediately eats into the middle of the stem and then continues eating its way along the pith, always working upwards. It goes on feeding the whole of the autumn and a good portion of the winter, and emerges as a moth the next summer. When a bush is attacked by this creature nothing can save it, and the only thing to be done is at once to cut away right down to the ground all the doubtful stems, and carefully burn them. This should be done in the winter.

I have now touched in the most superficial manner upon four only out of the thirteen orders of insects, but I have more than exhausted my space and I fear my readers' patience. If, however, any remarks of mine shall induce anyone to study and observe the lives of these creatures that are competing with us for our food, I feel sure I shall have done some good. The field of research into the lives and habits of insects is open to all, and the knowledge to be gained is probably of far more importance to the world and likely to result in more direct gain to mankind than most of us dream of.

HARDY FRUIT GARDEN.

SEASONABLE WORK.—In most large gardens much of the pruning has already been done, and those in charge of smaller places ought also to push forward this important work much earlier than they often do. When the bushes and trees in the open are pruned early this admits of the manuring and surface digging being also completed before the men are required for other work. Many of the wall trees, in fact all but Peaches, Nectarines, and Figs, may also be pruned, and the nailing or tying attended to while the weather is favourable. Trees that are of vigorous habit and not very fruitful require no manure, but directly they arrive at a free-bearing state they ought to receive some assistance the better to maintain their fertility. Much-starved and stunted trees, these invariably attempting to produce heavy crops annually, absolutely require liberal treatment at the roots, otherwise they are unprofitable. Nor should Currants, Gooseberries, and Raspberries be neglected, these when of good size well repaying for mulchings or top-dressings of manure every year, or at least every second season. Nothing suits fruit trees generally better than a liberal dressing of partially decayed vegetable matter, such as a mixture of leaves, garden refuse, stable manure, and the contents of a "smother," or the heap of ashes and charred substances resulting from the slow burning of a great mass of rubbish and soil. Where leaves and manure are collected every winter, in the first place to afford bottom heat for forcing vegetables, and subsequently for growing Vegetable Marrows and ridge Cucumbers, this will be in admirable condition for present use. The ground about fruit trees and bushes ought never to be deeply dug, nor should spades be used near them. No harm will result from lightly skimming the surface with forks, the manure or top-dressing being turned in at the same time. In many instances it is advisable to just bare the topmost roots of choice fruit trees to a distance of not less than 4 feet from the stems; and after a liberal top-dressing has been given to surface this over with the soil thrown back. This is preferable to either digging-in the top-dressing or leaving it exposed, and the roots soon take possession of it, a marked improvement in the quality and weight of the crops being the sure consequence.

PEARS.—These amongst wall trees are usually the first to be pruned and re-nailed or otherwise secured to the walls. In the case of well established trees the operation is very simple. All that is necessary is to thin out the spurs where at all thick, the longest and those not well

furnished with fruit buds being selected for removal. These should be cut cleanly either with a pruning saw or sharp knife, and to within an inch of the main stems. Many of the old and ugly spurs thus treated will form fresh growths, and in time a cluster of fruiting spurs will be formed nearly close to the stems, or where they will get the full benefit of the shelter and heat afforded by the walls. Young shoots on fairly close and good fruiting spurs, whether they were shortened in the summer or not, ought now to be pruned, not being left much more than 1 inch in length. Occasionally branches about 5 inches in length with a fruit bud at the point will be met with, and these may be preserved, especially if there are but few fruit buds discernible on the trees. These can be duly shortened next autumn or winter, or after their retention is of no further use, but rather a disfigurement. It is very unwise to crowd the main branches, and where they are less than 12 inches apart (and it is no uncommon thing to see them not more than 8 inches apart) they ought to be considerably reduced in number, and the regulated so as to arrange them nearer 15 inches apart. The larger leaved varieties especially pay well for a little extra space being given them.

YOUNG PEAR TREES.—Where more wall or trellis space remains to be furnished by espalier or horizontally trained trees, the leading branch of this should be shortened to a length of about 15 inches, this being required to provide another leader and two more side branches for laying in. It is not advisable to shorten the leader or any of the side branches till such time as their limit is reached, the only exception being where the second or summer shoot that some of them form is unripe, and which should be shortened to the well ripened portion. When strong leading shoots are shortened, however slightly, only the buds near the point can be depended upon to break, and then only wood is formed, whereas those well-ripened growths not pruned will usually break at every joint, not unfrequently forming a series of fruit buds. This fact should not be lost sight of by those who are commencing to train Pears on what is known as the cordon system. Whether the cordon-trained trees are confined to one stem, or better still, are furnished with from three to six main branches, the treatment is much the same, and is extremely simple. Allow the well-ripened leading shoots to extend as rapidly as possible, and if not unduly pruned, fruitfulness soon results. Quite young lateral growths should be well shortened back, and in time abundance of good fruiting spurs will result. The stems and main branches of healthy young Pear trees swell considerably in one season, and unless the various ligatures used in training and securing them are closely looked to, injury may and very often does accrue to the bark. The latter ought never to come into contact with nails especially or other hard substances, or it is almost certain to be injured either by friction or pressure, while quite a soft shred will nearly cut through a stem unless removed in time. The shreds or ties ought not to be very tight in the first instance, and should be removed directly it is seen they are likely soon to unduly prevent expansion. Broad leather or stout "trousing cords" are the best for heavy Pear trees, ordinary cloth shreds being of little avail for other than young wood. When wire trellising is used for training and supporting the trees, stout tar-twine is the best tying material, and young pliable Willow growths are frequently used for fastening the trees.

SIMPLE METHOD OF INDUCING FRUITFULNESS.—Much restricted trees on the Pear stock usually form much surplus growth, and if this is annually hard pruned very little fruit results. In all cases where trees on the natural stock are planted, it is advisable to give these good room for extension, or otherwise nothing but severe root-prunings will cause fruitfulness. The simplest method of inducing a free bearing habit, where formerly nothing but wood was formed, is to adopt a complete change in the style of pruning. Instead of cutting back, or even only lightly pruning the young growth, be content to merely thin out freely, leaving well ripened fairly strong shoots wherever there is good room for them to develop. This need not disfigure the trees, but on the contrary, the exercise of a little judgment will give them a more attractive appearance, as well as considerably extend the fruiting area. Nearly all the unpruned branches will, during the coming year, become thickly set with fruit buds, and in all probability this treatment will rapidly lead to a general fruitful habit. The thinning must be persevered with, and two-year-old shoots may be prevented from extending when once got into a free bearing state. These remarks apply to either pyramid, bush, or standard trees.

FRUIT FORCING.

FIGS.—Early Trees in Pots.—When the terminal buds have fairly started advantage may be taken of mild weather for increasing the temperature, as the Fig delights in a good heat, plenty of moisture, and all the light that can be secured. The increased temperature will be the more beneficial if it can be obtained from heat combined with solar influence by day in preference to making any great advance by night. The glass under any circumstances should be kept clean and as free as possible from condensed moisture by changing the atmosphere, especially in the early part of the day. Syringe the trees and walls twice a day according to the state of the weather, and damp the floors in the evening when the weather is dull and unfavourable to the afternoon syringing. See to the fermenting material, and if the heat exceeds 70° to 75° turn the material over as a means of reducing the bottom heat, and setting moisture at liberty. Maintain the night temperature at 55° to 60°, give a little air at 65° when the morning gives promise of an increase from sunshine, and keep through the day under sun heat at 70° to 75°, closing sufficiently early for the heat to rise to 80°.

Early Forced Planted-out Trees.—If the house has been closed and a good body of fermenting material has been introduced but little fire heat will be required by night until the buds show signs of growing, particularly when the trees have been started about the same time for a number of years, but in the case of young trees that have not been forced they will require a somewhat higher temperature to cause them to break freely. Syringe twice a day with tepid water or a few degrees warmer than that of the house, and if found necessary to supply water at the roots use it at a temperature of 80° to 90°.

Succession and Late Houses.—Thin the wood that has reached the extremity of the trellis, wash the trees with warm soapy water, and in the case of scale having appeared a wineglassful of petroleum to a gallon of water may be added with advantage. Thoroughly cleanse the wood-work and glass, and limewash the walls. Remove the old mulching if not already done, and supply a layer of good manure about 3 inches thick. Keep the house cool and dry.

Young Pot Trees.—Prepare for potting young plants intended for fruiting twelve months hence, using good fibrous loam with a fifth of old mortar rubbish, and a sixth of thoroughly decayed cowdung. Train to a clean, straight, single stem, and allow the radiating shoots to form the foundation of a good pyramid. If wanted for early work another season they should be placed in gentle bottom heat by the middle of January in order that they make and thoroughly ripen their growth by the early part of September, it being essential that they have a few weeks' rest before being again started into growth. Cuttings or eyes of kinds to be increased may now be inserted.

PINES.—In most establishments where Pine Apples are grown there is a demand for ripe fruit in May and June. It will be necessary to take into consideration the present condition of plants that are to afford that supply. Where there was a good show of fruit of such varieties as Smooth-leaved Cayenne, Charlotte Rothschild, Black Jamaica, Montserrat, with Black Prince in October and November, the necessity of starting plants now will not be so imperative as where there was not a sufficient number of those varieties showing fruit at the time named, and as fruit of those indicated starting now will not be ripe at the requisite time, plants of the Queen, Enville, and Providence varieties, which require less time to arrive at perfection, should be induced to start their fruit. Select from the successional stock plants that have been subjected to somewhat cool and dry treatment, choosing those that have an enlarged base with a tendency to open in the centre. Place in a light house or pit, and plunge them in a brisk bottom heat of 85° or 90°, the atmospheric heat ranging between 60° and 70° at night, according to external conditions, allowing from 5° to 10° more by day. A genial atmospheric moisture must be kept up about the plants, but not by steaming from the hot-water pipes or syringing the bed between the plants, but by occasionally damping cool surfaces about the house. The soil must be examined once a week, employing tepid water with a little guano or other approved stimulant in it, applying it copiously when needed, and at no other time.

CUCUMBERS.—Young plants coming into bearing should not be over-cropped, assisting them by removing unnecessary fruit blossoms, also male flowers and tendrils. Plants bearing will require to be trimmed at least twice a week, removing all weakly and exhausted growths, reserving as much of the young growths as have space for expanding their foliage. Stop the shoots one or two joints beyond the fruit, but young plants should be allowed more freedom, laying the foundation of a well-furnished plant, avoiding overcrowding. In mild weather the temperature should be 65° to 70° at night. In severe weather 60° to 65° at night is more suitable, by day 70° to 75° with a rise of 10° from sun heat, admitting a little air at 80° if the outside air be moderately warm and soft, but if cold and sharp it is better to allow the temperature to advance a little higher than admit cold air even when the sun is powerful; if the heat is turned off when there is hot sun it will do much to lessen the necessity for ventilation. A little flowers of sulphur dusted on the foliage and hot-water pipes is a good preventive of mildew and red spider. Quicklime rubbed well into the parts affected with canker will subdue it. The floors will need damping in the morning and early afternoon.

Raising Plants.—Sow now or early in the new year for raising plants to put out in pits or frames early in February, which are heated by hot water or fermenting materials. If no convenience exists for raising the plants a bed of fermenting materials should be made forthwith, the seed to be sown as soon as the frame affords a temperature of 70° to 75°. The plants from this sowing will be available for planting to afford a late spring and early summer supply of fruit, either in houses, in hot-water heated pits, or in pits or frames heated by fermenting material under good treatment, fruit being forthcoming in March and early April. No variety surpasses a carefully selected stock of Telegraph for general use, and Cardiff Castle is excellent both in crop and constitution.

MELONS.—Seed to afford plants for the first crop may be sown now, or early in the new year. Fruit from this sowing may be expected in late April or early May. Sow singly in 3-inch pots, filling the pots about half full of soil moderately light in texture, which will allow of soil being added as the seedlings advance, strengthening them wonderfully. They should be kept near the glass, the object being to insure a short stem and sturdy growth. A temperature of 65° to 70° at night and 70° to 75° by day is suitable. Blenheim Orange, scarlet flesh, and Longleaf Perfection, whitish flesh, are excellent varieties.

TOMATOES.—Where plants have not been raised from cuttings made in autumn, sow seed now rather thinly in light soil, and place in a house where there is a temperature of 55° to 60°. We prefer to sow singly in 3-inch pots half filled with soil, and to place them near the glass. The plants are earthed as they require it, and are transferred to 5-inch pots, keeping them well down in the pots. From these they are transferred to the bed, which insures a depth of about 12 inches for soil, the part under being rubble, over and surrounding the hot-water pipes—in fact, the exact counterpart of a Cucumber house. The bottom heat makes much difference, just as it does with Cucumbers, especially for winter and early crops, but it is not essential. The plants should be encouraged to make a sturdy growth, keeping them when in the pots well up the light. Plant them out when they have filled the 5-inch pots with roots in ridges the whole length of the house and about one foot wide at the top, bad in some few days to warm and down to the first leaves, making the soil firm, so as to insure a sturdy growth. The plants must be 18 inches apart. Train to wires a foot from the glass with one stem, keeping off all side shoots, and the plants will be single cordons. Fruit will show right along, therefore stop only when the last truss is gained on the extent of the space. Good loam with a fifth of well decayed manure will grow them well, but some lime rubble, a little wood ashes and charcoal are advantageous. A 2-foot width of border is ample, the plants being earthed as the roots protrude. Surface dressing and liquid manure can be given when the roots have possession of the soil. When the first cordons are ripening the first clusters of fruit, a shoot can be encouraged from the base, and it can be taken up so as to succeed the one advanced in fruiting, and a successional supply of fruit thereby be maintained for a lengthened period.

Growing in Pots.—Instead of planting out the Tomatoes can from the 5-inch be transferred to 10-inch pots, placing the base of the ball on the drainage or a very little soil over it, which will leave space for surface dressings. They are to be treated similarly to the other plants.

Cutting Plants.—We prefer these for early fruiting. The cuttings are struck in September, kept near to the glass in 5-inch pots in a temperature of 60° to 65°, with 10° advance from sun heat. The plants get tall, but that makes no matter as we prepare the ridges as before stated, and by the middle of December or before the new year the plants are showing trusses of bloom, and we layer them in the ridges at the required distance at the joint below the truss of bloom, the plants being kept in the pots until the layer is well rooted and then detached. In consequence we have fruit from the lowest part of the plants, and they fruit right away. Those for pots are layered into their larger sized pots, they being about one-third or half filled with soil, the bending over not interfering with the work of layering, only it must be done carefully. The 5-inch pots can be raised so as to facilitate layering into the fruiting pots. The cutting plants fruit earlier and give as a rule better shaped fruit than those from seed. Afford a night temperature of 55° to 60°, 60° to 65° by day, and 70° to 75° from sun heat, ventilating from 65°. In dull damp weather a crack of air should be left on constantly, as a close atmosphere is very enfeebling. When in flower ventilate and rap the base of the trusses in flower to distribute the pollen. Fully one-third of each leaf should be pinched away, as it assists the fruit in swelling, practising it early.

CHRISTMAS.

To the Editor and to all our friends a Christmas greeting. Again a year has sped, the wings of time have carried us over another spring, and summer, and autumn. The book of the past lies open to our view; the book of the future lies before us, and its unsullied pages mock our most anxious inquiries. New hopes, new expectations cheer us on our way, and failure in the past only spurs us on to hope for success in the time to come. The old year is in the throes of death, the new year is not yet born, but soon the old year and the new-born season must meet in close embrace, and then must part for ever. As the changing seasons give place one to another, so 1888 and 1889 must meet, and then the old year is left behind, and the new year pregnant with great issues grows on apace. But with us the case is otherwise. The efforts of the past can only bear fruit in the future; the tree planted in the present year will give no return until a new year's sun has coaxed it into growth; the stock of bees so carefully tended last autumn lies inactive and without profit to us until the sun of the future spring time rises high in the heavens and causes the myriad flowers and blossoms to yield their harvest of nectar to

delight him to whom the bees themselves must look for help in the dead time of winter. From the ice-bound earth will soon arise plant life, and soon the lambs and other living creatures will begin once more to herald the approach of the more temperate months, while the lengthening days will give us more time in which to perform the manifold duties cast upon us.

Such are the thoughts of many who give themselves time for reflection at this period of the year. Each one may learn a lesson which will be of value in the future by showing how much depends upon the past. Bee-keepers look back on the summer of the present year with some regret. The spring was unusually severe and long, and when at last hopes were aroused it was only for a few days, when once more a spell of cold and wet dashed to the ground the unrealised expectations and left some with a scanty surplus, and compelled many even to give a supply of food to tide over the then present fear of actual starvation. On the other hand, and perhaps as a direct consequence of lessened production, we find that higher prices have prevailed, and accordingly some bee-keepers have from a moderate yield reaped a profit even greater than they would have done had the season been more favourable.

Some new ideas, or at any rate some ideas which seem likely to be carried out in a practical form, have been brought to the front during the present year, and first amongst these we should be inclined to place "A Hallamshire Bee-keeper's" glass sections, although we have not yet had an opportunity of seeing one of them. The beauty of glass vessels is well known, and it is impossible to imagine a fairer sight than pure honeycomb in good clear glass, showing every tint and shade of the honey in the cells adjoining the glass, and showing to the very best advantage the skilled work of the delicate bee. For cleanliness and beauty the idea can certainly not be surpassed; but, on the other hand, the expense must be kept down, otherwise we fear that the sordid public of to-day will prefer to buy a cheaper yet wholesome package. The craze for low prices puts a heavy brake on our utmost efforts, and yet we can see that beauty is not slightly regarded by the most economical, provided the sum they have to pay in order to obtain a goodly appearance is not too high. In large towns, where there are many wealthy merchants and others, the price of a package of honey is not material, but the dealers in smaller districts inform us that, provided the honey is good and pure, the purchaser does not pay as much attention as we should expect to the form of the vessel. We earnestly hope that the glass sections may be introduced, and that they will be sold at as low a price as possible, having regard to the profit due to those who have an interest in their production and sale.

What of the future? There is no need to despair. Our prospects, on the whole, are as good as they were at this time twelve months ago. If bee-keepers did not attend to their bees in the summer and autumn, they must not forget that the man who sows thistles will reap thistles, and the man who sows corn will reap corn. With proper care every stock should be in good condition now, and unless the queen dies in the coming months of spring should be ready to take part in the early harvesting operations which are generally commenced in May. Weakly stocks are, broadly speaking, not profitable; with care they may sometimes do well, and as "A Lanarkshire Bee-keeper" has shown, in some cases they have given very good results; but the oft-reiterated advice to keep strong stocks only is still the one which we shall offer, although there are circumstances in which it may be not only wise but essential to keep a small stock for the sake of the queen, which must otherwise be destroyed.

Spare queens in the coming spring will be very valuable. We had not intended to venture into the region of prophecy, but we fear that many queens will be found wanting before the end of April, and special care and attention will consequently be required to avert evil results. What to do in these cases must occupy attention in the issue of another week. Another feature of the present year has been the increased neatness in which honey has been put

upon the market. The slovenliness of the past has been swept away, and fair white sections and clear glass bottles may now be seen where once were found sections of a very doubtful colour and pots and mugs of a decidedly unappetising hue. We have been led to write at further length than it was our intention to do, and in closing we may assure bee-keepers that the honey yield of the past year was phenomenally bad, and that there is no reasonable fear of being visited with such another for some seasons yet to come.

It would seem that every subject must be exhausted after writing for two or three years with some regularity upon the same industry, but in the future we hope to be able to find something of interest and of importance to write about for the good of bee-keepers in general; and it is a special pleasure to notice that the regular contributors to the bee-keeping columns agree—if not in all points, at any rate in the main—with one another, and even when points of disagreement are discussed they are discussed with courtesy and without unnecessary fervour.—FELIX.

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Unanswered Letters (To Inquirers).—In consequence of the Christmas holidays the pages of the present issue of the Journal had to be made up last Friday, therefore answers to some questions are of necessity deferred.

Books on Botany (R. C., Newcastle).—You will find the following works useful, taking them in the order named as you advance:—Sir J. D. Hooker's "Botany Primer" (Macmillan & Co., Bedford Street, Strand, London); Professor Oliver's "Elementary Botany," published by the same firm; and Henfrey and Masters' "Course of Botany" (Van Voorst, 1, Paternoster Row, E.C.). You will probably find the first two sufficient at first, and they can be purchased for 5s. The other is a much more expensive work. In studying botany you must not rely upon books alone, but strive to gain a practical knowledge by closely examining all the plants possible, and endeavour to understand their structure. One of the great advantages of attention to botany is that it cultivates the powers of observation, no mean help to a person in any employment.

Oxalis Culture (O. S. W.).—Of the easiest culture, we are surprised you cannot induce them to flower, and grow luxuriantly. It appears you give them too liberal treatment, and keep in the shade at some distance from the glass in a shaded and moist position. Grow them on shelves near the glass, potting when they are beginning to grow in a mixture of three parts light fibrous loam, one part leaf soil, and two parts sandy peat, with a part of silver sand, watering moderately until in free growth, increasing the supply with the growth, and after flowering, or the growth is complete, diminish the supply, ceasing watering when the leaves become yellow, and keeping dry until the plants again start into growth. They do well in a light airy position in a greenhouse. Their great bane is too much water and shade.

Poinsettia Treatment after Flowering (Amateur).—Keep the plants dry, not allowing the wood to shrivel, and cut down in March, inserting what cuttings are required, selecting the firm ripe wood, and strike in brisk bottom heat. The temperature after flowering should be 50° from fire heat, and 5° higher by day from the same means. Water moderately after the plants are started into growth, sprinkling the stems twice daily, which will be sufficient moisture to cause them to start into

growth, and repot when the plants have shoots an inch long. A moist atmosphere, with careful watering at the roots, taking care not to over-water nor to allow the plants to flag, keeping near the glass, and well ventilated, so as to induce a sturdy growth, and a temperature 55° to 60° from fire heat, and 10° to 15° or 20° rise from sun, keeping lower and drier after early August.

Forcing Imported Lily of the Valley (W. R.).—It is not unusual for imported clumps to remain dormant if placed, immediately after potting, in a high temperature. Pot and plunge them in a bottom heat of 75° and not exceeding 90°, and cover with inverted flower pots, taking care that the soil does not become dry. Every crown will grow, and when the spikes are about 5 or 6 inches high then withdraw the pots from the hotbed and place them in a house with a temperature of 65° by day and 55° at night, in which they will expand the flowers and develop the foliage. In the new year they will succeed admirably in a vinery started at that time; but the plants must be brought on gradually with the Vines or they will remain dormant or go "blind," which is obviated by bottom heat or a rising temperature, commencing from a low one. Several articles have been published on this subject recently. See pp. 488 and 512.

Asparagus Neglected (A. F.).—Your best plan will be to prepare a piece of ground by trenching and enriching with manure. This to be done as soon as possible, so that it can be exposed to the action of frost, and early in the spring, when sufficiently dry to work cleanly, fork it well over again so as to bring it into a loose friable condition. Immediately you perceive the Asparagus above ground fork up the roots carefully by undermining them, and plant them again in the new bed. This work must be done with as little exposure as possible to the roots. If they are transferred without being dried during the process of removal, and are planted in drills or trenches sufficiently wide so that the roots can be spread out without being doubled, and an inch or two of light soil, such as decayed leaves or vegetable soil, is worked amongst them, levelling-in with the ordinary soil and watering with tepid water, they will grow. They will not grow with certainty if removed when in a dormant state, and you cannot eradicate the weeds without digging up the Asparagus.

Pruning in Winter and Spring (Staples).—The pruning of all kinds of fruit trees and bushes may be completed if the weather is not too severe. A little frost renders the ground clean for the operator, but we prefer warmer days as a rule for pruning, yet where there is much of such work to be done it is sometimes necessary to do it during the cold winter days. Peaches and Nectarines on walls may be left until the early part of the new year, when it is advisable to unfasten them and allow them to remain from the walls as long as it is possible in order to retard their time of blooming. Plums do well on the spur system generally, and should have all natural spurs retained. Cherries bear their fruit in exactly the same way, but with Morellos the wood oftentimes becomes so thick as to exclude light unless judiciously thinned out from the centre of the bushes. Black Currants produce their fruit generally from the young wood of the past season. Young growths, therefore, should by all means be encouraged, merely removing some of the old shoots to open the centre of the bushes, and shortening the points of straggling shoots, which is all the pruning the bushes require. Red and White Currants bear their fruit principally on spurs, it is therefore advisable to prune these much closer than the Black varieties. Gooseberries carry their fruit in a similar manner, producing it on both the spurs and on the past summer's growth; therefore retain a sufficient number of young shoots at moderate and regular distances apart, keeping the centre of the bushes open that the sun and air may act on as large a surface of foliage as possible.

Horseradish Culture (Inquirer).—The number required has been long out of print, but the information given by an experienced grower was as follows:—As soon as the leaves are off the plants in October or November we take out a trench at one end of the bed, as is usual in ordinary trenching, and by means of fork and spade turn over the whole of the bed down to the clay, carefully picking out the roots as whole as possible, and manuring as the process goes on. The bed is then made level ready for replanting. The roots are then looked over; all that is fit for kitchen use are dressed and laid aside for that purpose, and all the long thin roots of the thickness of a quill stripped of all side roots are laid in bundles for replanting. With a long dibber (or an ordinary Dahlia stick will do), make holes 18 inches or 2 feet deep, 6 inches apart, and 1 foot between the rows. Into each of these holes we drop one of these long roots, and then fill the hole up with fine dry soil from under the potting bench. These make nice useable roots the first season, but of course if they were left for two seasons they would be much better. This annual planting has many advantages. In the first place, a very small bed will grow sufficient for the supply of most families. This struck me very forcibly on entering a very old kitchen garden a few months ago, where was to be seen a bed of Horseradish some 15 yards long by 5 or 6 wide, which apparently had not been disturbed, except in digging roots up for use, for fifteen or twenty years. In contrast to this we have dug from a bed 15 feet by 8 sufficient good roots to supply an ordinary family for twelve months. In the second place, the ground is being cultivated. It is annually improving; and the plants being in rows, it can be kept clean by means of hoeing, the same as any other crops, instead of becoming a nest of weeds, as is too often the case; for it is no uncommon thing to find weeds seeding in the Horseradish bed at places where they would not be tolerated anywhere else. In the third place, there is no such thing as shouldering a pick

when grim John Frost resists the spade in the gloomy winter months. The roots are laid regular in layers one above another with soil between, covered over with soil. A little litter keeps out frost and mice. It is always accessible without the aid of either pick or spade.

Raising Ash Trees from Seed (W. R.).—Raising the trees from seeds appears to be a much slower process than you imagine, and they must be prepared in a very different manner from that indicated in your letter. Sowing on land infested with twitch would result in failure, especially as the seed is long in germinating the twitch would inevitably gain the ascendancy over the seedlings. In Brown's "Forester" the following instructions are given on this subject:—"The seeds of the Ash are enclosed in what is termed samaras or keys, which are generally ripe for gathering about the end of October. When gathered for the purpose of sowing, the seeds should be mixed with a quantity of dry sand or light dry earth, in which they should be kept for eighteen months, in order to rot off the outer coat; and in order the more effectually to insure this, the whole mass of seeds and sand should be turned every three months. This mass of sand and seed should not be much over 1 foot in depth, as, if more, it will be liable to heat, and in consequence the vitality of the seed would be injured. In the second March after they are gathered the seeds should be sown in rows rather thinly, and upon any moderately well pulverised soil. They are sure to come up thickly and confine one another if not sown thin, and the covering of earth should not exceed three-quarters of an inch. In the following spring the plants will be ready for being transplanted into the nursery rows, which may be 15 inches one from another, and 4 inches plant from plant in the rows. When the plants have stood two years in the nursery rows they may be removed and transplanted into the forest ground; but if wanted of a larger size they may be left a year longer." Would it not be better to purchase the requisite number of trees of different kinds for planting? This is the usual custom, unless time is of little moment. In any case you will find it advantageous to have the land thoroughly cleaned, then if the ground is planted, a crop of Potatoes might be grown between the trees for a year or two, which would partially defray the cost of the work, and the working of the ground in planting and digging up the crops would be favourable to the growth of the trees and prevent the luxuriant growth of twitch. We have established plantations very much larger than that you contemplate in the manner alluded to, and the results were perfectly satisfactory.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J., Surrey).—1, *Adiantum tenerum*; 2, *Asplenium bulbiferum*; 3, *Asplenium cicutarium*; 4, *Nephrolepis tuberosa*. (W. R. S.).—1, *Odontoglossum Rossi majus*; 2, *Masdevallia Lindeni*; 3, *Laelia autumnalis*; 4, *Laelia anceps*; 5, *Zygopetalum crinitum*. (Reader).—1, *Adiantum trapeziforme*; 2, *Pteris serrulata*; 3, Insufficient, without spores.

COVENT GARDEN MARKET.—DECEMBER 26TH.

No alteration. All classes of goods well supplied.

LESSONS OF THE YEAR.

If it be true that in 1887 we reached the lowest depths of the agricultural depression, it is, we fear, equally true that the present year has witnessed no great improvement in the position of farmers generally. Adverse weather has, undoubtedly, been the chief cause of this, for if only we had been able to harvest and save the abundant grain crop in high condition, and have got a little more quality in the hay, there would certainly have been fair reason to record a decided improvement in agriculture all round. Horses, sheep, cattle, and pigs have all been profitable, and they continue so. The impetus given to dairy farming tends to a marked improvement in the home trade; really good samples of new Wheat command prices that approach closely the much-desired 40s. per quarter, and old Wheat was sold at really remunerative prices. The crops of Peas and Beans were very abundant; so, too, were Oats and Barley. But, though there was a full and perfect development of Barley grain, the trying changes of weather rendered it thick-skinned and discoloured, and prices have been disastrously low, to the serious loss of corn farmers. Wet weather spoilt much hay, and the entire crop is low in quality. Prices for good hay have naturally risen, but then very few farmers have good hay to sell. Root crops are very abundant, so abundant that many farmers are puzzled what to do with them, and are giving them to anyone who will put sheep on the land to consume them. Of course the proper thing is for more sheep to be purchased to be folded upon the Turnips, but a want of means prevents very many farmers from doing this, and they are unable to take advantage of their opportunity. We have seen some of the Turnips being chopped in pieces with hoes and ploughed in, and this will doubtless enrich the land for Barley, but it cannot answer to grow Turnips for such a purpose. A natural outcome of the abundance of roots and green crops was an increasing demand for sheep; prices have risen accordingly, and those who have sheep to sell find the trade very profitable.

Pigs have been more useful than usual, as they have been turned to excellent account to consume inferior Barley. It is matter for regret that the farmer is unable to derive the full benefit from pigs that is possible. What he really ought to do is to strive to get rid of all those who come between him and the consumer. If he would only be at the trouble to establish a trade for dairy fed pork, sausages, hams, bacon, and lard, he is bound to add greatly to his

profits. "Live and let live," is, no doubt, a very good proverb rightly applied, but the farmer is justified in looking more closely after his own interests just as much as anyone else, and to ask him to refrain from interference with the pork butcher's trade is about as sensible as to assure him it is a point of duty with him to employ so much labour upon his farm. The farmer is not a philanthropist; he invests a certain amount of capital in land, and he is bound to get the best interest he can from his investment.

Throughout the year we have repeatedly heard much talk of the necessity for State aid, in the form of protection or fair trade; of an uniform rate of exchange throughout the dominions of the empire, in order to set aside the unfair advantage conferred upon the Hindoo ryot, by the difference in value of the rupee in England and in India; of relief in the burden of tithes and taxes upon the land; of tempting reforms promised by our rulers; of a minister of agriculture to give especial attention to our interests. But what has come of it all? why, literally nothing, and now, at the end of another year the farmer ought to see clearly that the best help of all for him is self help.

On December 10th, at the Surveyors' Institution, Mr. Wells read an interesting paper on "The Prospects of an Agricultural Revival." He gave elaborate details of Wheat culture by our foreign competitors in India, France, America, and Russia, and by comparison and otherwise strove to show that our prospects in future competitions with those countries were at least hopeful; but he had really nothing definite to go upon, and mere conjecture or fanciful deduction, however interesting, cannot be taken as a guide for action. He, in common with other optimists, said that there was more inquiry for farms, which we may assume by inference is to be taken as an indication of tenants being available for farms in hand. Well, now, we and several other land agents well known to us have many farms to let, but very few really desirable tenants were to be heard of last Michaelmas. It had just come to this in letting a farm, an agent dare not take any conclusive step about it till he obtains a satisfactory bankers' reference from a prospective tenant, and how few of them can pass satisfactorily through such an ordeal?

On the whole, then, if the end of another year has brought us to no higher degree of success, it has certainly brought no catastrophe in its wake, and we have still reason to be hopeful about the future. More than this, we are resolved, as we doubt not all our readers are, to leave nothing undone to render the new year a prosperous and successful one.

WORK ON THE HOME FARM.

The end of the year finds us with much more work upon our hands than usual, and we hope to have no snow yet, for we are doing our utmost to bring up arrears of ploughing. The past year will certainly be memorable for its late harvest and the late sowing of winter corn, which on the whole looks remarkably well. But we are anxious to plough every foot of land we can, both to be ready for spring work and to expose the soil to beneficial action of frost and snow. Steam tackle has been used to advantage this winter, but we object strongly to its reckless use in the same way upon all land. If we intend laying down land to permanent pasture we break up soil of every kind deeply with a steam cultivator. But for corn this plan does not answer, for if a cold clay subsoil is brought to the surface to be sown with corn in spring, it would indeed prove difficult to enrich it sufficiently to insure a crop. By all means stir the land deeply, but first turn over the surface furrow, and then turn up the subsoil, always keeping the surface furrow uppermost.

Glad indeed are we to see so much pipe draining being done this winter, for it is a sign that landlord and tenant are united in their efforts to improve the land. Depend upon it under-draining unlocks the soil and insures it full benefit from all subsequent culture. We are aware that farmers still exist who proclaim their disbelief in drainage; living examples are they of ignorance and conceit, who are not to be taught either by the lessons of experience or science. Keep the land waterlogged, and all your efforts to enrich it with manure in view of obtaining full crops will be vain, for the wet soil continues cold, inert, and practically impervious to the air and warmth even in summer, and crops cannot thrive. Relieve it of water by judicious drains; air and warmth enter the very water itself as it passes through, and always leaves some addition to the store of fertility, and we have no difficulty in rendering most of the fertility in the soil active and useful for plant food. For heavy clay land bush drains are perhaps preferable, as they open up the soil better than pipes ever can do.
